Malignant jaundice in the dog, W. ROBERTSON (*Jour. Comp. Path. and Ther.*, 14 (1901), No. 4, pp. 327-336, figs. 5).—The author describes in detail the symptoms of this disease and briefly reviews the literature of the subject. Notes are given on the post-mortem lesions found in dogs affected with the disease and on the nature of the blood parasite. Numerous remedies were tried without much success. The best results were obtained from the administration of calomel and quinin. Evidence is presented to show that the blood parasite which causes this disease is conveyed from one animal to another through the agency of the dog tick (*Hemaphysalis leachi*).

Intravenous injections of corrosive sublimate, A. SERAFINI (*Pub. Ist. Univ. Padova*, 2 (1902), XIV, pp. 17; *extr. from Riforma Med.*, 18 (1902), No. 79-80).—Experiments in intravenous injections of corrosive sublimate indicated that this substance does not exercise a germicide action upon the organisms of anthrax and fowl cholera in solution in the ratio to the weight of the body of 1:360,000 or in the ratio to the weight of the blood of 1:30,000. The author does not believe that this method can become of general therapeutic value in the treatment of infectious diseases.

The causes which determine the absence of phagocytosis in the last stages of fowl cholera in rabbits, B. WERIGO (*Arch. Med. Exper. et. Anat. Path.*, Paris, 1. ser., 14 (1902), No. 2, pp. 156-202).—The author conducted a large number of experiments, during which rabbits were inoculated with organisms of fowl cholera. It was observed that during the last stages of the disease the phenomenon of phagocytosis was absent. The author investigated the cause of this phenomenon and concludes that the absence of phagocytosis in the last stages of the disease does not depend upon any changes in the phagocyte cell. It is also believed that a change of the medium or the saturation of the organic liquids with the bacterial

toxins can not be considered as causing a cessation of phagocytosis, except to a very limited extent. The two causes of the absence of phagocytosis are believed to lie principally in alterations in the bacteria which protect them against the phagocytes. During the first stages of the disease the bacteria appear to exercise an irritating effect upon the phagocytes, by means of which the former become located and are surrounded and destroyed by the phagocytes. Later this influence appears to be lost and the phagocytes seem to be unable to find the pathogenic organisms.

Bacillar septicemia in chickens, F. FUHRMANN (*Mitt. Naturw. Ver. Steiermark, 1901, No. 38, pp. 248-255, pl. 1*).—The author investigated a disease of chickens which ran a course without producing any observable pathological changes in the internal organs. Detailed notes are given on the behavior of the bacillus on various nutrient media. The bacillus did not coagulate milk and was decolorized by Gram's method. From 2 to 4 flagella were observed on each bacillus. No spore formation occurred. The optimum temperature was about that of the body. Pigeons and mice were found to be immune to subcutaneous and intramuscular infection. Chickens, spotted rats, rabbits, and guinea pigs, on the other hand, were very susceptible. So far as the author's observations go, the filtrates from cultures of bacillus are not toxic. It is believed that the organism in question belongs to the group of coli bacillus.

Goose septicemia, C. CURTICE (*Rhode Island Sta. Bul. 86, pp. 189-203*).—A serious outbreak of a fatal disease among geese occurred in a feeding plant at Adamsville, R. I. Among a large number of geese which had been bought in different parts of the State about 3,200 were affected and died. The death rate averaged from 5 to 30 per day and reached 60 on 1 day. A similar outbreak occurred at Little Compton, during which 500 geese, or about 20 per cent of the whole flock, died. The symptoms of the disease were seldom observed in their entirety. Some of the geese died within 5 minutes after the first appearance of the disease, and as a rule the course of the disease was not longer than 36 hours. Apparently no cases recovered. Post-mortem examinations showed quantities of mucus in the throat and nose, congestion of the blood vessels of the head, catarrhal products in the intestines, small hemorrhages in the walls of the intestines, and minute yellow or whitish spots on the liver. The bacteriological work was chiefly performed by Dr. Theobald Smith, whose notes are included in the bulletin. A bacterial organism was isolated by Dr. Smith from the blood, liver, or mucous exudate of the affected geese. The organism is oval and stains at the poles. It belongs to the group of hemorrhagic septicemia. Inoculation experiments showed that this bacillus is pathogenic for rabbits, guinea pigs, pigeons, mice, ducks, and geese, whether administered hypodermically or by way of the mouth. Young geese fed on small pieces of the intestine and liver from diseased geese were found dead the next morning and they showed similar post-mortem appearances to those observed in cases of natural infection. It is believed that infection in geese takes place by way of the mucous membrane of the head. Experiments with hens indicate that this animal is immune to the disease, while in 1 case ducks were not affected by feeding with virulent material, but succumbed to hypodermic inoculation. It is suggested that while infection takes place through the mucous membranes of the head, it probably occurs only in animals in which there are lesions of these membranes. Treatment must be preventive, medicinal treatment being useless. On the premises where the most serious outbreak occurred the geese were fed in lots of 300. It is suggested that they be divided into smaller lots, and that the premises be thoroughly disinfected from time to time. After the larger outbreak mentioned above had occurred the feeding plant was used for fattening ducks without any case of the disease having appeared in the latter.

Diphtheria of birds, C. GUÉRIN (*Ann. Med. Vet., 51 (1902), No. 5, pp. 259-272*).—A careful study was made of the symptoms, pathogenesis, and treatment of this disease. An organism was isolated which, when inoculated into healthy birds produced the same symptoms which were observed in cases of natural infection. The pigeon

was found to be most susceptible to the disease. In this bird the virulence of the organism was increased and fixed by repeated inoculations. Experimental transmission of the diphtheria of birds was found to be an easy matter in the pigeon, both by inoculation and by injection of virulent products, especially the excretions of diseased birds. It was found possible to produce an active permanent immunity to the disease in susceptible animals by inoculation of an attenuated virus into the peritoneal cavity. Hypodermic inoculations were without effect. An antibacterial preventive serum was obtained from a horse by means of which active immunity could be produced in susceptible animals through serum vaccination.

Infestation of ducks with *Dermanyssus avium*, R. KLEE (*Deut. Tierärztl. Wchnschr.*, 9 (1901), No. 1, p. 2).—An account is given of a serious infestation of ducks from this mite. It is recommended that ducks be kept in special inclosures or buildings and not allowed to occupy buildings along with chickens and pigeons, since infestation by this mite may be thus spread from the pigeons and chickens to the ducks.

AGRICULTURAL ENGINEERING.

Irrigation of rice in the United States, F. BOND and G. H. KEENEY (*U. S. Dept. Agr., Office of Experiment Stations Bul. 113*, pp. 77, pls. 29, figs. 10).—In this bulletin Mr. Bond describes the rice industry of Louisiana and Texas, and gives measurements of the quantities of water used in irrigating rice in these States. He also discusses the water laws and the difficulties which have arisen from overappropriation of the streams. Mr. Keeney's report deals with the rice industry in the South Atlantic States (North Carolina, South Carolina, and Georgia), and is almost wholly descriptive.

The control of water from melted snow by means of terraces, P. JANKOVSKI (*Zhur. Opitn. Agron. [Jour. Expt. Landw.]*, 3 (1902), No. 3, pp. 348-354).

List of references to publications relating to irrigation and land drainage, ELLEN A. HEDRICK (*U. S. Dept. Agr., Library Bul. 41*, pp. 181).—The list, which was prepared in cooperation with this Office, "includes references to irrigation and land drainage principally, but . . . includes, also, references to a few allied subjects, such as hydraulics, and some departments of engineering. No attempt has been made to catalogue articles in periodicals except in the following cases, namely: Transactions and Proceedings of the American Society of Civil Engineers, Transactions and Proceedings of the Technical Society of the Pacific Coast, Minutes of the Proceedings of the Institute of Civil Engineers, Journal and Proceedings of the Royal Society of New South Wales, and Annales des Ponts et Chaussées: Mémoires et documents. The work has been done in the libraries of Washington containing the largest collection of books on the subjects mentioned. Books which are available for reference in these libraries are indicated by abbreviations after the entries."

Tests of agricultural machines at Plessis, E. LEPLAE (*Rev. Gén. Agron. [Louvain]*, 11 (1902), Nos. 7-8, pp. 376-382; 9, pp. 390-394, fig. 1).—This article refers briefly to Ringelmann's work in the testing of agricultural machinery, and discusses the development and perfecting of the plow and steam cultivation.

Report on agricultural implements and machines at the agricultural exposition of Hasselt in 1900, J. PYRO (*Bul. Agr. [Brussels]*, 18 (1902), No. 4, pp. 549-593).—A brief discussion of the relative merits of different forms of plows, grain seeders, fertilizer distributors, harvesting and thrashing machines, rakes, mills, feed cutters, petroleum locomobiles, etc., displayed at this exposition. Attention is also called to a simple but apparently efficient device for equalizing tension and transmitting force, in case of horses, without shock.

Notes on the application of cold to agricultural products in commerce (*Rev. Gén. Agron. [Louvain]*, 11 (1902), No. 7-8, pp. 363-375).—Brief notes are given on the commercial application of cold in the storage and transportation of agricultural products.

MISCELLANEOUS.

Fifteenth Annual Report of Maryland Station, 1902 (*Maryland Sta. Rpt. 1902, pp. XVIII + 201*).—This contains the organization list of the station; a report of the director enumerating the lines of work pursued by the different departments and giving notes on the station library, agricultural museum and exhibits, etc.; observations on precipitation and temperature; and a financial statement for the fiscal year ended June 30, 1902. Reprints of Bulletins 77-84 of the station on the following subjects are appended: The comparative digestibility of raw, pasteurized, and cooked milk (E. S. R., 13, p. 674); dehorning of stock (E. S. R., 13, p. 895); the disinfectant properties of washing powders (E. S. R., 13, p. 1020); acute epizootic leucoencephalitis in horses (E. S. R., 14, p. 91); soils and fertilizers for greenhouse crops (E. S. R., 14, p. 38); thinning fruits (E. S. R., 14, p. 253); an inquiry as to the causes of pithiness in celery (E. S. R., 14, p. 250); and some feeding experiments with cows (E. S. R., 14, p. 487).

Proceedings of the fifteenth annual convention of the Association of American Agricultural Colleges and Experiment Stations, A. C. TRUE, W. H. BEAL, and H. H. GOODELL (*U. S. Dept. Agr., Office of Experiment Stations Bul. 115, pp. 134, fig. 1, charts 8*).—This is a detailed account of the proceedings of the convention held at Washington, D. C., November 12-14, 1901 (E. S. R., 13, p. 507).

Statistics of the land-grant colleges and agricultural experiment stations in the United States for the year ended June 30, 1901 (*U. S. Dept. Agr., Office of Experiment Stations Bul. 114, pp. 39*).—A summary of the statistics relating to the stations appeared in E. S. R., 13, p. 700.

Agricultural experiment stations and experimental fields, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 4 (1902), No. 38, pp. 365-367*).—This article traces briefly the history of agricultural experiment stations in France and explains and illustrates the work they may do for the benefit of agriculture.

Demonstration fields—their organization, object, and uses, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 4 (1902), No. 37, pp. 337-340*).—This article explains the practical usefulness of demonstration fields and urges their more general establishment throughout France.

History of Ohio agriculture, C. W. BURKETT (*Concord, N. H., 1900, pp. 211, pls. 4*).—This book gives an account of the progress and evolution of agriculture in Ohio. Soil, climate, special means of transportation, crops of various kinds, stock raising, farm implements and machinery, and agricultural education are discussed.

Report on Hungarian agriculture, C. BARDOÛIN (*Bul. Min. Agr. [France], 21 (1902), No. 2, pp. 441-450*).—A brief report on agriculture in Hungary, containing in addition to some general statements and statistics notes on rotation of crops, the use of fertilizers, pasturing, and the culture of corn, oats, forage beets, and catch crops as practiced in that country.

Sources of the agricultural imports of the United States, 1897-1901, F. H. HITCHCOCK (*U. S. Dept. Agr., Section of Foreign Markets Bul. 28, pp. 132*).—Of the agricultural imports of the United States during the fiscal year 1901 Brazil supplied 13.65, Cuba 9.88, the United Kingdom 7.53, Germany 7.19, Japan 5.26, and France 5.15 per cent. The total value of the agricultural imports during 1901 was \$391,931,051 and the average value for the 5 years covered by this report was \$376,549,697. A similar statistical report for the years 1896-1900 was published as Bulletin 24 of the Section (E. S. R., 13, p. 494).

Distribution of the agricultural exports of the United States, 1897-1901, F. H. HITCHCOCK (*U. S. Dept. Agr., Section of Foreign Markets Bul. 29, pp. 202*).—Of the agricultural exports of the United States during the fiscal year 1901, the United Kingdom received 52.16, Germany 15.22, the Netherlands 5.36, and France 5.28 per cent. The total value of the agricultural exports during 1901 was \$951,628,331, and

the average value for the 5 years covered by this report was \$827,566.147. A similar statistical report for the years 1896-1900 was published as Bulletin 25 of the Section (E. S. R., 13, p. 494).

Agricultural returns for Great Britain for 1901 (*London: Board of Agriculture, pp. 27*).—Tables showing the estimated total produce and average yield per acre of the principal crops, with particulars for each county of Great Britain and a summary for the United Kingdom.

Crop statistics for the Northwest Territories in 1901 (*Rpt. Dept. Agr. Northwest Territories, 1902, pp. 25-32*).—A full account is given of the manner in which crop statistics are obtained. A table shows the total and average yield and the acreage of wheat, oats, and barley for 1898-1901, inclusive.

By-products of the starch industry in the United States (*Jour. Soc. Arts, 50 (1902), No. 2592, pp. 737, 738*).—A brief note on by-products obtained in the manufacture of starch from cassava, potatoes, corn, wheat, and rice.

The utilization of wastes and by-products, H. G. KITTRIDGE (*Twelfth Census United States, Census Bul. 190, pp. 26*).—A general discussion of the uses made of the by-products and wastes of various industries, as follows: Iron and steel, lumber and timber, paper making, slaughterhouse products, woolen and cotton industries, cotton oil, leather, dyeing, silk, starch, old rubber, breweries, tin, mussel shells, glass, ashes, corn pith, glycerin, printers' ink rollers, powdered milk, and corn oil.

Notes on miscellaneous work, P. BONÂME (*Rap. An. Sta. Agron. [Mauritius], 1901, pp. 25-37*).—Brief notes are given on the character of the season of 1901-2 in Mauritius as affecting the yield and quality of crops, especially sugar cane; the fertilizing value of organic nitrogen from different sources; the composition and food value of corn meal; the composition of twigs of *Typhonodorum lendleyanum*; and the damage caused by rats on sugar plantations with means of prevention.

Index to the yearbooks of the U. S. Department of Agriculture, 1894-1900, C. H. GREATHOUSE (*U. S. Dept. Agr. Division of Publications Bul. 7, pp. 196*).—This is a combined subject and author index and is essentially a continuation of an index to the annual reports of the Secretary of Agriculture for 1837 to 1893 published as Bulletin 1 of the Division.

NOTES.

ALABAMA COLLEGE AND STATION.—C. C. Thach, president of the college, has been made acting director of the station. R. S. Mackintosh, assistant horticulturist of the Minnesota Station, has been elected professor of horticulture in the college, and horticulturist of the station. The department of horticulture has been separated from that of biology, and the chair made a full professorship. The greenhouses are being repaired, and improvements made in other station buildings.

COLORADO COLLEGE AND STATION.—At a recent meeting of the State board of agriculture Miss Theodosia G. Ammons, professor of domestic economy, was made dean of women's work in the college. W. R. Thomas has resigned from the board to become professor of constitutional and irrigation law. J. S. Titcomb, former deputy State engineer, has been made assistant in the department of irrigation engineering. A new department of electrical engineering has been established, and L. D. Crain, instructor in mechanical engineering, has been made professor. The course will be opened with the next college year, beginning September first. A new building, to be a central heating plant and also to contain rooms for the department of electrical engineering, is being constructed. An enlargement of the main building, giving increased seating capacity in the chapel, has been provided for. The State legislature will be asked for an appropriation of \$75,000 for a building for the offices of the experiment station and for the department of civil and irrigation engineering. The State board of agriculture has transferred \$1,000 from the college funds to the station, for expenditure under the supervision of the director.

IDAHO UNIVERSITY AND STATION.—At a recent meeting of the board of regents H. T. French, agriculturist of the station, was made director. F. A. Huntley, horticulturist of the college and station, has resigned, to take effect January 1, 1903.

KANSAS STATION.—The annual report of the station states that during the past fiscal year (1901-2) the station published 7 regular bulletins, in editions of 25,000 to 27,000 copies; an index to the bulletins for the year; and 23 press bulletins, the latter in editions varying from 3,600 to 5,000 copies, except in one instance in which 17,000 copies were printed. During the year the station commenced operations at the Fort Hays Branch Station, on a part of the old Fort Hays reservation. Fields of sorghum and Kafir corn, sown alone and mixed, barley, macaroni wheats, millet, corn, soy beans, cowpeas, *Bromus inermis*, alfalfa, Kansas stock melons, peanuts and garvansas, and potatoes were grown, a grass garden with 31 varieties was started, and about three-fourths of an acre set to trees and shrubs sent out by the college. The chief objects of the Fort Hays branch are the testing of plants and methods of culture with special reference to the needs of regions having deficient rainfall. In large part these experiments are expected to be upon a rather extensive scale, but performed with careful attention to all details, so as to yield results of scientific accuracy. The cooperative experiments of the station with this Department in the testing and breeding of cereals and in range improvement and forage-plant investigations will be conducted largely at the Fort Hays branch. Few of the buildings on the reservation could be used when repaired.

INDIANA STATION.—H. A. Huston, director of the station, has resigned to accept a position with the German Kali Works, in charge of their new branch office to be opened at St. Louis, Mo. This branch will be run as a part of the propaganda and will be purely educational. The territory covered by the St. Louis office will extend from eastern Ohio to Colorado and from Arkansas to Minnesota. Professor Huston will take up his new duties in April next.

IOWA COLLEGE AND STATION.—At a recent meeting of the trustees it was decided to devote the one-fifth mill tax levy granted by the last legislature for building purposes to the erection of the following buildings in the near future: A fire-proof addition to Agricultural Hall, 60 by 100 ft., for the use of the departments of agronomy and farm mechanics, greenhouses for agronomy and horticulture, and a two-story judging pavilion for agronomy and animal husbandry 60 ft. in diameter, to cost \$50,000; a central building for administration and general science purposes, to cost \$225,000; a new agricultural building, to cost \$200,000; and a central heating plant, to cost \$60,000. The erection of the buildings will be taken up in the order named. The addition to Agricultural Hall and the other buildings for the agricultural department will be taken up first, and will be completed by the opening of the next college year. The new main building, which takes the place of the one destroyed by fire, the new agricultural building, and the central heating plant will be erected as soon as the income from the tax levy permits. The new experiment station barn has been completed.

KENTUCKY STATION.—O. M. Shedd, a graduate of the Kentucky Agricultural College, has been made assistant chemist, to succeed L. O. Beatty; and E. P. Taylor, of the Colorado Agricultural College, has been appointed assistant entomologist and botanist, to succeed T. L. Richmond. The board of trustees at the recent semi-annual meeting authorized the erection of a new building, to be devoted exclusively to the station, and costing \$20,000. This will be erected on a parcel of ground recently purchased for \$4,000, and lying between the college campus and the station farm. The building will contain the offices of the different divisions of the station and their laboratories.

MINNESOTA STATION.—Beyer Aune, a graduate of the University of Minnesota, has been appointed foreman of the station farm.

NEBRASKA UNIVERSITY AND STATION.—A. T. Wiancko, instructor in agriculture in the university and assistant agriculturist of the station, resigned January 1 to go to Purdue University, where he will be connected with the instruction in agriculture, and will have charge of the field experiments of the Indiana Station.

CORNELL UNIVERSITY AND STATION.—The announcement is made that G. C. Caldwell has retired from active service, in accordance with the recent regulations of the trustees permitting professors to retire with pension. Professor Caldwell has been at the head of the chemical department of the university since 1868, and chemist of the station since its establishment. John W. Gilmore, B. S. A., has entered upon his duties as agriculturist of the station. Mr. Gilmore has recently returned from the Philippine Islands, where he was connected with agricultural work, and previous to that spent a year in Hawaii and two years in China engaged in teaching agriculture.

OHIO STATION.—At a recent meeting of the board of control of the station it was decided, in view of the great increase in the work and responsibilities of the agricultural department, to divide that department into the two administrative departments of agriculture and animal husbandry, and C. G. Williams, of Gustavus, Ohio, was appointed chief of the agricultural department and superintendent of the farm. Mr. Williams is a successful and progressive young farmer who is widely known over the State as an agricultural writer and a farmers' institute speaker. The appointment of a chief of the department of animal husbandry will be made at a later date.

RHODE ISLAND COLLEGE AND STATION.—Kenyon L. Butterfield has been elected president of the college and will enter upon his duties about April first. Mr. Butterfield was for several years superintendent of farmers' institutes in Michigan and is at present instructor in rural sociology in the University of Michigan, where he has been taking post-graduate work. T. G. Mathewson, of East Greenwich, has been appointed president of the board of managers to succeed H. L. Greene, resigned. L. P. Sprague, assistant horticulturist of the station, has resigned, and A. E. Stene, of Cornell University, has been appointed to succeed him.

SOUTH CAROLINA STATION.—A new barn for the station has recently been completed, and registered representatives of the beef and milk strains or breeds are being placed in it.

VERMONT STATION.—The general assembly, recently adjourned, has replaced the fertilizer and feeding stuffs inspection laws, passed respectively in 1888 and 1898, with new enactments. A brand tax has been substituted for a blanket license as a means of raising revenue for the enforcement of the fertilizer law, and a small appropriation has been voted the station for use in feeding stuffs inspection, thus doing away with the cumbersome and unsatisfactory tag tax system hitherto in vogue. The fertilizer law has been drawn in substantial conformity with the recommendations contained in the report of the committees on fertilizer legislation of the Association of American Agricultural Colleges and Experiment Stations and of the Association of Official Agricultural Chemists. A joint resolution was passed requesting the station to investigate the seed trade of the State, and to report to the next general assembly such findings and recommendations as are deemed wise and will contribute to the enhanced purity of grass and similar seeds.

WISCONSIN UNIVERSITY AND STATION.—T. F. McConnell, instructor in animal husbandry in the college of agriculture and assistant in the station, has been elected to the chair of animal husbandry in the Arizona University and Station.

U. S. DEPARTMENT OF AGRICULTURE.—Another building for the use of the Department has been erected by private enterprise. The new building is to accommodate the botanical work of the Bureau of Plant Industry, and is located on Twelfth street near the Department grounds. It is 85 by 40 ft. and 3 stories in height, with a large basement. The building has about 35 rooms above the basement, most of them of good size and well lighted. The basement will contain 4 large workrooms, 2 of these to be used for seed germination, and 2 as laboratories for investigations of drugs and medicinal plants and of poisonous plants, respectively. The first two floors will be given up to office and laboratory rooms for the pure seed investigations, drugs and medicinal plants, and poisonous plants; and the third floor will accommodate the cereal investigations, the tropical agricultural work, and the fiber plant investigations, and will contain a general photographic room and 2 dark rooms. The building was ready for occupation January 1. It serves to bring together the work in botanical lines which heretofore has been quite widely scattered.

SOCIETY OF OFFICIAL HORTICULTURAL INSPECTORS.—The second annual meeting of this society was held at Atlanta, Ga., October 6, 7, and 8, on the occasion of the convention of the Association of American Agricultural Colleges and Experiment Stations. Representatives were present from Florida, Georgia, Illinois, Massachusetts, New Jersey, New York, Pennsylvania, South Carolina, and Virginia. The sessions were presided over by S. A. Forbes, of Illinois, and W. M. Scott, of Georgia, acted as secretary. We are indebted to the courtesy of the latter for this account of the meeting. The proceedings took the form of discussions of topics suggested in a preliminary programme, rather than the presentation of set papers. At the conclusion of the discussion of each topic the views of the delegates on that point were recorded in a resolution offered by some member.

Upon the first topic, Interstate Comity with Respect to the Certification of Nurseries, the unanimous opinion of the delegates was to the effect that the examining

or certifying officer of each State accept at its face value the statements made in certificates duly granted under the laws of other States, so far as the laws of his own State admit, unless information at hand creates a reasonable doubt as to the regularity of the certificate or its application.

The discussion of the second topic, Exchange of Communications with Reference to Receipt of Diseased Nursery Stock Originating in Other States, was brief, as all present appeared to be of the same mind, viz, "that the inspectors of the several States should freely and frankly exchange communications with regard to nursery infestation, and that each should notify every other of such cases of infestation and attempts at evasion of the laws as might from time to time come to his notice."

The third topic related to Interstate Cooperation for the Control of Horticultural Pests whose Area of Distribution Extends Across State Lines. In the discussion several cases were cited in which it was shown that cooperation was necessary to produce the desired results, and this view was expressed in the resolution adopted, which gave the preference in the treatment of any particular pest to such cases.

Upon the question, Is it Desirable that Nurserymen Should Pay Any Part or All of the Expenses of Nursery Inspection Required by Law, Either Direct or as a Fee for a Certificate? considerable difference of opinion was expressed, some holding that there should be no fees; others that the nurserymen should pay small fees, as in the case of fertilizers, etc.; others that they should take out a license at a small fee, as a matter of record for the inspector. The resolution adopted, however, was to the effect that the nurserymen should not be required to pay the expense of the ordinary inspection of nursery stock. On the related topic, Is it Desirable that the Entire Cost of Insecticide or Fungicide Measures Required by Law Should be Borne by the Owner of the Affected Property? the consensus of opinion was that the State should not bear the cost of the treatment of private premises, but that the entire cost should be borne by the owner.

Various inspectors reported upon nursery pests in their respective States whose continued presence will prevent the certification of a nursery. Mr. Smith's practice in New Jersey was to withhold certificate from nurserymen whose premises were found infested with San José scale, at least until all infestation was eliminated; stock actually infested with black knot was not certified; yellows could not be detected on nursery stock and was hardly considered as a factor in the inspection; crown gall was inspected for, so far as possible, after the stock was dug, and visibly diseased plants discarded; stock badly infested with woolly aphis was destroyed; the occurrence of *Aspidiotus ancyllus*, *A. forbesi*, and *Chionaspis furfurus* would not debar the stock; the occurrence of any scale insect on imported stock would prevent certification, and the presence of *Diaspis pyricola* especially would act as a bar.

Mr. Fernald reported that in Massachusetts no certificate would be granted so long as the San José scale, *Diaspis pentagona*, *Aspidiotus ostryeiformis*, gypsy moth, brown-tail moth, yellows, rosette, or black knot was found infesting the stock. Crown gall, he stated, had not so far been found in Massachusetts.

Mr. Gossard reported that it was his practice in Florida to withhold certificate from the owner of premises infested with San José scale until the proper steps had been taken to get rid of the pest by fumigation or otherwise. *Diaspis pentagona* occurred in the State, but so far had not been found in the nurseries. Citrus plants were commonly infested with various scale insects, but no definite action had yet been taken with respect to such cases. White-fly was so generally distributed as to render restrictive measures against it impractical, but treatment was recommended. In cases of crown gall the owners were instructed to destroy all affected plants, and root-knot infestation was also rejected.

Mr. Hamilton stated that the prevailing rule in Pennsylvania was to grant a certificate when the nursery was found apparently free from San José scale, and to withhold the certificate when this pest occurred. Mr. Butz, of the same State,

explained further that in cases of crown gall, woolly aphis, and some other of the more injurious pests, the nurserymen were requested to discard badly affected stock.

Mr. Burgess reported that in Ohio the presence in a nursery of the San José scale, black knot, or peach yellows was sufficient ground for withholding certificate, and that plants infested with woolly aphis or affected with crown gall were caused to be destroyed. He stated that the oyster-shell bark louse was doing considerable damage in Ohio, and so far as practical its dissemination on nursery stock was prevented.

Mr. Phillips reported that the practice in Virginia was to withhold certificate from nurseries in which San José scale, black knot, or peach yellows was found until the trouble was effectually eliminated. Peach yellows had not so far been found in the nurseries, but diseased orchard trees in the neighborhood of a nursery sometimes occurred, and these were destroyed before a certificate was granted. The same was true of black knot. He stated further that severe cases of crown gall, woolly aphis, and pear blight were not admitted under certificate. Plants actually showing the presence of such pests were discarded.

Mr. Forbes required the Illinois inspectors to send in a statement of every pest found in the nursery, and before a certificate was granted he required the elimination of the San José scale and black knot. Precautions were taken to avoid sending out borers, woolly aphis, crown gall, and pear blight. Plants infested with woolly aphis to the extent of causing warty formations on the roots were discarded, and so also were plants visibly affected with crown gall. Noticeable infestation of the scurfy scale and bad cases of oyster-shell bark louse were rejected.

Mr. Scott stated that in Georgia the presence of the San José scale, *Diaspis pentagona*, black knot, or rosette would prevent the certification of a nursery; that stock seriously affected with crown gall, root knot, or woolly aphis was not allowed to be sent out under certificate; and that stock infested with the cherry scale, scurfy scale, or oyster-shell scale was caused to be properly treated before it was distributed. It had been his practice in suspicious cases to have the stock inspected on the heeling-in grounds for crown gall, woolly aphis, and scale insects.

Observers differed in regard to the prevalence of crown gall. This was reported as confined to the apple in Illinois and Virginia, to the peach in New Jersey and Florida, and equally common on the peach and apple in Georgia.

Mr. Engle, of Pennsylvania, called attention to the black peach aphis, which in his opinion all inspectors should rule against.

A motion was adopted calling for the appointment of a committee of three, including the chairman, to compare all existing laws concerning the control of insects and diseases in the nursery or orchard, suggest points to be covered in State legislation, and formulate suggestively uniform State and Federal legislation to regulate nursery inspection, interstate traffic, and orchard control, this committee to report at the next meeting.

With reference to the procedure taken in cases of nursery infestation with scale or other dangerous pests, Mr. Scott stated that the Georgia law prohibited the certification of a nursery when any portion of it was found infested, and that he had disposed of such cases according to the individuality of the nurseryman, as well as the circumstances attending the case, in the following manner: Case 1.—A portion of a large nursery was found infested with San José scale, and as agreed to by the owner its customers were notified of the exact conditions, with assurance that the stock actually infested would be burned and the remainder fumigated under supervision. To the surprise of both the owner and himself not a single order was countermanded and practically the entire stock was disposed of at the customary prices. Case 2.—Upon the inspection of a certain nursery a single specimen of San José scale was found upon a plum leaf, and in spite of a most careful examination no further infestation could be found at that time. A second inspection at the heeling-in grounds revealed a slight infestation of a dozen or more trees, which were thrown

out. The owner would not agree to the notification of his customers as in case 1, and a certificate to cover the contents of each box was issued after a list was furnished of persons to whom the stock was intended to be shipped. Other cases were treated similarly. Case 3.—In this case the nursery was located in a section where practically all the orchards were infested and the fruit interest was sufficiently great to demand all the stock grown in this nursery. The certificate issued set forth the facts, viz, that San José scale was found in a portion of the nursery and that the proper steps had been taken to eliminate it. Under this certificate practically all the stock was disposed of at market prices.

In Pennsylvania Mr. Hamilton required under affidavit the attachment of a statement of fumigation to each shipment. In Florida Mr. Gossard required a thorough cleaning up by destruction of trees actually infested and the fumigation of the remainder. In Illinois Mr. Forbes did not require the fumigation of the entire stock when scale was found in an isolated portion of the nursery, unless the indications were that there had been a general spread of the scale. However, fumigation was required for the infested portions or for the entire stock when the infestation was general. In New Jersey Mr. Smith required the fumigation of the entire stock when scale was found in the nursery, but under no circumstances did he allow shipments of stock from infested nurseries to go outside the State. However, he did not restrict the sale of such stock within the State. In Ohio Mr. Burgess's method was to destroy all infested stock and require the fumigation of such as was dangerously near. In Massachusetts Mr. Fernald gave the owner the option of fumigation or destroying the infested stock, and in cases of general infestation a fumigation affidavit was required.

Following these statements, a resolution was adopted expressing the opinion of the meeting that nursery stock fumigated according to accepted requirements should be considered as satisfactory as stock sold under certificates of inspection only.

A paper by Mr. Smith relating to recent observations and experiments with insecticides for the San José scale, presented before the section on entomology of the general association, was discussed by the inspectors; and Mr. Fernald reported upon some recent experiments by him in Massachusetts, said to represent the most extensive work against the San José scale ever done in New England. The discussion was quite general and extended, and tended to show that the petroleum oils, whale-oil soap, and lime-sulphur-and-salt wash constitute the standard remedies for the San José scale in orchards.

The society decided to meet again next year in connection with the Association of American Agricultural Colleges and Experiment Stations. S. A. Forbes was reelected chairman, and J. B. Smith was elected to the new office of vice-chairman.

MISCELLANEOUS.—The Carnegie Institution has made a grant of \$5,000 to Prof. W. O. Atwater, of Wesleyan University, for investigations on the measurement of oxygen in connection with metabolism experiments. The attempt will be made to modify the workings of the respiration calorimeter so as to introduce known amounts of oxygen into the respiration chamber to replace that used by the subject, instead of supplying the same in a current of fresh air, as at present. These investigations will be in the direction of a further refinement of the methods for studying the metabolism of nutrients in man, and are made desirable by the present status of the study which has been in progress at Middletown, in cooperation with this Department, for several years past. The determination of the oxygen balance will enable the calculation of the respiratory quotient, and will furnish much more accurate data for determining the net value to the body and the replacing power of nutrients from different sources.

The School of Practical Agriculture, recently located at Briarcliff Manor, N. Y., has moved to its new location at Poughkeepsie. No buildings have yet been erected, but two houses in the city have been rented and for the present the school will be quartered in these. As soon as funds are obtained to warrant the expenditure, a main

building and laboratories will be built at the farm which has been acquired outside the city. This school, which has been popularly referred to as the Briarcliff School, will hereafter be known as the School of Practical Agriculture at Poughkeepsie.

The death is announced of Dr. T. R. Segelcke, professor of dairying in the Royal Veterinary and Agricultural College at Copenhagen. Professor Segelcke was one of the very first to take up the systematizing of butter and cheese making as based upon the observance of scientific principles of management, and has been generally recognized as the father of modern dairying in Scandinavia. For many years he carried on a propaganda for the improvement of dairy practice among the farmers in Denmark, and found an able second in Professor Fjord, who took up the experimental side. He was appointed instructor in dairying at the Royal Agricultural College in the early sixties, and in 1874 was made professor of that branch. He is said to have been the first professor of dairying appointed to any institution in the world. The number of students in the institution grew from 2 in 1864 to 189 in 1877. Professor Segelcke's lectures were very popular, and have been frequented by nearly all the teachers of dairying and the leading dairy specialists in the Scandinavian countries for 25 years past. He also held courses of two to three months in practical dairying at a large number of first-class creameries in different parts of Denmark. His popularity was shown on the occasion of the celebration of his seventieth birthday by his students last year. Of late years he had confined himself more especially to his lectures at the college, but remained at the head of the commission charged with carrying out the regulations of the oleomargarine laws.

The Chemical Physiological Experiment Station for Wine and Fruit Growing at Klosterneuburg, Austria, has been discontinued and the control work of the station united with that of the Agricultural Chemical Experiment Station at Vienna, under Dr. F. W. Dafert. The viticultural division of the Vienna Station has also taken charge of all work in that line at the Klosterneuburg Station, except the preparation of yeast cultures for wine making, which in future will be in charge of the Higher School for Wine and Fruit Culture at Klosterneuburg.

We quote the following from *Nature*: The committee of the class including agricultural practice and agricultural statistics at the Paris Exhibition of 1900 has decided to make a grant of 2,400 francs to the agricultural section of the Paris Society for the Encouragement of National Industries, to be employed in agricultural research in such a manner as the committee of the society determines. In his letter to the president of the society, M. Tisserand, on behalf of the exhibition committee, expresses satisfaction that such a grant is possible as the outcome of the work of the section of the exhibition represented by him.

A recent number of *Chronique agricole du canton de Vaud* gives an account of a very enthusiastic celebration of the seventy-fifth anniversary of the birth of Samuel Bieler, and of the twenty-fifth anniversary of his appointment as director of the Cantonal School of Agriculture. Representatives of many important agricultural societies and institutions of Switzerland participated. Professor Bieler, by public addresses, lectures, publications, and activity in various societies, has exerted a considerable influence on the progress of agriculture in Switzerland, largely by popularizing science relating to agriculture and making it available for the practical agriculturist.

The first number of *The Australian Gardener* recently reached this Office. It is a monthly journal of 16 to 18 pages and devoted mainly to floriculture. It also contains information of a practical character upon vegetable and fruit growing, and is designed for professional, practical, and amateur gardeners in Australia, New Zealand, Tasmania, and South Africa.

A school for tanning industry, the first to be established in Italy, was opened at Turin in December. The school was founded by the local association for the tanning industry.

EXPERIMENT STATION RECORD.

VOL. XIV.

FEBRUARY, 1903.

No. 6.

An interesting feature of the Washington meeting of the American Association for the Advancement of Science was a discussion, by six men selected to represent different branches of science, of the question: How Can Endowments be Used Most Effectually for Scientific Research? The occasion of this was a joint session of the biological societies with the American Society of Naturalists.

While various phases of this question were covered by the different speakers, one point quite prominently emphasized by nearly all was the prime importance of the *man*. This single factor overshadows all others in research—the theme, the equipment, the surroundings, and other material resources. Large amounts of money, magnificent laboratories, expensive and elaborate equipment do not insure research of high order, and only to a limited extent will they promote it. Men with well-developed investigating instincts are the great prerequisite. Such men will rise above their surroundings, and will accomplish results in spite of conditions which are not ideal. They will not allow a lack of the latest facilities or the best arrangement of their time to deter them from the pursuit of knowledge. This is the genius of the research worker, that his zeal and devotion and his inspiration serve to offset, if necessary, unfavorable conditions which to another would be deterrent.

Special natural traits and qualifications are required for the successful research worker. Considerable of our research work, as one speaker stated, is carried on because research is more or less of a fad—the thing for the student to do; and this often leads men and women into research work who are not suited to it by nature or capable of rising above a comparatively low level in that line of activity.

The conditions prevalent in this country, with its many opportunities and distracting influences, do not favor the highest development of the qualities necessary in the research worker. There is a lack of incentive—the opportunity for a career which other lines hold out. The position of the man of science who devotes himself to research is

not assured as it is in Europe. Research work is comparatively new in our universities as yet. Men have been commonly selected for teaching mainly because of their ability as instructors, rather than as investigators in science. The commercial field holds out such financial inducements that it attracts many of the most brilliant men, and unfortunately it is not always the brightest men who take up advanced work in our universities. These influences, together with an impatience for recognition and a restlessness which often leads to superficial work, militate against the highest development of research in this country. The remedy for this is the spread of education and a more general appreciation and understanding of research.

Prof. Asaph Hall, the president of the association, expressed sentiments in line with these thoughts in his retiring address. He said: "The great steps of progress in science have come from the efforts of individuals. Schools and universities help forward knowledge by giving to many students opportunities to learn the present conditions, and from them some genius like Lagrange or Gauss may come forth to solve hard questions and to break the paths for future progress. This is about all the schools can do. We need a body of men who can give their lives to quiet and continuous study."

This need is not confined to any particular branch of science. The genius and acumen required for investigation find a no mean field for the exercise of their full faculties in the realm of applied and economic science. Special qualifications and training seem necessary to applying the results of investigation in pure science to practical everyday life. The high plane of this work and its value to mankind were well expressed in Dr. Jordan's address before the Society for the Promotion of Agricultural Science, which will be printed in the next number.

The advantages of institutions designed especially for research were emphasized by several of the speakers in this discussion; and this, it may be noted, is one of the greatest initial advantages of the agricultural experiment stations.

With reference to cooperation in research it was held, at least by one of the speakers, to be a mistake to strive too much after coordination. Cooperation, it was pointed out, often means subordination, which is usually stifling in its effects; and the best plan was thought to be for each institution to go on in its own way in research, rather independently, and work out its own plan, whether it lead to success or failure.

While it is not unusual to encounter this feeling, or something akin to it, among investigators, the growing complexity of science and the increase in specialization seem to make a certain amount of cooperation very desirable. This is especially the case in investigating problems in applied science. There is greater need than ever for a considerable

number of men, representing different branches of science, to collaborate in their undertakings and thus to strengthen the work of both. Some of the most successful features of our experiment station work illustrate this quite forcibly. Nearly every experiment station furnishes some good examples. We have only to be reminded of some of these to see that cooperation within the station has not necessarily meant subordination. We have come to regard a union of two or more departments as extremely advantageous in many lines of station work, from the standpoint of the individual workers as well as that of the product as a whole. And one of the greatest services of the successful station directors has been to bring about a union of effort among members of the station staff, and to so coordinate and direct the work of different departments that the energies will not be scattered or the work too disconnected and fragmentary.

The name of Pierre Paul Dehérain is familiar to all readers of this journal. For years he has been one of the leading spirits in agricultural investigation in France, and is widely known through his writings and his works. His death occurred in Paris December 7, 1902, at the age of seventy-two.

Dehérain's earlier years were occupied in teaching chemistry in the Central School of Agriculture, and in 1865 he was appointed professor of chemistry in the Agricultural School at Grignon. In 1881 he was made titular professor of vegetable physiology in the Museum of Natural History at Paris, an honor which he highly prized, and in 1887 he was elected a member of the French Academy of Science in the vacancy caused by the death of the famous Boussingault.

During his long connection with the National School of Agriculture at Grignon and the station at that place, of which he was director, his time was devoted principally to investigation of problems in plant nutrition and growth, the culture of various special crops, the fermentation of manure, and soil problems. In the latter connection his studies on nitrification, the loss of nitrogen from the soil, and the value of cover crops as an aid to improvement, were conspicuous. In 1875 he established his *Annales agronomiques*, which he continued to edit until the close of his life. His publications in this journal and his *Cours de chimie agricole* (1872), *Traite de chimie agricole* (1892, recently revised), and *Les engrais, les ferments de la terre* (1895), may be mentioned as among his most important writings on agricultural chemistry.

Although Dehérain's name is not associated with any great discovery, he made very important contributions to the methods of investigation, notably in pot and plat work, and to the problems of plant nutrition and of nitrification. His work was conducted with such care and so thoroughly weighed and digested before publication that it inspired a high degree of confidence. His name will occupy a high place in the annals of agricultural chemistry and plant physiology.

AGRICULTURAL SCIENCE AT THE AMERICAN ASSOCIATION MEETING.

Although the American Association for the Advancement of Science contains no section for agriculture or agricultural science, it is doubtful if any other organization contributes so large a number of papers bearing directly and indirectly on that subject. The meeting in Washington during convocation week was especially rich in this respect. It brought together over 1,350 scientific men who are members of the association or some of its numerous affiliated societies, among them many who are active workers in the special fields of agriculture. It furnished the occasion for presenting the latest progress in the sciences on which agriculture is based, and held much of interest to every agricultural investigator.

This fact emphasizes the intimate relation of the work of the experiment stations to the work of this great association as a whole, and to the progress of science in general. From present indications the winter meetings of the American Association and its affiliated societies may be regarded as a scientific center for the presentation of technical papers in agricultural science, and as such of the greatest importance to the experiment station worker. The scope of the association is sufficiently broad to take in all lines of agricultural investigation; and the inspiration gathered from coming in contact with so large a body of men whose lives and interests are allied with the advancement of science in various directions, is far reaching and can not fail to be most helpful. This is especially true now that the economic and applied phases of science form so conspicuous a feature of the meetings.

It has been thought a matter of interest to bring together, as far as possible, those papers which related quite directly to agricultural science. No such grouping is otherwise provided for, and as they are so widely scattered through the proceedings of at least twelve different sections and societies many of them are likely to be lost sight of. The selection of these papers from the scores which are of undoubted interest to agriculture in the broader sense is often somewhat embarrassing, but the scope of this journal has been taken as a general guide. The aim has been to group the papers by subjects, regardless of the section or society before which they were presented. No attempt is made to give a complete report for any of these bodies, as that is done through other agencies.

AGRICULTURAL CHEMISTRY.

A liberal proportion of the papers presented before the section of chemistry of the American Association and the American Chemical Society, which held joint meetings, were in the field of agricultural chemistry or had a quite direct bearing on agricultural investigation.

The address of the vice-president of the section of chemistry, H. A. Weber, was on the subject of Incomplete Observation. In this he reviewed in a general way the changes in our theories on a number of subjects, and gave especial attention to the investigation of the assimilation of nitrogen by plants. Beginning with the work of Boussingault, which for a long time was the basis of the belief that plants could not assimilate nitrogen, he traced the attempt to overthrow this theory, closing with the classic investigations of Hellriegel, which established beyond further doubt the ability of legumes to draw nitrogen from the air. From the conflicting evidence of investigations on this important topic during a period of more than forty years, the speaker drew some deductions as to the danger of inaccurate and incomplete observation, and the way in which this may temporarily hinder the progress of science.

H. W. Wiley described the nature of the work of the Bureau of Chemistry of this Department, and explained the present organization of the Bureau. There are now 8 laboratories, each with a quite well-defined field of work, i. e., foods, sugar, dairy products, fertilizers, soil analysis, road materials, insecticides and agricultural waters, and dendro-chemical studies. Some special features of the work of each of these laboratories were briefly reported, and mention was made of some of the more comprehensive undertakings of the Bureau, such as the study of the effect of environment on the chemical composition of crops, notably the sugar beet and the gluten content of wheat; the comparative study carried on with the experiment stations on the fertilizer requirements of plants, and the means of determining these by chemical analysis; and the investigation of the effect of food preservatives on the metabolism and digestive functions, which is now in progress.

E. A. de Schweinitz described the work of the biochemic laboratory in the Bureau of Animal Industry. He explained that biochemistry has now become recognized as a quite distinct branch of chemical science, a number of professorships having been established, and a journal for biochemistry inaugurated in Europe. In a general way the biochemic laboratory studies the character and properties of toxic and nontoxic substances produced by bacteria within and without the body, and the relation of these substances to disease and its prevention. Dr. de Schweinitz described the biochemic work on tuberculosis, which has had for its aim a study of the relation of the germs from

man and from animals in their growth on artificial media, determining the production of fat, ash, and phosphoric acid by them. This has been an aid in showing the intimate relation of tubercle bacilli from human and bovine subjects, and has led to the improvement of media for the isolation of tubercle bacilli in animal tissue. It has been found that a good tuberculin can be prepared from nondisease-producing bacilli attenuated by growth on acid media. Reference was made to the work with mallein for use in detecting and treating glanders; a study of the effect of germicides on enzymes, and also of the products of bacterial growth; and the more recent studies which have been undertaken on dairy bacteria and the effect of their products on dairy products.

In a paper on *The Chemical Work of the Bureau of Soils* F. K. Cameron referred briefly to the various lines of work of the laboratory of soil chemistry of that Bureau. He mentioned especially that relating to the devising of methods of examining soils in the laboratory and in the field, and studies of soil solutions with reference to formation and distribution of alkali salts and to plant nutrition. Work of this character has been noted from publications of the Bureau (*E. S. R.*, 13, pp. 428, 918, 927).

A paper on *The Composition of Fresh and Canned Pineapples*, by L. S. Munson and L. M. Tolman, reported data which have been gathered with a view to determining whether the fruit has been preserved with or without the addition of cane sugar. Thirty-two samples of fresh pineapples from Florida, Cuba, Bahamas, and Porto Rico ranged in total solids from 10.78 to 18.86 and averaged 14.17 per cent, and in total sugars from 7.88 to 14.74 and averaged 11.50 per cent. Ten samples of canned pineapples from Singapore, put up in their natural juice without the addition of cane sugar, averaged 13.39 per cent of total solids and 11.56 per cent of sugar, while 6 samples from the same source, canned with the addition of cane sugar, averaged 18.17 per cent of total solids and 16.78 per cent of sugar. The averages of 31 samples of canned pineapples from appraisers' stores, New York City, obtained from Singapore and Straits Settlements, were 21.04 per cent of solids and 17.67 per cent of sugar, and of 11 samples from the Bahamas 14.13 and 10.73 per cent, respectively. The same authors, with E. M. Chace, reported upon *The Chemical Composition of Some Tropical Fruits and Fruit Products*. The fruits analyzed were gathered in Cuba. They included oranges, grape fruit, limes, bananas, tamarinds, guavas, mangoes, pineapples, sweet sop, sour sop, cherimoyer, nispero, mammee, hicaco, and maranon (cashew). Various preserves made from a number of these fruits were also described. Some deductions were drawn with reference to the high content of solids and sugar in these fruits, although the relation between the

solids and sugar was said to be about the same as in northern grown fruits.

The Iodin Absorption of Oils, Comparison of Methods, was the title of a paper by L. M. Tolman and L. S. Munson. The objections to the Hübl method, as pointed out, are the liability of the solution to change with age affecting the result of titration, and the length of time employed, in which there is a considerable difference in the practice among analysts. Comparison was made of the Hübl, Wijs, and Hanus methods on butter, oleo, cocoanut, and a variety of other oils. The three methods were found comparative only on oils with low absorption, like butter and oleo. A special investigation of olive oils of known purity showed both the Wijs and Hanus methods to be satisfactory; but the authors have adopted the Hanus method, as the solution is simpler to prepare, and propose it as a substitute for the Hübl method, with which it agrees well on all oils except on drying oils.

A. H. Gill discussed the question of the occurrence of cholesterol in corn oil, which has been reported by Hoppe-Seyler and by C. G. Hopkins. The matter is of interest, as corn oil is one of the very few vegetable oils from which cholesterol has been reported. The speaker pronounced the melting point reported by Hopkins as too low for cholesterol, and the color reaction as unreliable. He prepared the substance and obtained about 0.22 per cent. This he identified as phytosterol, instead of cholesterol. The substance agrees with that obtained from wheat by others, and is thought beyond doubt to be phytosterol.

H. E. Alvord presented (before the Society for the Promotion of Agricultural Science) the results of determinations of the water content of 800 samples of butter from 400 creameries located in 18 States. The collection was considered representative of the creamery product of the United States. The butter was made during the period from May to September. The water content for the period covered varied from 7.20 to 17.62 per cent and averaged 11.78 per cent. Of the total number of samples seven-eighths showed between 10 and 14 per cent of water and over one-half between 11 and 13 per cent. The percentages for the different months were as follows: May, 11.81; June, 11.91; August, 11.79, and September, 11.59. It was pointed out that the water content can not be judged by appearance.

C. A. Crampton, of the Bureau of Internal Revenue, reported upon The Composition of Renovated or Process Butter. The speaker described the methods ordinarily practiced in making renovated butter, the origin of the stock, etc. The product does not vary much from ordinary butter in composition, as shown by analyses of samples collected officially from the principal manufacturers of renovated but-

ter in the United States. The average was as follows: Water (by direct determination), 14.44 per cent; fat, 82.05; curd, 1.47, and ash, 2.85; Reichert-Meissl number 29.15, refractive index 1.4608, Crismer value 49.05, Valenta value 41.6, acidity 6.57, and iodine number 36.78. The usual tests applied for renovated butter are polarized light, boiling in open vessels, and the Waterhouse tests, but each of these tests failed in one or more cases on the above samples. A study was made of the changes in the fat during the manufacture of renovated butter to determine whether any change was produced in the oil which might serve as a means of detection. There was no decided change in the character of the fat after blowing or renovating. The greatest difference was found in the Reichert-Meissl value, but this was not regular. The speaker concluded that for the present physical tests must be relied upon for detecting renovated butter.

The same author also presented a paper on the Composition of Spirits Produced from Grain and the Changes Undergone by the Same when Stored in Wooden Packages, the work reported being a study which has been in progress for a number of years, with reference to the fixing of standards and the detection of added coloring matters.

In a paper on Solubility Curves for Magnesium Carbonate in Aqueous Solutions of Sodium Chlorid, Sodium Sulphate, and Sodium Carbonate, F. K. Cameron and Atherton Seidell reported a continuation of their studies of the theory of solution as applied to soils, especially the formation and transportation of alkali in soils (*E. S. R.*, 13, p. 927). These have given valuable results in pointing out a satisfactory chemical classification of alkali, giving a clearer insight into alkali phenomena, and explaining the effects of certain methods of treatment of soils.

O. Schreiner described A Method for the Colorimetric Determination of Phosphates and Silicates when Both are Present, which he claimed is especially applicable to waters, soil solutions, and plant solutions. The method is based upon the comparison of the coloration produced when ammonium molybdate and nitric acid are added to unknown solutions containing phosphates and silicates, with that produced when standard solutions are so treated. The method of procedure consists in adding to one of two equal portions of the solution to be tested the ammonium molybdate and nitric acid simultaneously, to the other ammonium molybdate first and the nitric acid one-half hour afterwards. It is claimed that the coloration produced in the second case by the silicates which may be present is just about one-half that produced in the first case. From this equations are derived which furnish a ready means of calculating the relative proportions of phosphates and silicates present.

In a paper by J. H. Long on The Relation of the Specific Gravity of Urine to the Solids Present, it was pointed out that the important thing in urine analysis is not the total solids but the solids of metabo-

lism, i. e., the total solids less the salt, which can be easily determined by estimating the salt. The author gave the factor or coefficient which he has worked out.

A paper by A. S. Loevenhart on Some Observations on the Rennin Coagulation of Milk, which was presented before the American Physiological Society, may be mentioned here. It was explained that in the rennin coagulation of milk there is a stage when the milk may yield a heat coagulum before there is any apparent change in the consistency of the milk. The interval between this metacasein stage and the spontaneous coagulation varies inversely with the amount of rennin present; it may be so transient as to be imperceptible, or it may be indefinitely prolonged by any agency which partially fixes the calcium, as boiling, adding a little ammonium oxalate, etc. Large amounts of ammonium oxalate entirely prevent any heat coagulation at this stage, indicating that soluble calcium salts are necessary for the metacasein reaction. If the rennin be destroyed by heat at that stage, a coagulum will be produced by the addition of calcium chlorid, indicating that the caseinogen has been largely transformed into paracasein. Fresh milk can not precipitate paracasein solutions nor can it prevent the precipitation of paracasein by calcium chlorid. These facts led the author to conclude that the calcium salts in milk are altered in some way during the action of the rennin, and by virtue of this become capable of precipitating paracasein. It was suggested as most probable that the calcium salts of the milk are very loosely combined with some constituent of the milk, and that these compounds are dissociated during the action of the rennin.

BOTANY.

The botanical papers of agricultural interest were about equally divided between the section of botany of the Association, the Botanical Society of America, and the Society of Plant Morphology and Physiology. Isolated papers on botanical subjects were also read before other sections and societies and are here included. There were many others of general interest to botanists but not of sufficient direct bearing on agricultural science to be included in this review.

In his vice-presidential address before the section of botany, D. H. Campbell took the subject of the Origin of Terrestrial Plants. The various factors influencing the development of terrestrial plants were stated to be food, water, and various modifications of the reproductive plant organs. Of these factors the speaker held that water was one of the primary factors in determining whether a plant should be aquatic or terrestrial. The progressive development of plants from aquatic through amphibious to terrestrial habits was traced.

J. C. Arthur, retiring president of the Botanical Society of America, delivered an address on Problems in the Study of Plant Rusts.

He reviewed the present knowledge of rusts, paying particular attention to the work of Eriksson as well as of a number of investigators who have studied heteroecious rusts. The probable number of species of rusts which are more or less definitely known was estimated at one thousand or more. Among the grass rusts no species attacks species of grasses of more than one tribe. Doubt was expressed as to the accuracy of the mycoplasma theory of Eriksson. In conclusion the possible lines of cytological investigations with the Uredineae were pointed out.

Before another section of the Association B. T. Galloway outlined the work of the Bureau of Plant Industry of this Department. Among the investigations in vegetable pathology only one was mentioned, that in selecting cotton resistant to the wilt, whereby the important sea-island cotton industry has been reestablished. Investigations in vegetable physiology were grouped under two heads: (1) Those relating to the food of plants, and (2) those relating to the improvement of plants. Under the first head mention was made of the efforts to increase the available nitrogen in the soil through the agency of nitrogen-collecting bacteria. The more general use of legumes has been promoted, and new legumes have been introduced, together with the micro-organisms necessary for their successful production. Among the investigations for the improvement of plants those mentioned as among the most important were in breeding and selection for special qualities, such as in wheat for immunity to rusts and other diseases, and in corn for increase of oil, starch, or nitrogen. The speaker also called attention to the trial shipments of fruit for the opening up of new markets and for the education of fruit growers in methods of shipping.

As was to be expected, the subject of plant breeding received much attention at the various meetings of the botanists, and it was evident that the matter was one of very live interest to a large contingent. The Society of Plant Morphology and Physiology had arranged for a discussion of Mendel's Law and its Bearings, to be led by L. H. Bailey and H. J. Webber. In this Professor Bailey took up the subject of mutations and variations, outlining de Vries's investigations and theories. Mutations were said to be fixed in their character from the time of their appearance, while variations are more or less progressive. Attention was called to the work of Mendel, which was highly complimented as being an important factor in putting aside the former idea that hybrids are largely due to chance, and showing that, to a certain extent at least, they are governed by certain fixed laws. The recent studies of Mendel, de Vries, Correns, and others were said to show most emphatically that in the studies of hybridism the old taxonomic idea of species must be abandoned. The practical benefit to be obtained from the recent investigations in hybridity, so far as the

plant breeder is concerned, will lie along the improvement of methods of investigation.

Mr. Webber discussed the unit character as opposed to species character. In this he held practically to the same view expressed by Professor Bailey that taxonomic species were without value in the consideration of hybridity. The speaker was inclined to believe that the study of the chromosomes would not offer an explanation as to the phenomena of descent. He illustrated some of the modifications and confirmations of Mendel's law as shown in his experiments with corn, cotton, and other plants.

Discussing these papers W. H. Brewer called attention to the experiments in the breeding of animals, and William Saunders pointed out exceptions to Mendel's law in the case of crosses of raspberry, barberry, etc. Before the Society for the Promotion of Agricultural Science, Dr. Saunders outlined some results of experiments in cross-fertilization conducted at the Canada Experimental Farms. The object sought in cereals was early-ripening sorts which were productive and of good quality. Red Fife wheat was crossed with early-ripening sorts from Russia and India. In this way crosses have been secured which are from 4 to 10 days earlier, and satisfactory in other respects. In experiments in crossing apples, 14 sorts have been secured which are considered satisfactory enough to be grown for general use.

In a paper before the section of botany, H. J. Webber gave an account of experiments conducted by himself and W. T. Swingle on the crossing of citrus fruits. The ordinary sweet orange has been crossed with the hardy deciduous *Citrus trifoliata*, and during the past season a few specimens fruited. Among the hybrids 2 were described which are believed to possess some merit, the plants being more tolerant to frost than the ordinary sweet orange. The fruits, however, are smaller and decidedly inferior to the sweet orange, although a considerable improvement over the fruit of the hardy orange. They are thin skinned, juicy, and nearly seedless, but very sour, the flavor resembling that of the lemon more than the orange. The trees are reported to be evergreen or semievergreen, and capable of withstanding a temperature of 8° F. without appreciable injury. From the seed of these hybrids it is expected that some better varieties may be obtained. The fruits of a cross of the pomelo and tangerine were also described, the fruit being nearly intermediate in size and color between the two.

A paper by Hugo de Vries, on atavistic variations in *Oenothera cruciata*, was read by H. C. Cowles. The author gave the results of his experiments, describing various mutations. In Europe there seems to be a quite common variation of this American plant, and a number of other forms were mentioned which were attributed either to mutations or crosses.

Among other physiological papers was one by K. Goebel, on Regeneration in Plants, read by D. T. MacDougal. In this paper an account was given of the regeneration in Bryophyllum, Begonia, and other plants in which various phenomena were shown by the repeated removal of vegetative shoots from leaf buds, etc. In many instances seedlings were shown to have the power of reproducing parts that had been lost through various causes. The theoretical consideration of the causes was noted. In the discussion which followed, T. H. Morgan combated the hypothesis of Goebel that regeneration is due to the presence of "formative stuffs" and of polarity.

The Early Root Development of Tree Seedlings, an Important Factor in their Local Distribution, was the subject of a paper by J. W. Tounney. The correlation between the early root development and the local distribution of seedlings was shown by means of a series of lantern slides. The seeds of about 150 species of trees have been planted and the seedlings examined to determine whether the root systems exert an influence on the distribution of the species. Hickory produces a strong, persistent tap root, and these species persist on account of these tap roots seeking crevices in rocks and penetrating the soil deeply, so that they can flourish in poor, rocky soils. On the other hand, oaks do not have such a persistent tap root but soon develop secondary roots, and on this account oaks in general require a more moist soil than hickories. The tap root of the beech develops strongly for a time, but in the course of a year a broad system of lateral roots is developed, the tap root being checked in its further growth. Similar root systems are found in the maple and red ash, and these trees require a rich soil for their best growth. The sugar maple develops lateral roots quite early, and in general trees which develop strong lateral root systems in their early stages are not adapted to growth on sterile soils. Attention is called to the fact that in desert regions all the shrubby plants develop long tap roots.

A. D. Selby described etiolated seedlings of the alligator pear (*Persea gratissima*). The etiolated and normal plants were of about the same height, but structurally, as well as in color, considerable differences were noted. In the etiolated seedling the leaves were strongly modified and greatly reduced in size, and considerable differences in stem structure were also noted.

W. F. Ganong pointed out that while most persons interested in botany accept the statement that stamens and pistils are sexual organs, it is denied by some of the newer morphologists, who hold that sexuality is confined to the gametophyte within the embryo sack and the pollen grain. The author showed that the older terminology is correct, and that pistils and stamens should be viewed as sexual organs.

The isolation of a hitherto unknown pigment found in the leaves of *Sarracenia purpurea* by W. J. Gies was reported. The same author

is said to have extracted a digestive fluid from the pitchers of *S. purpurea*, the ferment being an active digester of fibrin.

The rate of growth as affected by light and darkness was the subject of a paper by D. T. MacDougal, a very brief summary of which was presented. In substance the author reported that the average rate of growth is no less in the light than in darkness, nor does the average rate of elongation materially differ.

B. M. Duggar presented a paper on The Nutrition of Certain Edible Basidiomycetes, in which Brefeld's work was reviewed, as well as that published in Bulletin 16 of the Bureau of Plant Industry. The author has been successful in growing these fungi through several generations by the addition of basic salts, also when fragments of the fungus were added to the culture media. It was found in practice that bits of tissue instead of spores gave excellent results when grown in pure cultures. When the fungus is not an obligate parasite any basidiomycete may be grown in this way.

The same speaker described The Toxic Effects of Some Nutrient Salts on Certain Marine Algæ. The experiments on which this work is based were conducted at the Marine Zoological Laboratory, Naples, and at Woods Hole. Ordinary sea water is said to contain about 3.86 per cent of total salts. By varying the amount of the different salts it was possible to determine the toxic effect of different compounds. These were presented in gram-molecule solutions, and it is believed that the action is molecular rather than attributable to ions. The magnesium salts were found to be the least toxic of all, while the ammonium salts occupied a high position among the toxic elements.

The Decrease in Vitality of Grain by Age was the subject of a paper by William Saunders. Twelve samples of seeds grown in 1897 were stored in an office building at ordinary room temperatures, and subjected to germination tests each year from 1898 to 1902. The samples included 3 varieties of wheat, 3 of oats, 2 of barley, 2 of peas, and 1 of flax. The average percentages of germination for the five years were as follows: Wheat, 80, 82.3, 77.3, 37.3, and 15; oats, 90.2, 93, 78.2, 67, and 54; barley, 97, 91, 78.5, 36, and 19.5; peas, 94, 95, 88, 64, and 64; and flax, 81, 82, 75, 49, and 26. The results show that the seeds germinated as well the second year as the first, that a slight decrease in germination occurred during the third year, and a great decrease during the fourth year.

The Introduction of the Banana into Prehistoric America was discussed by O. F. Cook before the Anthropological Association.

H. C. Cowles traced the physical and ecological resemblances between the sand dune formations of Cape Cod and Lake Michigan. Certain peculiarities of the flora of each region were pointed out, the ocean side of Cape Cod not showing any zonal arrangement of plants. The conditions of Cape Cod are said to be less xerophytic than usually

supposed. The number of plants on Cape Cod is said to be much more abundant than on the dunes of Lake Michigan, while about 75 per cent of the species were common to each region.

In this connection mention may be made of a paper, not altogether botanical, by A. S. Hitchcock on the work done in the fixation of sand dunes in Europe. The matter was presented before the Society for the Promotion of Agricultural Science, and was based on a recent personal examination. The countries visited were Holland, Denmark, Prussia, and France. In some places work along this line has been carried on for 100 years, but the more successful methods have been employed only during the last 30 years. The objects sought are the protection of the land back of the sand and the utilization of the sand itself. Various methods, such as the use of some dead cover, stakes, and artificial dunes, have been employed for holding the sand in place until the desirable forest covering can be secured. Close to the sea a forest covering can not be established and the growth of sand grass or beach grass is encouraged. It was stated that in the United States efforts along this line are being made only on Cape Cod and to a less extent near San Francisco. W. Saunders described briefly the work being carried on at Sable Island, in which favorable results have been obtained in the introduction of *Pinus maritima*.

Several papers on plant diseases of various kinds and the organisms causing them were presented before the botanical or other bodies.

W. A. Kellerman discussed various suggestions and experiments regarding uredinous infection. The author worked with 17 forms of rusts, making about 80 experiments. A number of new aecidial forms have been discovered and were mentioned. The author described a simple cheap cover, consisting of a frame of wire netting covered with cheese cloth, which is well adapted to experimental purposes until transpiration becomes too great. At this time a galvanized-iron frame carrying glass sides and top is to be substituted. The speaker urged extreme care in avoiding accidental infections. In working out of season in the greenhouse he recommended that both host plant and fungus should be similarly treated as to heat, moisture, etc., as preliminary to infection experiments.

Following this paper J. C. Arthur gave an account of his Cultures of Uredineæ in 1902. These were mostly made on heteroecious rusts of grasses and sedges. Three hundred and fourteen cultures were made, of which 23 collections failed to give any germination. More than 100 hosts were used, and the successes and failures were enumerated. The necessity of field investigations as a preliminary to infection experiments was pointed out, and it was suggested that when a rust is found in the field the collector should carefully examine and report upon all the plants growing within a radius of about 10 feet of the host carrying the rust, as this might furnish hints as to the possible alternate hosts of the species.

A paper by L. R. Jones and L. P. Sprague, entitled Plum Blight Caused by the Pear Blight Organism, was read by L. R. Jones. The blight was confined to young plum twigs from which the pear blight organism (*Bacillus amylovorus*) was isolated. The inoculation of green pears with portions of the diseased plum twigs was found a very satisfactory method of investigation. Organisms isolated from both the plum and pear were grown in a series of artificial cultures and found to behave alike in every respect. Typical cases of pear blight were produced by inoculation with the bacillus obtained from plum twigs. The typical plum blight, however, was not secured by inoculation. The organism was believed to gain access to the young twigs by way of the axillary buds. If allowed to develop unhindered in plums, it was suggested that the organism may acquire increased virulence toward this host.

E. F. Smith called attention to a bacterial disease of Japanese plums in which both leaves and fruit are affected. The organism was found to enter through the stomata existing on the fruit and leaves. The disease was first reported from Michigan, and although under investigation for a number of years, a single organism has always been found present. In one orchard the fruit of four-fifths of the Hale plums were affected, and a second variety, Wickson, was attacked to a less extent. The organism, entering through the stomata of the fruit, develops abundantly, breaking down the tissues and producing peculiar diseased areas, which were described at considerable length. On the leaves the organism causes a shot-hole effect, the dead portions falling out. This organism has been isolated and cultivated, and inoculation experiments prove it to be the cause of the disease. It is described as *Pseudomonas pruni*, n. sp. In a second paper the author offered proof that *P. stewartii* is the cause of the sweet corn disease occurring on Long Island. This disease may be first recognized from the character of the inflorescence, the male spikes giving the first indication of disease. These take on a peculiar white color, followed later by the wilting of the corn, which is said to characterize the disease. The author isolated and cultivated the organism, and by means of inoculation has secured characteristic symptoms of the disease in at least 75 per cent of his infections.

L. R. Jones gave the results of studies of cytohydrolytic enzymes produced by the soft rot bacteria, *Bacillus carotovorus*. The enzyme was separated from the living organism by filtration, sterilizing by heating; by the use of phenol, thymol, or formalin, and by precipitation. Detailed studies were made with the enzyme secured, and practically no diastatic action was observed.

W. A. Orton, in a paper read before Section G, described a disease of mulberry fruit which is reported from Georgia, Alabama, and Mississippi. Often as much as 50 per cent of the fruit is affected. The symptoms are peculiarly enlarged portions of the aggregated

fruits. The disease is of fungus origin, and the point of attack seems to be the seeds, which are greatly enlarged. The fungus, which is closely allied to *Gloeosporium*, was described as a new genus, *Spermatomyces*, the species name *mori* being given to it.

H. von Schrenk presented a paper on the production of wart-like intumescences as a result of spraying with various fungicides. In the greenhouses at the Missouri Botanic Gardens in St. Louis the cauliflower plants were attacked by *Peronospora parasitica* in an epidemic form. In order to protect the plants various fungicides were sprayed upon them and as a result the lower sides of the leaves became covered with large wart-like growths. These were formed by the elongation of the cells of the palisade parenchyma. This peculiar condition is supposed to have been caused by the stimulating action of the copper salts in the fungicides.

The same speaker discussed the cause of "blue timber." This is said to be a serious affection of various timbers, especially of pine, hemlock, and spruce, and is quite different from the green color sometimes noted in hard woods. There appears to be no deposition of crystals of coloring matter in this disease, and the color is attributed to the massing of the hyphæ of a fungus which is always present in the medullary rays of the blue wood. The fungus is said to fructify on wood cut from the tree, but not on the living tree.

A report was made before the section of botany by D. T. MacDougal on The Desert Laboratory of the Carnegie Institution. The board of trustees of the Carnegie Institution has granted \$8,000 for the establishment and maintenance during 1902-3 of a desert botanical laboratory. F. V. Coville and D. T. MacDougal have been appointed by the board an advisory committee to have charge of the location and management of the laboratory. The proposed laboratory is designed for the thorough study of the physiological and morphological features of plants occurring in desert conditions, with particular reference to the relation of water, light, temperature, and other special factors to their development. In the discussion which followed the announcement of this grant a number of desirable localities were suggested as possible sites for the laboratory, the consensus of opinion favoring Tucson, Ariz., or that vicinity.

BACTERIOLOGY.

The Society of American Bacteriologists held three very full sessions, December 30 and 31, which were presided over by H. W. Conn. Nearly half the papers bore on agricultural bacteriology, and these included some of the most important read at the meeting.

In a paper on Oligonitrophilic Bacteria of the Soils, F. D. Chester explained that the oligonitrophilic bacteria are those which grow in nitrogen-free or nitrogen-poor media, and which possess the power of

utilizing the free nitrogen of the air. Nitrogen assimilation in the soil is not the result of the activities of a single organism, but of symbiosis of microaerophiles (*Clostridium pasteurianum*, several species of *Granulobacter* of Beijerinck, and *Radiobacter* of Beijerinck) with macroaerophiles (*Azotobacter* of Beijerinck). Either of these forms alone is unable to assimilate nitrogen, but mixed cultures of *Azotobacter* with the other forms showed gain of nitrogen of 4 to 7 mg. per gram of assimilated sugar in the medium. A form of *Azotobacter* isolated from Delaware soil was without the power of assimilating atmospheric nitrogen.

W. M. Esten exhibited an electric thermo-regulator, previously described by H. E. Ward, for regulating the temperature in incubators heated by electric lamps within the oven. Two pieces of this apparatus have been made, which have proved very satisfactory and efficient in maintaining the incubators at a constant temperature when they were being run at a higher temperature than the surrounding air. The apparatus was highly commended on account of its simplicity, reliability, and safety from fire.

The same author described the preparation of a number of culture media for determining the kind of bacteria in milk on the plate culture. A gelatin containing milk from which the casein has been removed, designated the custard-whey gelatin, was said to bring out the differences more prominently than a peptone-litmus gelatin, and to inhibit the growth of liquefying bacteria. By means of this custard-whey gelatin it is quite possible to tell the age of the milk by the appearance of the growth in the plate culture.

A paper entitled Milk Agar as a Medium for Demonstration of Proteolytic Enzymes, by E. G. Hastings, was presented by H. L. Russell. The culture medium was prepared by the addition of 10 to 12 per cent of skim milk to agar, and was found very satisfactory for showing the presence of digesting bacteria in dairy products. The medium was readily cleared up by the growth of such bacteria.

W. A. Stocking, jr., presented a paper on The Germicidal Action of Milk, in which he reviewed the claims that milk soon after it is drawn has a temporary inhibiting action on bacteria, as judged from the number of bacteria in the milk, and presented data in opposition to this belief which tended to show that no true germicidal action exists. It was found that in nearly all experiments the total number of bacteria during the first few hours decreased, but a study of the different forms present showed that while the non-acid species decreased the acid species increased regularly from the first. One case was mentioned in which alkaline species were present and inhibited or retarded the growth of the lactic organisms. The acid species were mostly the true lactic acid organisms. There seem to be only two or three types of acid organisms which persist, 99 per cent in

most cases being lactic acid organisms, the liquefiers and alkaline and other species, and most of the acid species not lactic, being crowded out.

Further Evidence of the Apparent Identity of *Bacillus coli* and Certain Lactic Acid Bacilli was presented by S. C. Prescott. The author prepared a series of cultures of bacteria corresponding to lactic acid bacteria isolated from grains and dairy products, and another series of cultures of bacteria corresponding to the coli bacillus isolated from fecal matter and from sewage polluted water. The two series were compared as regards cultural reactions, morphological characters, fermentative power, and pathogenic properties, and were found to be practically identical in these respects. The bacteria from both sources were shown to be somewhat pathogenic to guinea pigs. The general conclusion was drawn that the two classes of bacteria studied were actually identical. Bacteria corresponding to *Bacillus coli* are not confined to the intestinal tract. The mere presence of such bacteria in water does not, therefore, necessarily prove sewage pollution. Their presence in large quantities would be more indicative of such condition.

L. A. Rogers reported the isolation of a fat-splitting torula yeast from several samples of canned butter. The cells are elliptical, about $3.5\ \mu$ long and show little tendency to form chains or bunches. The torula shows a much weaker action than that of fat-splitting molds. The acid number of a pure butter fat inoculated with a milk culture of the torula increased in 2 weeks from 0.579 to 3.474. It ferments maltose slowly at 37°C ., but does not ferment lactose, galactose, levulose, mannose, or sucrose.

A Preliminary Chemical Study of Various Tubercle Bacilli was reported by E. A. de Schweinitz. Analyses of tubercle bacilli, mentioned elsewhere, were reported, and the relation of human and bovine tuberculosis was discussed. Investigations were reported which led the speaker to the opinion that the two diseases are due to the same organism. Tuberculosis was produced experimentally in a calf by inoculation with a culture of the tubercle bacilli from the organs of a child which died of the disease, and the bacillus isolated from the organs of the calf resembled the bovine more than the human form. Experiments with monkeys showed them to be very susceptible to the bovine tubercle bacillus.

A paper by M. Dorset on Egg Medium for the Cultivation of Tubercle Bacilli was presented in substance by E. A. de Schweinitz. This medium is easily prepared from fresh eggs. The tubercle bacillus grows very readily upon it, colonies appearing in 6 to 7 days after inoculation. (See p. 611.)

Other papers of rather less interest in this connection were: Contribution to the Study of Agglutinins, by W. W. Ford; The Reaction of

Certain Water Bacteria with Dysentery Immune Serum, by D. H. Bergey; Germicidal Properties of Glycerin in Relation to Vaccine Virus, by M. J. Rosenau; and The Bacterial Flora of the Oyster's Intestine, by C. A. Fuller, which showed a flora characteristic for the oyster.

ECONOMIC ENTOMOLOGY.

The papers on economic entomology were all presented before the Association of Economic Entomologists, which met December 26 and 27, or the Society for the Promotion of Agricultural Science. Several of these papers were also read at the zoological meetings.

Before the Association of Economic Entomologists the address of the retiring president, E. P. Felt, was on the subject of The Literature of American Economic Entomology. Notes were given on the extent and value of the various kinds of entomological publications, including bulletins, reports, journals, books, indexes, and more pretentious forms of literature, as well as newspaper articles. The greatest amount of literature has been written on the subject of the Rocky Mountain locust, followed by the San José scale, gypsy moth, chinch bug, cotton worm and bollworm, codling moth, Hessian fly, and periodical cicada, in the order named.

C. L. Marlatt gave an illustrated talk on the economic entomology of Japan. This included an account of the author's itinerary in his recent studies in Japan, with notes on the entomological work and literature in Japan, the institutions and laboratories for studying entomology in that country, and special notes on their work on the insects of rice, deciduous fruits, citrus fruits, tea, lotus, bamboo, etc., and on the silk industry.

E. P. Felt reported observations on the Grapevine Root Worm, an extensive outbreak of which occurred in Chautauqua County during the past season. Oviposition occurred about 7 days after the appearance of the adult beetles. The eggs were deposited from July 3 to August 19. The period of oviposition was about 3 days and the eggs were laid in clusters of 5 to 75. Each female laid about 100 eggs. The larvæ were found to travel 2 or more yards per hour and were able to make their way through 12 in. of soil in a comparatively short time. Cultivation of the soil was apparently effective against the pupæ. A modified curculio catcher was used with good results in catching the beetles. The insects were also destroyed by spraying with arsenate of lead in the laboratory, but in the field this insecticide gave negative results.

Dr. Felt also reported upon Results Obtained with Certain Insecticides. It was found that a 20 per cent mechanical mixture of crude petroleum applied April 7, when followed by an excessively rainy period, destroyed nearly all the scales without injuring the trees. Pear

and peach trees were sprayed with crude oil in various forms without injury except when it was undiluted, and good results were also obtained on plums. No injury was produced from a 20 per cent mixture applied in July. Whale-oil soap also gave good results in destroying the San José scale when applied at the rate of $1\frac{1}{4}$ lbs. per gallon of water. Lime, sulphur, and salt was applied April 7 to about 60 trees, but the period following was very rainy and it appeared to have but little value. Orchardists in the same neighborhood, however, had excellent results from this insecticide.

A. L. Quaintance gave Further Notes on the Lime, Sulphur, and Salt Wash in Maryland. The author's previous report that this treatment was ineffective was reversed by later observations. The effectiveness of the insecticide persisted for several months.

The lime-sulphur-salt mixture was also discussed by W. E. Britton. Pear, peach, quince, and plum trees in Connecticut were sprayed with this mixture in April. In June the percentage of living scales varied from zero to 7 per cent. The mixture was as effective as any other insecticide, and was used by orchardists on large orchards with good results. During a prolonged discussion of this subject, participated in by various members, C. L. Marlatt stated his belief that at present the best remedies for San José scale are the lime-sulphur-salt mixture, pure kerosene, and kerosene emulsion.

C. B. Simpson reported Observations on the Life History of the Codling Moth, illustrated by lantern slides. In the author's experiments it was found that $\frac{1}{8}$ to $\frac{1}{4}$ of the eggs were laid on the fruit, while most of the eggs were laid on the leaf; the larvæ may come to maturity in the leaves without the presence of apples. About 80 per cent of the first generation of larvæ were found to enter at the calyx, and 28 per cent of the second generation. The average length of life of the moth was found to be 4 days. It is believed that there are 2 generations per year. A period of 50 days was noted between the maximum appearances of larvæ. With regard to the broods of this moth, it is stated that there are probably 1 in Canada, New Jersey, and parts of Idaho, 2 in Oregon and the Upper Austral Zone in general, and 3 in the Lower Austral Zone.

In a note on A Criticism upon Certain Codling Moth Investigations, F. L. Washburn gave special attention to a criticism by Cordley and Gillette of his work in Oregon. The author believes that the number of broods of the codling moth in western Oregon is still in doubt. The same author read a paper on the Distribution of the Chinch Bug in Minnesota, showing that during the past season it was confined to the southern parts of the State. This limited distribution it is believed is determined partly by the methods of farming employed in different parts of the State.

J. Fletcher discussed the question Can the Pea Weevil be Exterminated? It was argued that, since the pea weevil has no other food plant

than the common pea, it could probably be exterminated by interrupting the cultivation of the peas for 1 or 2 years, or by thoroughly fumigating the seed peas. The great practical difficulties with either one of these plans were carefully discussed. The author recommends harvesting the peas a little earlier in the fall, and immediately thrashing and sacking the peas so as to prevent the escape of the beetles in the fall, and the treatment of all seed peas with bisulphid of carbon.

W. B. Alwood presented notes on Plants Injured by 17-year Locusts. It was stated that the locust did not deposit eggs in an orchard which was previously sprayed with Bordeaux mixture. The eggs were deposited in a considerable variety of plants, including 14 families, 30 genera, and 33 species.

V. L. Kellogg gave brief notes on observations made on Aleurodidae and Coccidae. A number of new species and new host plants were discovered for these insects, and investigations were made extending throughout the Sierra Nevada Mountains. The Monterey pine on the grounds of Stanford University were badly attacked by the bark beetles, and a tar-canvass jacket was adjusted to the trees for the purpose of conducting some fumigation experiments. It was found that hydrocyanic-acid gas destroyed the insects in all stages, while carbon bisulphid was of little value in this respect.

A. F. Burgess read a paper on Economic Notes on Coccinellidae. Statistical data were presented, including the number of eggs laid by various species of ladybirds, the period occupied by the different stages of development, and the number of plant lice eaten by the ladybirds during their various stages.

In a paper on *Melanoplus femoratus*, J. L. Phillips stated that this insect caused serious damage in Virginia to pasture and meadow grasses, wheat, and the foliage of apple trees.

The position of the setae of San José scale in the tissues of imported plants was discussed by G. B. Symonds. It was found that the beak of the San José scale is inserted in a straight line in fruits, through the cell bodies and not between the cells in the cell membranes. In wood, the beak is bent at a right angle just beneath the surface of the bark.

H. Osborn discussed a method for mounting dried Coccidae for permanent preservation. Specimens were mounted between strips of mica of the size of microscopic slides. They were thus protected against breaking, moisture, and museum pests.

Papers on the insects of the year and minor entomological notes were presented by E. P. Felt, of New York; J. Fletcher, of Canada; H. Osborn, of Ohio; A. L. Quaintance, of Maryland, and C. M. Weed, of New Hampshire, some of which brought out discussions in regard to particular insects. J. Fletcher stated that in Manitoba hopper-doers were largely abandoned in the fight against grasshoppers, for more effective poisoned baits, which consist of a mixture of bran or

horse manure and Paris green. In the experiments reported by the author horse manure was found to be the more effective. The bait was prepared so as to contain 1 lb. of Paris green and 1 lb. of salt to 50 lbs. of horse manure.

In a paper on Plant Environment and Insect Depredations, F. W. Rane called attention to the value of proper cultural methods, which may be so practiced as to reduce insect ravages to a minimum. The necessity of devising practical remedies available to ordinary farmers and fruit growers was emphasized.

The three following papers were presented before the Society for the Promotion of Agricultural Science. The Importance of Injurious Insects Introduced from Abroad, by E. P. Felt, discussed the introduction and distribution of the more important insects, gave estimates of the extent of the damage done by a number of them, and presented a classified list of the important species. Notes were also given on a number of beneficial species which have been introduced.

H. Osborn discussed insect problems in Ohio, giving notes on a number of injurious insects and estimates of the damage done by them. The total loss of farm and vegetable crops due to insects was placed at 10 per cent. Some of the insects receiving especial attention were the Hessian fly, San José scale, cankerworm, and the codling moth. In the discussion of this paper it was stated that some varieties of wheat were found more resistant to the Hessian fly than others, but that it was not always practical to grow the more resistant varieties. Decoy crops were also mentioned as successful when properly attended to. The use of lime-sulphur-and-salt wash against the San José scale in New York was reported by W. H. Jordan as very successful in experiments conducted during one season.

A paper by F. M. Webster, entitled The Use of Arsenate of Lead Against the Codling Moth, was read by title. Experiments on the use of arsenate of lead were conducted by the author in 1901, with results which were considered encouraging. In 1902 practical tests were made by a number of fruit growers in Ohio and Indiana, the results on the whole being considered favorable to the use of this insecticide. In one instance the percentage of wormy apples from sprayed trees was 3.6 and from unsprayed 79.5; in another instance 1.4 and 54, respectively; and in a third experiment 6.9 and 69, respectively.

Before another body L. O. Howard spoke briefly regarding efforts of the Division of Entomology to lessen the damage that insects are doing to agricultural interests, which is estimated at \$300,000,000 per annum, and for the control of which the Government spends only \$150,000 per annum. For the purpose of classifying the work insects are divided into groups, e. g., those affecting field crops, orchard fruits, truck crops, sugar beets, etc.; those concerned in silk produc-

tion, and those injurious to mankind by carrying diseases. A study of the life history of these insects is made for the purpose of revealing their most vulnerable points, and then attacks upon them are made at those points. This method has enabled the Division of Entomology among other things, to check the ravages of the cotton-boll weevil by cultural methods, and to point out ways of lessening the ravages of the codling moth in the Northwest. The Division has also introduced into this country a number of beneficial insects, such as the ladybird beetle from Australia, which has saved the orange crop of California, and the insect from Algeria which fertilizes the Smyrna fig and makes it possible to successfully grow this fruit in California.

PHYSIOLOGY.

A number of papers of especial interest to students of nutrition were presented at the meetings of the American Physiological Society. Among these the following may be mentioned: New Experiments on the Physiological Action of the Proteoses, by L. B. Mendel and F. B. Underhill; Further Observations of the Movements of the Stomach and Intestines (with demonstration), by W. B. Cannon; Salivary Digestion in the Stomach, by W. B. Cannon and H. F. Day; Biological Relationship of Proteids and Proteid Assimilation, by P. A. Levene and L. B. Stookey; On Digestion of Gelatin, by P. A. Levene and L. B. Stookey; On the Nucleoproteids of the Pancreas and Thymus, with Special Reference to their Optical Properties, by A. Gamgee and W. Jones. Professor W. O. Atwater read a paper on the Sources of Muscular Energy, in which the results of his experiments with the respiration calorimeter were quoted with especial reference to the value of different materials as sources of energy in the animal body.

ENGINEERING.

A paper on Agricultural Engineering, by Elwood Mead, noted the revolution in the conditions of farm life and farm labor in the last fifty years. These have necessitated greater attention on the part of the farmer to problems in agricultural engineering, the substitution of power for hand labor, and the use of more effective implements and machines. A number of the agricultural colleges of this country have turned their attention to this matter, incorporating in their courses of instruction a study of the principles on which efficient machines rest; and in European countries institutions have been established for the study and improvement of farm machinery, which are supported by the State. The lack of classified and verified information was mentioned; and the desirability of efforts in this direction by the National Department of Agriculture was pointed out.

C. G. Elliott described *The Drainage Problems of Irrigation*, a new series of problems which confront the owners of irrigated lands. The

leakage from canals and overirrigation have destroyed the productive-ness of land by producing saturation of soils in certain localities and resulting alkali conditions. Well-directed drainage operations, it was believed, will reclaim such lands and protect those which are threatened with the evil.

The Hydrographic Work of the U. S. Geological Survey was described by H. H. Presley, who reviewed the work on the measurement of streams and the relation of this to problems in irrigation.

The Road Material Laboratory of the Bureau of Chemistry of this Department was the subject of a paper by L. W. Page. He mentioned the different road-making materials and pointed out the wisdom of having them tested by laboratory methods before they are used in construction. Differences in the amount and character of traffic may determine the kind of material that is required. The binding materials present with crushed rocks of various kinds were said to have much to do with the value of these materials for surfacing roads.

The Cementing Power of Road Materials was presented by A. S. Cushman. The cementing value is a phenomenon of the same nature as the plasticity of clays, and results in the road-material laboratory of this Department seem to point to the fact that plasticity is dependent on a colloidal condition of the particles. Surfaces of roads are continually being powdered by the effect of traffic wear and weathering, and the particles are continually being cemented and recemented. If the material of the road lacks plasticity the particles blow and wash away too readily. The binding quality of such rocks as limestones and dolomites is a function of the hydrogel impurities, present usually either in the form of silicic acid or hydrated oxid of iron.

In a paper on The Metric System, J. Burkitt Webb opposed the introduction of this system from the standpoint of engineering. Standards of length lie at the foundation of all our important and accurate manufacturing and engineering work, and an examination of the necessities of this work, in both its theoretical and practical parts, was stated to show that a change to the metrical system would be not only very expensive but detrimental. He argued that 16 (the subdivisions of the inch) is in many ways a better number than 10 as the basis of a system; and he attempted to point out some of the peculiar collateral advantages of 16.

AGRICULTURE AND ECONOMIC SCIENCE.

Most of the papers presented at the meetings of the Society for the Promotion of Agricultural Science have been noted elsewhere under appropriate headings. The presidential address, delivered by W. H. Jordan, on Values in Science, will appear in the next issue of this journal.

A report was received from the committee acting in cooperation with a committee of the Association of American Agricultural Colleges and Experiment Stations, for the purpose of requesting the board of trustees of the Carnegie Institution to apply some portion of the Carnegie gift to the promotion of scientific research in its relation to agriculture. In the memorial presented to the board of trustees certain general lines were suggested as suitable for research work. The communication was considered at a meeting of the board of trustees and returned to the committee with a request for concrete suggestions rather than generalizations. The committee was continued with a view to making such suggestions.

W. J. Beal discussed briefly courses of study in agricultural colleges, mentioning some of the features of instruction in agriculture in early years, and expressing the opinion that allied groups of subjects should be elective by students soon after entering college. This brought out a spirited discussion upon entrance requirements and agricultural education in general.

The same speaker presented some biographical notes on the late Robert C. Kedzie, who was a member of the society.

A paper on The Diameter of Wool Fibers from Different Breeds of Sheep of the United States and Canada, by T. F. Hunt, was read by title. Measurements of the wool from 1 to 5 sheep of 13 breeds were made by Lamotte Ruhlen, and showed a range in the diameter of the fibers from 4.28 to 1.8 centimillimeters, the extremes being represented by the Leicester and the American Merino breeds.

B. E. Fernow presented a paper on The Farmers' Wood Lot, in which the importance of looking after the wood supply more carefully was emphasized. Estimates were given of the increased consumption of wood products in the United States and foreign countries. The export trade of the United States was stated as having doubled during the last 10 years. At the present rate of consumption the timber supply of the United States in view will, according to the author, be exhausted within 30 years. As 60 to 100 years are required for the production of millable timber, and for other reasons, it was shown that few farmers can engage in this business. For the production of wood for fuel purposes, however, the time required is only 20 to 30 years, and waste lands may be utilized for this purpose.

Before the section of Social and Economic Science a paper on Requisites in Crop Reporting was read by H. Parker Willis, which dwelt at some length on the purpose and importance of crop reports, and the reasons for lack of confidence in such reports as now prepared. The requisites pointed out were in brief (1) perfect confidence in the man in charge of the reports, his office force, and his correspondents; (2) publicity as to methods of operating; (3) dealing with facts rather

than estimates, and (4) the uniting of all Government statistical agencies under one management.

The Sources and Margin of Error in Census Work was the subject of a paper by Le Grand Powers, Chief Statistician for Agriculture, U. S. Census. This dealt mostly with errors in the census of agriculture, the principal sources of which were said to be omissions and duplications on the part of census enumerators. In most branches of census work omissions and duplications nearly balance, but in the census of agriculture, comparisons with the records of assessed land show that the omissions exceed the duplications, the excess amounting in farm areas to 40,000,000 acres, or 5 per cent. The omissions are most numerous in sparsely settled regions where there is much irregular land surface; the duplications, in thickly settled communities, especially where tenant farming prevails and both tenant and proprietor report on the same items.

Discussing the Economic Value of the Remaining Public Lands, J. D. Whelpley pointed out the extent and conditions of these lands and offered some suggestions regarding their management, the most important of which was that speculation in them should be stopped by limiting their disposition to those only who intend to build homes on them.

The Social Aspects of the Irrigation Problem were presented in a paper by Guy E. Mitchell.

Miss Louise Klein Miller, Director of the Lowthorpe School of Horticulture and Landscape Gardening for Women, discussed School Gardens, pointing out the function of the school garden as an agency for promoting logical instruction in nature study and elementary agriculture. A brief account was given of the school garden movement in Europe and America, followed by a more detailed account of Miss Miller's own work at Groton, Mass.

NATIONAL DEPARTMENT OF AGRICULTURE.

The organization and the scientific and economic work of this Department were presented by a number of the chiefs of bureaus at various meetings of the association during the week.

The work of the Weather Bureau, as described by Willis L. Moore, is the broadest survey of the kind ever made, with an extent north and south of 3,000 miles and east and west an equal distance. The practical workings of the Bureau were mentioned, and some striking evidences of the value of its predictions on land and sea were cited.

The economic work of the Bureau of Soils was outlined by Milton Whitney. Maps were exhibited to illustrate the location and extent of the soil surveys made by the Bureau during the past four years, and brief reference was made to some of the results of economic importance. Special mention was made of the Sumatra tobacco industry

in the Connecticut Valley, and the recent discovery of a soil in Texas said to produce tobacco with the peculiar aroma of the Cuban product. In the Yazoo Valley of Mississippi a way has been pointed out whereby thousands of acres of flooded bottom land can be reclaimed for cotton growing. In the West the officers of the Bureau have satisfied themselves that much of the 6,000,000 acres of alkali soil can be made productive by proper methods of drainage, and they are attempting to demonstrate their theory to the people in the alkali regions.

A. C. True, speaking of the Office of Experiment Stations, considered it first, in relation to the agricultural colleges and experiment stations, as a general agency for the promotion of agricultural education and research. On the economic side these institutions are doing much to increase the amount of production and to raise its quality through the application of science to agriculture. On the social or educational side they not only provide much material for effective courses of study in the theory and art of agriculture, but also furnish the motive for definite technical education in agriculture; and this is changing the intellectual attitude of the farmer from conservatism to progressiveness, broadening and deepening his intellectual life—a service as important, to say the least, as improving his material condition. Some of the leading lines of work of the Office were mentioned, such as the publication of this journal and numerous technical and popular bulletins, the formulation of the principles on which institutions for agricultural research should be organized and managed, the promotion of technical education for the farmer, by encouraging the formulation of a distinct science of agriculture and its reduction to “pedagogic form” to meet the requirements of different grades of students, the organization and management of agricultural experiment stations in Alaska, Hawaii, and Porto Rico, and the investigation of problems in the nutrition of man and in irrigation, in cooperation with other scientific organizations.

Descriptions of the work in several other bureaus and divisions have been noted elsewhere.

The meetings afforded opportunity for the visitors to inspect the laboratories of the Department, which was embraced by many. This, with the discussions of the work of the various branches in general and of special lines of work in the different section meetings, conveyed to many a much clearer idea of the objects, scope, equipment, and workings of the Department in various lines.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

Proceedings of the seventeenth convention of the Association of Agricultural Experiment Stations in the German Empire (*Landw. Vers. Stat.*, 57 (1902), No. 1-2, pp. 1-101).—The seventeenth meeting of this association was held at Hamburg September 21 and 22, 1901, and was presided over by the president, F. Nobbe.

Among the subjects under consideration were the determination of citrate-soluble phosphoric acid in Thomas slag, the Neubauer method of potash determination, the Gunning modification of the Kjeldahl method of nitrogen determination, the allowable water content of molasses feeds, and their analysis, the determination of potash salts in mixed potash fertilizers, fundamental principles in the examination of bran, the relation of the agricultural experiment stations to the work of the association, the preparation of feeding stuffs for analysis, with directions for sampling, the changes produced by micro-organisms in foods and feeding stuffs during storage (*E. S. R.*, 13, p. 581), the microscopical examination of rape-seed cake, the money value of feeding stuffs, and the present status of the movement for the introduction of uniform atomic weights.

An unfavorable report upon the accuracy of the Neubauer method was made by Soxhlet and no action was taken by the association. Comparative tests of the Gunning modification of the Kjeldahl method (*E. S. R.*, 14, p. 118) and the method of the association on different feeding stuffs were reported by Kellner. Further testing of the Gunning modification was recommended. A water content of 20 per cent in molasses feed and 25 per cent in peat molasses was adopted as allowable. The determination of molasses in molasses feeds was assigned for further study. The recommendation was adopted that potash in fertilizers be reported only as K_2O . Wittmack discussed the purity of bran and its determination, and reported several feeding experiments with different animals. It was recommended that all feeding stuffs for analysis should be prepared fine enough to pass through a 1-mm. sieve. Emmerling discussed the microscopical examination of rape-seed cake. A committee of three was appointed to determine the relative value of nutrients—protein, fat, and carbohydrates—in feeding stuffs and report annually to the association.

The action of distilled water upon lead, F. CLOWES (*Chem. News*, 86 (1902), No. 2236, p. 168).—The author found that when lead was placed in contact with ordinary distilled water a white deposit was formed which contained lead and a certain amount of lead went into solution in the water. The lead in solution appeared to be in the form of hydroxid. That in the white deposit was found to be a hydroxycarbonate containing three molecules of carbonate to one of hydroxid. Investigations in which bright sheet lead of great purity was exposed to the action of boiled distilled water *in vacuo* or in different gases showed "that dissolved oxygen is the cause of the action of distilled water upon lead, the subsequent action of carbonic acid leading to the production of hydroxycarbonate."

The determination of iron in natural waters, L. W. WINKLER (*Ztschr. Analyt. Chem.*, 41 (1902), No. 9, pp. 550-552).—In the colorimetric method described ammonium sulphid is used instead of the potassium ferrocyanid commonly employed.

The determination of nitric acid in water by Noll's method, W. P. KASCHKADAMOV (*Jour. Ochrani. Narod. Sdrav.*, 12 (1902), p. 491; *abs. in Chem. Ztg.*, 26 (1902), No. 34, *Repert.*, p. 309).—The method is recommended.

The volumetric determination of nitric acid in drinking waters, O. SCHMATOLLA (*Apoth. Ztg.*, 17 (1902), pp. 697, 698; *abs. in Chem. Centbl.*, 1902, II, No. 18, p. 1152).—A modification of the Marx method is recommended.

The litmus-paper test for milk, H. D. RICHMOND (*Chem. News*, 86 (1902), No. 2238, pp. 192, 193).—The use of litmus paper for testing the acidity of milk is considered very unsatisfactory.

Methods for the estimation of the proteolytic compounds contained in cheese and milk, L. L. VAN SLYKE and E. B. HART (*New York State Sta. Bul.* 215, pp. 81-102).—This gives in detail the methods outlined in Bulletin 203 of the station (E. S. R., 13, p. 1087) and presented in full before the Association of Official Agricultural Chemists (E. S. R., 14, p. 108).

Concerning the coagulable material in egg white, L. LANGSTEIN (*Beitr. Chem. Physiol. u. Pathol. Ztschr. Biochem.*, 1 (1901), pp. 83-104; *abs. in Ztschr. Untersuch. Nahr. u. Genussmittel*, 5 (1902), No. 14, p. 663).—Analytical data are reported and discussed.

Concerning the character of free fatty acids, E. A. LÖSCH (*Inaug. Diss.*, St. Petersburg, 1902; *rev. in Chem. Ztg.*, 26 (1902), No. 30, *Repert.*, p. 108).—Under similar conditions butter and lard become more rancid, that is, form free fatty acids more energetically, than sunflower seed and almond oil. When butter becomes rancid, strong-smelling products are produced. On the other hand, when the liquid fatty oils become rancid such products are much less abundant, but bodies having a sharp and burning taste are produced. The increase in weight when fats become rancid is very slight, being greatest in the experiments reported with sunflower-seed oil. Generally speaking, the amount of volatile fatty acids is not large, while the amount of free nonvolatile fatty acids is much increased.

The estimation of starch in cereal grains, L. LINDET (*Jour. Pharm. et Chim.*, 6. ser., 14 (1901), pp. 397-400; *Ann. Chim. Analyt.*, 7 (1902), pp. 41-43; *abs. in Ztschr. Untersuch. Nahr. u. Genussmittel*, 5 (1902), No. 14, p. 665).—In this method of estimating starch in cereals the proteid material is removed by digestion with pepsin and hydrochloric acid and the starch which remains behind is treated with sulphuric acid and soda and then measured by determining the glucose and dextrin in an aliquot portion.

Filtration in determination of crude fiber, R. W. THATCHER (*Jour. Amer. Chem. Soc.*, 24 (1902), No. 12, pp. 1210, 1211).—The author modifies the official method by filtering through asbestos wool placed in a large funnel on a platinum cone. The residue is washed into a platinum dish, the water evaporated, and the determination completed as usual. This procedure is especially adapted to the glycerol-sulphuric acid mixture used in the König method for fiber.

The analysis of vanilla extract, A. L. WINTON and M. SILVERMAN (*Jour. Amer. Chem. Soc.*, 24 (1902), No. 11, pp. 1128-1135).—The authors give a modification of the Hess and Prescott method for the determination of vanillin and coumarin (E. S. R., 13, p. 420), which is designed to shorten the process without diminishing the accuracy of the method. The modification consists in the use of a larger quantity of 2 per cent ammonia and weighing the vanillin and coumarin immediately after evaporation of the ether solutions. Analyses are also given of a number of genuine and artificial vanilla extracts.

Uniform methods for the examination and valuation of foods, condiments, and commercial products in the German Empire (*Vereinbarungen zur einheit-*

lichen Untersuchung und Beurtheilung von Nahrungs- und Genussmitteln sowie Gebrauchsgegenständen für das Deutsche Reich. Berlin: J. Springer, pt. 1, 1897, pp. XIII + 109; pt. 2, 1897, pp. XII + 184; pt. 3, 1903, pp. X + 184).—This work contains the methods for the examination of foods, condiments, and commercial products decided upon by a commission of food chemists appointed at the request of the Imperial Board of Health. A valuable point to be noted in connection with the work is the very full bibliography which accompanies each of the principal sections.

The chemistry of india rubber, C. O. WEBER (*London: Charles Griffin & Co., Ltd.; Philadelphia: J. B. Lippincott Co., 1903, pp. XI + 314, pls. 5, figs. 16*).

Analysis of resins, balsams, and gum resins, K. DIETERICH, transl. by C. SALTER (*London: Scott, Greenwood & Co., 1901, pp. XIV + 340*).

Physical and chemical methods for the quantitative determination of organic compounds, W. VAUBEL (*Die physikalischen und chemischen Methoden der quantitativen Bestimmung organischer Verbindungen.* Berlin: Julius Springer, 1902, vol. 1, pp. XIV + 593, figs. 74; vol. 2, pp. XI + 530, figs. 21).—Volume 1 deals with physical methods and volume 2 with chemical methods.

BOTANY.

The influence of varying amounts of carbon dioxide on photosynthesis, H. T. BROWN and F. ESCOMBE (*Proc. Roy. Soc. [London], 70 (1902), No. 464, pp. 397-413, pls. 6; abs. in Bot. Centbl., 90 (1902), No. 11, pp. 293, 294*).—A series of plants was experimented with to test the effect of varying amounts of carbon dioxide in the air on the photosynthetic processes of the leaves and on the growth of the plants. In one series leaves which were in some instances still attached to the plant were inclosed in air-tight cases through which air was passed, and the carbon dioxide content determined both before and after its passage over the leaf. In these experiments it was found that by increasing the carbon dioxide in the air an increase was noted in the photosynthetic power of the leaf in nearly the same proportion. In all cases where the illumination of the leaf was good, the photosynthesis was somewhat in excess of what might be expected from the increased amount of carbon dioxide. This was attributed to the fact that in the experiment the air which contained the greater amount of the gas also carried more moisture than ordinary air.

Experiments were conducted in a similar manner in which the illumination was insufficient and similar results obtained. Seedling plants were experimented with by inclosing them in vessels and subjecting them to varying amounts of carbon dioxide, the experiments indicating that the plants were not stimulated to increased growth by increasing the amount of carbon dioxide. On the other hand, there appeared to be a slight diminution in the increase of dry matter and a less development of leaf area. There were also certain morphological differences which are noted elsewhere (see below).

Similar experiments were conducted in a small greenhouse and carried on approximately from 1 to 2 months. The effect of an increased amount of carbon dioxide became most apparent within a week or 10 days of the beginning of the experiment. A marked difference was noted in the habit and general appearance of the plants owing to a stimulation of axial growth accompanied by a more or less pronounced shortening and thickening of the internodes. As it appeared evident that the increased photosynthesis did not contribute to the increase of dry matter of the plant, it is concluded that the transformation, translocation, and metabolism of the leaf reserves could not keep pace with the increased tendency to produce an extra amount of plastic material from the atmosphere. Without exception all the plants experimented with seemed to be best adapted to the atmosphere containing the ordinary proportion of carbon dioxide. The response which they made to slight increases

in this amount appears unfavorable to the growth and reproduction of the plants, and it is believed that the comparatively sudden increase of the carbon dioxide in the air to an extent of 2 or 3 times the present amount would result in the speedy destruction of nearly all our plants.

The influence of an excess of carbon dioxide in the air on the form and internal structure of plants, J. B. FARMER and S. E. CHANDLER (*Proc. Roy. Soc. [London]*, 70 (1902), No. 464, pp. 413-423, figs. 5; *abs. in Bot. Centbl.*, 90 (1902), No. 11, pp. 296, 297).—The plants experimented upon as reported in the previous article were investigated by the authors to determine the relative dimensions of the internodes, the average relative area of the leaves, number of stomata per unit of leaf surface, anatomical differences in the stems and leaves, and the relative amount of starch and other cell contents in the two series.

The results are given in detail, from which it appears that an excess of carbon dioxide checks the growth of the internodes while prolonging the period of growth. The leaf area is more or less reduced by checking the growth of the leaves at an early stage. The absolute number of stomata per unit area of leaf surface is considerably increased, although the relative proportion of stomata to the number of epidermal cells remains practically constant. The anatomical structure of the leaf tissue is not materially altered. In the stem the xylem areas are less lignified, but the phloem shows no alteration. As a rule, there is a considerable increase of starch and a diminution of the amount of tannin and crystals of calcium oxalate. No alteration could be detected in the roots as a consequence of the increase in the carbon dioxide content of the air. These results are held to differ in a remarkable way from those obtained by Téodoresco (*E. S. R.*, 10, p. 610), but that author compared plants grown in an atmosphere containing carbon dioxide with those grown in an atmosphere which was almost deprived of this source of carbon.

Investigations in chlorophyll assimilation of leaves, E. GRIFFON (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 5, pp. 303-305).—Experiments are briefly reported on the effect of illuminating the different surfaces of the leaf on its chlorophyll assimilation. Leaves were placed in flattened tubes, so that the different surfaces could be subjected to direct and diffuse illumination, and the amount of gas given off determined. Differences were noted for the different surfaces of the leaf, and considerable inequality was observed, the differences seeming to be somewhat dependent upon the thickness of the leaf. In thick leaves, such as the cherry laurel, the proportion of assimilation of the upper and lower surface was as 100:48. In thin leaves, such as the maple, the proportion was 100:88, and in the case of leaves in which the mesophyll is more or less homogeneous, as in the case of the bamboos, the proportion was 100:92. In the case of leaves whose under surface is covered with hairs, as the linden, raspberry, and others, the difference was quite marked, and for such species as *Eleagnus*, in which the lower surface is covered with a dense covering of scales, the proportion fell to 100:36. The results seem to indicate that the palisade parenchyma of the leaves is adapted to the decomposition of carbon dioxide.

The influence of colored light on vegetation, G. T. GRIGNAN (*Rev. Hort. [Paris]*, 74 (1902), No. 16, pp. 388-390).—A review is given of the work of Zacharewicz, in which fruits were grown under colored screens, and of Flammarion's experiments with strawberries and other plants grown under the influence of different colored light.

The influence of different colored light upon plants, C. FLAMMARION (*Ann. Min. Agr. [France]*, 21 (1902), No. 2, pp. 395-397).—In continuation of the author's investigations on this subject (*E. S. R.*, 12, p. 909), experiments are reported in which *Gladioli* were grown under white, red, green, and blue lights. At the same time the bulbs of *Montbretia* were grown under similar conditions. The effect of the different illuminations is shown in tabular form, from which it appears that the plants are not similarly affected by the different kinds of light. Summarizing his work on

the effect of colored light upon plants, the author claims to have shown that red rays favor the development of most plants, and the exclusion of blue and green is also favorable to their best growth.

The influence of electricity upon plants, C. FLAMMARION (*Ann. Min. Agr. [France]*, 21 (1902), No. 2, pp. 400, 401).—A report is given of experiments in which beans were planted between copper and zinc plates buried in the ground and connected with a Leclanché cell. The author has experimented with this form of apparatus since 1894, and comparing the results finds considerable variation. The contradictory results are attributed to different conditions of the atmosphere, moisture, and temperature, all of which must be considered in similar experiments. In general, however, the electric current exercised a stimulating effect on the growth and production of the plants.

Certain relations of plant growth to ionization of the soil, A. B. PLOWMAN (*Amer. Jour. Sci.*, 4. ser., 14 (1902), No. 80, pp. 129-132).—A description is given of a series of experiments on the relation of plants to electricity, conducted at the Harvard Botanic Garden. Among the facts recorded the author states that seeds placed near the anode are always killed by currents amounting to 0.003 ampere or more if continued for 20 hours or longer, while seeds placed near the cathode have in most cases been but little affected and under some conditions stimulated by the currents. When the seeds were germinated in water the difference was most pronounced when a relatively heavy current was passed through the water for only a short time. In this case the seeds near the anode were killed while those near the cathode were apparently uninjured. These differences are attributed to the dissociation of the atoms by the electric current. When seeds are germinated in distilled water through which a weak current is forced, the oxygen ions are in excess in that part of the solution where the stimulation occurs, and the hydrogen ions are in excess where the plants are killed. The different effects are believed to be produced by the electrical charges of the ions rather than by any mere chemical activity of the atoms. When seeds are placed in solutions of various acids, bases, or salts of a degree of concentration far below the killing point, they will germinate as well as in ordinary distilled water, but when a current of electricity of sufficient strength to propel the ions is passed through the solution that part about the anode becomes destructive to plant life.

From these facts it is concluded that negative charges stimulate and positive charges paralyze the embryonic protoplasm of plants. In support of this theory it is shown that if a flower pot containing several lupines of about 4 weeks' growth is charged with positive electricity the plants cease to grow, gradually lose their turgidity, and finally die; while if the charge be negative these effects are not produced, but the plants are stimulated. When seedlings are grown in an aqueous culture medium through which a weak current of electricity is passed, the root tips turn toward the anode. Normally the plant body is electro-positive to the soil in which it grows. The positive charge of the plant attracts the negative ions of the soil to its roots, and any circumstance which would facilitate the electrical interchange would be expected to be beneficial to the plant, as the reverse conditions would be detrimental. These phenomena are dependent not only upon temperature, light, aeration, and moisture, but also upon the nature of the electric current used, degree of dissociation, physical state of the ions, etc.

Effect of the composition of soil on the minute structure of plants, H. B. DORNER (*Proc. Indiana Acad. Sci.* 1901, pp. 284-290, pls. 2).—The object of the experiment reported was to determine whether the variations in soil produce other than gross changes in plants. A number of well-known plants were grown in loam, clay, and sand under otherwise identical conditions. The change in soil was found to decrease the size of the plant, its leaf surface, length of petioles, diameter of the stem, length of internodes, masses of roots, and to cause variation in color, the decrease

being from the loam to the sand. In the histological characters there was found to be a decrease in the transpiring surface, the woody tissues of the root, the development of wood, and a few other characters in the same way as noted for the decrease in gross characters. In most cases the number of stomata was largest on the plants grown in the sand. In 5 cases out of 6 the thickest leaves were produced on the plants grown in the loam, and this increase was caused by a general increase in thickness of all the tissues in the leaf. In those plants bearing trichomes they were found least abundant on the plants grown in loam. In conclusion it is stated that the changes in gross structure were general for all the plants studied, while the changes in minute structure were more specific than general.

Influence of sulphocyanic acid on the growth of *Aspergillus niger*, A. FERNBACH (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 1, pp. 51, 52).—The author having observed the continued growth of *Aspergillus niger* in Raulin's liquid, in which ammonium sulphocyanate had been accidentally introduced, was led to investigate the subject further, and cultures were prepared containing known amounts of the chemical which were seeded with the spores of the mold. The tubes containing the cultures were subjected to the same conditions for a period of 6 days, when it was found that ammonium sulphocyanate had in no appreciable way checked the development of the mycelium. It was considered remarkable, however, that the fructification of the mold had been almost entirely checked by the addition of the sulphocyanate.

The presence of rennet in plants, M. JAVILLIER (*Bul. Soc. Chim. Paris*, 3. ser., 27 (1902), No. 15, pp. 818-822).—A brief review and bibliography is given of investigations which showed the presence of rennet or similar substances in the juice of a number of plants, and the experiments of the author with rye grass (*Lolium perenne*) are described. The author found in the juice extracted from this grass a substance which is capable of coagulating milk, and this power was shown in the different dilutions studied. When 50 drops of the expressed juice were added to 10 cc. of sterilized milk, the coagulation was effected in from 2 to 4 hours. Oxalate of potash was found to retard the coagulation while the salts of lime favored it. When the lime and magnesia salts were neutralized by sufficient potassium oxalate, no coagulation was produced. In addition to this plant, the author gives a list of 17 species representing a wide range of plant families in which he has detected the presence of rennet in either the leaves, stems, or seeds.

Seed selection in Belgium, E. LECLERCQ (*L'Ing. Agr. Gembloux*, 13 (1902), No. 2, pp. 75-81).—On account of the great improvement in live stock in Belgium, which has been brought about through various societies maintained for that purpose, an attempt has been made to establish societies for the improvement of varieties of seeds and plants. The effect of various factors upon plant improvement, such as selection, heredity, atavism, etc., is described, and statements are given regarding the methods which are proposed to be followed by cooperative societies in seed and plant improvement.

ZOOLOGY.

Birds of a Maryland farm. A local study of economic ornithology, S. D. JENN (*U. S. Dept. Agr., Division of Biological Survey Bul.* 17, pp. 116, pls. 17, figs. 41).—This bulletin contains an account of observations made on a farm at Marshall Hall, Md., during frequent visits from 1895 to 1902. The purpose of these observations was to determine the economic relations of all the birds found under certain definite local conditions. The birds found on the farm are classified into several groups according to their feeding habits. Meadow larks, grasshopper sparrows, quails, mourning doves, crows, blackbirds, and certain other species fed chiefly in open fields. Field sparrows, chipping sparrows, song sparrows and other native sparrows, as well as English

sparrows, prefer to feed under cover of bushes or herbaceous plants. The other birds observed on the farm are of less limited distribution, and include kingbird, oriole, cedar bird, catbird, hawks, owls, turkey buzzards, kingfishers, etc. A collection was made of insects, seeds, and plants on the farm in order to determine the kinds of food accessible to the birds. Crane flies and May flies occurred in large numbers and were eaten by many species of birds. Among the injurious insects upon which observations were made we may mention potato beetle, bean flea-beetle, tortoise beetles, cabbage worm, harlequin cabbage bug, 12-spotted cucumber beetle, pea aphid, tobacco worm, fall webworm, sawfly, locust leaf-mining beetle, flea-beetles, rose chafer, May beetle, cutworms, grasshoppers, ants, weevils, and oak scale. Observations made on insects injurious to farm crops indicated that birds are of little service in protecting farm crops against the attacks of injurious insects, and that they can not be depended upon for this purpose, but that insecticides must be used freely and repeatedly. Better service was rendered by birds in controlling the numbers of certain insects injurious to shade trees. Detailed notes are given on the relationship of birds to beneficial insects, such as honeybee, soldier beetles, tiger beetles, brown beetles, ladybirds, bees, and wasps. As a rule these beneficial insects were not fed upon to a great extent by the birds on the Maryland farm. Parasitic Hymenoptera, however, were eaten by 36 species of birds.

Considering the insect food of the 645 native birds of which the stomachs were examined, it was found that the birds were most insectivorous in May, when more than 90 per cent of the food consisted of insects. Throughout the entire period of observation insects furnished 60.41 per cent of the total amount of food eaten by the various birds. Of this amount beetles furnished the most, and white ants the least. Observations were also made on the feeding habits of the nestlings of grasshopper, sparrow, oriole, house wren, catbird, and other species. The greatest benefit from the presence of nestlings consists in their consumption of caterpillars and grasshoppers. Notes are also given on the destruction of poultry and game by crows, eagles, Cooper hawks, sharp-shinned hawk, and great horned owl. Mention is also made of the consumption of fish by certain aquatic species and the destruction of mice, rabbits, and carrion by various species of birds. Among the cultivated fruits the following were grown on the farm upon which the observations were made: Strawberries, cherries, grapes, tomatoes, melons, together with a number of wild fruits, including raspberries, elderberries, blackberries, mulberries, smilax, blueberries, wild cherries, etc. These fruits were eaten in varying quantities by the different species of birds. Notes are also presented on the distribution of seeds by birds, on the destruction of grain by crows, blackbirds, English sparrows, and other species, and on the destruction of weed seeds by native sparrows and other species. The bulletin also contains an annotated list of all the species of birds observed upon the farm.

As a result of the author's observations, it is concluded that at Marshall Hall the English sparrow, sharp-shinned hawk, and great horned owl are injurious and should be killed. The same is true of sapsucker, while the feeding habits of the crow present rather an unfavorable case for this bird. The other species of birds are believed to do rather more good than harm, under ordinary conditions.

The birds of Wyoming. W. C. KNIGHT (*Wyoming Sta. Bul.* 55, pp. 174, pls. 48, figs. 14).—The author presents an annotated list of about 300 species of birds observed in Wyoming. Brief notes are given on the habits and economic relations of the more important species. All of the illustrations for the bulletin are original.

The birds of North and Middle America, II. R. RIDGWAY (*Smithson. Inst., U. S. Nat. Mus. Bul.* 50, 1902, pt. 2, pp. XX + 834, pls. 22).—In this volume the author continues his descriptive catalogue of the birds of North and Middle America. The volume contains a description of the following families: Tanagridæ, Icteridæ, Cerebidæ, and Mnioiltidæ.

Handbook of birds of the Western United States, FLORENCE M. BAILEY (*Boston and New York: Houghton, Mifflin & Co., 1902, pp. XC + 512, pls. 36, figs. 601*).—This volume contains an account of methods of collecting and preparing birds' skins, nests, and eggs; a study of life zones; migration of birds; economic ornithology; bird protection; and local bird lists from different localities in Western States by various authors. The larger portion of the volume is occupied with a description of the birds commonly found in the Great Plains, Great Basin, Pacific Slope, and Lower Rio Grande. Keys are presented for the convenient identification of the various species.

Birds of the Rockies, L. S. KEYSER (*Chicago: A. C. McClurg & Co., 1902, pp. 355, pls. 8, figs. 39*).—In this volume the author presents a popular account of the common species of birds in the Rockies, with notes of their feeding habits and life history. A check list of Colorado birds, including nearly 800 species, is also presented.

Adirondack birds and their relation to forestry, E. A. STERLING (*Forestry Quart., 1 (1902), No. 1, pp. 18-25*).—Notes are given on the general relationship of birds to forestry. The woodpeckers, creepers, nuthatches, warblers, orioles, sparrows, thrushes, blackbirds, fly catchers, swallows, and crows and jays are considered to be most beneficial to forests on account of their feeding extensively upon injurious forest insects.

Some of the commonest birds in Egypt in their relation to agriculture, G. BONAPARTE (*Jour. Khediv. Agr. Soc. and School Agr., 4 (1902), No. 1, pp. 16-19*).—Notes are given on the feeding habits of a number of birds, including *Corvus cornix*, English sparrow, *Motacilla alba*, rock dove, *Galerita cristata*, *Coturnix communis*, *Ardea bubulcus*, etc. All of the birds mentioned are more or less insectivorous in their feeding habits, and are believed to do more good than harm to agriculture.

Insectivorous birds of Victoria, C. FRENCH (*Jour. Dept. Agr. Victoria, 1 (1902), Nos. 4, p. 403, pl. 1; 5, pp. 520, 521, pls. 2*).—Notes are given on the biology and feeding habits of *Malurus cyaneus*, *Artamus personatus*, and *Melanodryas bicolor*.

Index animalium, C. D. SHERBORN (*London: Cambridge Univ. Press, 1902, pt. 1, pp. LIX + 1195*).—In this work the author contemplates publishing an alphabetical list of the specific names applied to animals from January 1, 1758, to date. This part contains a list of the specific names from January 1, 1758, to December 31, 1800. The author has avoided any attempt to indicate synonymy among specific names, although the fact that the name of the genus stands opposite that of the species in each case serves as a sort of generic synonymy. The date at which the specific name was applied is fixed as nearly as possible in each case, and the title of the publication is also given in an abbreviated form. In the concluding portion of the volume an alphabetical list of the generic names is given, and under each genus are mentioned all of the specific names which were applied between 1758 and 1800.

METEOROLOGY—CLIMATOLOGY.

Monthly Weather Review (*Mo. Weather Rev., 30 (1902), Nos. 4, pp. 157-244, figs. 12, charts 9, map 1; 5, pp. 245-292, pl. 1, figs. 13, charts 8; 6, pp. 293-340, figs. 5, charts 8; 7, pp. 341-392, figs. 11, charts 8; 8, pp. 393-432, charts 8; 9, pp. 433-472, fig. 1, charts 8*).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of April, May, June, July, August, and September, 1902, recent papers bearing on meteorology, etc., these numbers contain the following articles and notes:

No. 4.—Special contributions on Studies on the Statics and Kinematics of the Atmosphere in the United States—IV, Review of Ferrel's and Oberbeck's Theories of the Local and the General Circulations (illus.), by F. H. Bigelow; Revision of Wolf's

Sun-spot Relative-numbers (illus.), by A. Wolfer; The Relation of the Sun-spot Cycle to Meteorology (illus.), by C. G. Abbot; and The Circulation of the Atmosphere in the Tropical and Equatorial Regions (illus.), by A. L. Rotch; and note on Jamaica Meteorological Service.

No. 5.—Special contributions on Studies on the Statics and Kinematics of the Atmosphere in the United States—V, Relations Between the General Circulation and the Cyclones and Anticyclones (illus.), by F. H. Bigelow; Annals of the Astrophysical Observatory of the Smithsonian Institution, Volume I, by S. P. Langley; The Winds and Rainfall of New Haven (illus.), by T. H. Davis; and A Mississippi Tornado, by S. C. Emery; and notes on meteorological conditions following the St. Vincent and Martinique eruptions, noises attending the eruption of Mount Pelee, dust storm and mud shower, and meteorological observations by travelers.

No. 6.—Special contributions on Hann's Meteorology, by F. H. Bigelow; Ground Temperature Observations at St. Ignatius College, Cleveland, Ohio, by L. J. Briggs; Unseasonable Weather in the United States, by E. B. Garriott; A Waterspout at Close Range, by O. L. Fassig; Studies on the Statics and Kinematics of the Atmosphere in the United States—VI, Certain Mathematical Formule Useful in Meteorological Discussions (illus.), by F. H. Bigelow; The First National Meteorological Congress of Mexico, by F. H. Bigelow; and Note on the Oscillation Period of Lake Erie (illus.), by R. A. Harris; and notes on apparatus for registering thunderstorms, lightning recorder, radio-active rain, laboratory work in physical geography and meteorology, sea temperature and shore climate, trees as forecasters of rain, meteorology in Argentina, dancing dervishes or dust whirls, the variations of the temperature of the free air at great altitudes, and halos, parhelic circles and contact circles (illus.).

No. 7.—Special contributions on Studies on the Statics and Kinematics of the Atmosphere in the United States—VII, A Contribution to Cosmical Meteorology (illus.), by F. H. Bigelow; The International Aeronautical Congress at Berlin, by A. L. Rotch; On the California Charts of Rainfall, by A. G. McAdie; and The Date Line in the Pacific Ocean, by J. Page; and notes on meteorology in Hawaii (see below), charting simultaneous observations, the season of vegetation, volcanic dust, and the variation of terrestrial gravity over the ocean.

No. 8.—Special contributions on Ocean Currents, by J. Page; Summer Meeting of the American Forestry Association, by A. J. Henry; The Permanency of Planetary Atmospheres, According to the Kinetic Theory of Gases, by S. R. Cook; and Text-books and Works of Reference for Students of Elementary Meteorology, by W. F. R. Phillips; and notes on experimental agriculture at meteorological stations, and mountain stations for meteorology.

No. 9.—Special contributions on The Rainfall in the City of Madras and the Frequency of Sun Spots (illus.), by M. B. Subha Rao; A Dark Day in Washington, by M. Eells; and Indian Summer; and notes on weather fixes train loads, a comparison with the barometric standard of Costa Rica, physics and meteorology, meteorology at the British Association, Belfast, September, 1902, Weather Bureau men as instructors in meteorology, John T. Probert, Heinrich Wild, and Senor Augustin M. Chavez.

Meteorology in Hawaii (*Mo. Weather Rev.*, 30 (1902), No. 7, pp. 364-369, figs. 5).—This is a very full abstract of an article by C. J. Lyons, territorial meteorologist, published in *Pacific Commercial Advertiser*, January 1, 1902. The history and present organization of the weather service in the Hawaiian Islands is explained and the climatology of the islands, especially with reference to the sugar industry and to health, is discussed. The wide variations in climatic conditions, particularly as regards rainfall in different parts of the islands, are illustrated by maps. The data reported show "that as to rainfall the islands have a great variety of climates. While some regions are almost rainless, others are deluged; and still others, like Honolulu, the chief place of resort, have a moderate rainfall only—the showers of an English

April with the temperature of an Italian June." A controlling climatic factor is the winds. "The prevailing winds are the northeast trades, at a temperature of about 70° F. and a saturation of about 65 per cent, but these are greatly modified by the mountain masses." These modifications are explained.

Studies on the statics and kinematics of the atmosphere in the United States, F. H. BIGELOW (*U. S. Dept. Agr., Weather Bureau Doc. 273*, pp. 62, figs. 29).—These studies are reprinted from *Monthly Weather Review*, 30 (1902), pp. 13, 80, 117, 163, 250, 304, 347, and deal with a new barometric system for the United States, Canada, and the West Indies; methods of observing and discussing the motions of the atmosphere; the observed circulation of the atmosphere in the high and low areas; review of Ferrel's and Oberbeck's theories of the local and general circulations; relations between the general circulation and the cyclones and anticyclones; certain mathematical formulæ useful in meteorological discussions; and a contribution to cosmical meteorology.

Report on the work of the Station of Agricultural Climatology of Juvisy during the year 1901, C. FLAMMARION (*Ann. Min. Agr. [France]*, 21 (1902), No. 2, pp. 395-421, figs. 14).—As in previous years (*E. S. R.*, 13, p. 627), observations were made on temperature of the air and of the soil at different depths, atmospheric pressure, humidity, rainfall, cloudiness, duration of sunshine and solar radiation, and underground waters, and also on the shedding and renewal of leaves, the action of solar rays of different colors on plants and animals (silkworms), and the influence of electricity on plants (see p. 548).

On the existence of a warmer current of air at an altitude of from 10 to 15 kilometers, R. ASSMANN (*Sitzber. Kgl. Preuss. Akad. Wiss. Berlin*, 1902, No. 24, pp. 495-504).

On some phenomena which suggest a short period of solar and meteorological changes, N. and W. J. S. LOCKYER (*Proc. Roy. Soc. [London]*, 70 (1902), No. 466, pp. 500-504, figs. 2).

Weather conditions, C. W. PETERSON (*Rpt. Dept. Agr. Northwest Territories*, 1901, pp. 5-24).—The organization of the weather service of the Northwest Territories is briefly explained and data for temperature, precipitation, hailstorms, and crop conditions for a large number of stations are given in tables and notes.

Rainfall in the agricultural districts of Queensland, C. L. WRAGGE (*Queensland Agr. Jour.*, 11 (1902), No. 3, p. 208).—This is a summary of observations at 41 different places in Queensland during the year ended July 31, 1902.

Meteorology (*Trans. and Proc. New Zealand Inst.*, 34 (1901), pp. 595, 596).—A summary is given of observations on atmospheric pressure, temperature, rainfall, wind movement, and cloudiness during 1901 and 37 previous years at Auckland, Wellington, and Dunedin.

Meteorology, P. BONÂME (*Rap. An. Sta. Agron. [Mauritius]*, 1901, pp. 1-8).—A summary is given of observations in Mauritius during the year 1901 on atmospheric pressure, temperature, humidity, and rainfall.

On the climate of Tunis, G. GINESTOUS (*Bul. Dir. Agr. et Com. [Tunis]*, 7 (1902), No. 25, pp. 413-429, figs. 5, charts 4).—This is the fourth communication (*E. S. R.*, 14, p. 124) on this subject and summarizes the available meteorological data for the three autumn months, September, October, and November.

Climatology of Poulo-Condore, G. LE LAY (*Bul. Écon. Dir. Agr. et Com. Indo-China*, n. ser., 5 (1902), No. 6, pp. 433-439, figs. 3).—Observations on temperature, pressure, rainfall, humidity, cloudiness, and wind movement during 1900 and 1901 at the meteorological station at Poulo-Condore, Indo-China, are reported.

Observations on thunderstorms and hailstorms in Steiermark, Kärnten, and Oberkrain, K. PROHASKA (*Mitt. Naturw. Ver. Steiermark*, 1901, No. 38, pp. 49-84, figs. 3).—A record is given of the occurrence of thunderstorms and hailstorms in these regions during 1900 and previous years, as well as of the damage caused by such storms.

WATER—SOILS.

Water, A. J. J. VANDEVELDE (*Het water, zijn nut en zijne geraren voor den mensch. Ghent: G. Van Doosselaere, 1902, pp. 23*).—A general discussion of properties and uses.

Six months' daily examination of Melbourne tap water, T. CHERRY (*Proc. Roy. Soc. Victoria, n. ser., 15 (1902), pt. 1., pp. 69-75*).—The methods and results of bacteriological examinations are given.

Sanitary analyses of some Iowa deep well waters, J. B. WEEMS (*Proc. Iowa Acad. Sci., 9 (1901), pp. 63-70*).—Analyses of samples of water from 20 different places in the State are reported and the sanitary quality of the different waters is discussed.

On the purification of drinking water by means of ozone, E. SUGG and A. J. J. VANDEVELDE (*Reprint from Tijdschr. Toegepaste Scheik. en Hyg., 6 (1902), No. 1, pp. 8*).

The chemical composition of sewage of the Iowa State College sewage plant, J. B. WEEMS, J. C. BROWN, and R. C. MYERS (*Proc. Iowa Acad. Sci., 9 (1901), pp. 70-80*).—Chemical examinations of the sewage at frequent intervals are reported. The determinations made include free and albuminoid ammonia, nitrite and nitrate nitrogen, solids before and after ignition, and oxygen consumed.

A consideration of the action of saline irrigation water, C. F. ECKART (*Hawaiian [Sugar Planters'] Sta. Rpt. 1902, pp. 24-74, 76-100, pls. 7*).—A series of lysimeter experiments to test the effect of saline water on soils and sugar cane is reported.

"Five large tubs of the same dimensions and capable of holding 250 lbs. of soil were converted into lysimeters as follows: Over the perforated bottom of each tub a strip of coarse linen and another of wire gauze were placed to prevent the carrying away of particles of earth in the drainage waters following irrigation. Fifteen pounds of black sand formed a porous layer about 2 in. thick at the bottom of each lysimeter and on top of this were placed 200 lbs. of soil. Underneath each tub a large galvanized-iron funnel was attached to conduct all drainage into a receiver, where it was caught for measurement and analysis. . . . Two pieces of sound Lahaina seed cane, each bearing 2 eyes, were planted in each lysimeter. . . . An excessive amount of irrigation water was applied weekly throughout the experiments, [one] lysimeter receiving fresh water and the other lysimeters receiving water containing 200 gr. of salt to the gallon. Both the amount of water applied per irrigation and its percentage of salt were made large to intensify the resulting action on the soil, which was determined by the analysis of the respective drainage waters."

To note the fixing power of the soils for different fertilizing materials, as well as the influence of salt on nitrification, 4 of the tubs received each 5 gm. of potash as sulphate and 5 gm. of phosphoric acid as double superphosphate. The nitrogen, 10 gm. for each tub, was applied in different cases as nitrate of soda, sulphate of ammonia, and dried blood. One tub received no fertilizer.

Data regarding the amounts of irrigation and drainage, the composition of the drainage water, and evaporation are reported and discussed in detail. The general conclusions reached are that salt in "irrigation water renders available large amounts of the lime, magnesia, and potash in the soil. Where the water is saline, over-irrigations are necessary to keep the salt from reaching harmful accumulations in the soil, consequently enormous quantities of lime and magnesia, and a very large amount of potash must be washed out with the salt. Under such conditions the soil will eventually become depleted as regards these elements and become unproductive, unless they are replaced in the land. Occasional liming is considered especially necessary when saline irrigation waters are used.

"The quantity of salt that may be contained in irrigation water without producing material injury to the cane varies to a large extent with the nature of the soil and

the volume of irrigation used per acre. The quantities and proportions of the ingredients, other than common salt, contained in irrigation water also influence in large measure the action of such water on the growth of cane.

"Cane planted in lysimeters grew apparently unchecked with its roots in contact with a soil water containing 195.75 gr. of chlorin to the U. S. gallon. Cane absolutely refused to grow where the percentage of chlorin in the soil reached 0.198, the soil containing 28 per cent of its weight of water.

"Cane in lysimeters irrigated to excess with water containing 200 gr. of salt to the gallon made an apparently normal growth. In other tests with the same amount of salt in the water, but where excessive irrigations were not applied, the cane died.

"In brackish irrigation water the quantities of lime and magnesia are usually rather high, the latter element being in excess of the former. If it were not for the fact that the lime of the soil is considerably more soluble than the magnesia, where saline irrigation is used the soil water would have an excess of magnesia over lime. The latter condition would be decidedly unfavorable to the growth of cane. As the lime is washed from the soil in greater quantities than the magnesia, it is necessary to apply the former element to the land to prevent the soil water from ultimately containing more magnesia than lime."

Water-holding power and irrigation of Hawaiian soils; the application of nitrate of soda; the accumulation of salt in Hawaiian soils, J. T. CRAWLEY (*Hawaiian Planters' Mo.*, 21 (1902), No. 8, pp. 358-363).—Observations on 7 different soils are reported which show that the amount of water in the soils when saturated in the field varied from 22.87 per cent to 29.61 per cent, while in the same soils saturated after being dug up the amount of water varied from 31.95 per cent to 39.9 per cent, showing "that in order to obtain the amount of water that any given soil will take up it must be saturated in the field." As a means of determining the amount of water which may be applied to a soil without waste it is proposed that determinations of the water content be made in the soil before irrigation and 5 hours thereafter, the difference between the two determinations being taken as the absorptive power of the soil. This, multiplied by 9,120, which is the number of gallons of water corresponding to each per cent of moisture in an acre of soil to a depth of 2 ft., gives the number of gallons of water which the soil will absorb.

Experiments are reported in which nitrate was applied before and after irrigation. "When nitrate was applied after irrigation there were 12 times as much nitrate in the first 6 in. of soil than when applied before the irrigation. In the above case a considerable quantity of nitrate of soda was lost through irrigation after putting on the nitrate, but practically all remained in the first 6 in. of soil, when it was applied after irrigation."

Observations on soils which were irrigated with water containing as high as 0.2 per cent of soluble salts show that there was very little accumulation of salt in the soils.

The reversion of superphosphate of lime in the soil, W. F. SUTHERST (*Chem. News*, 86 (1902), No. 2236, pp. 170, 171).—Observations on mixtures of superphosphate with calcium carbonate, magnesium carbonate, and limonite in varying proportions are reported which show that the process of precipitation or reversion "does not by any means take place instantly, many days elapsing before all the water-soluble phosphate is rendered insoluble, and that only when a large excess of the reverting agents are present—a state of things not always occurring." Magnesium carbonate proves to be the most active reverting agent, iron oxid being next, and calcium carbonate last. Since the soil generally contains more iron oxid than magnesium or calcium carbonate the soluble phosphate is in most cases precipitated chiefly as an iron compound. The author's investigations indicate, however, that it is only from the calcium and magnesium compounds that the root sap takes up phosphoric acid.

"The neutral or basic phosphatic manures, such as basic slag or basic superphosphate, are in the insoluble form already, and being combined chiefly with calcium, the greater part of the phosphoric acid is thus available for plant food; this being especially the case with basic superphosphate, the whole of whose phosphoric acid is soluble in citric acid solution."

Soil chemistry and bacteriology, J. G. LIPMAN (*New Jersey Stat. Rpt. 1901*, pp. 213, 214, pl. 1).—A brief statement of the proposed work of this new department of the station, with a description of a method of securing samples of soil for examination.

On the classification of soils, K. O. BJØRLYKKE (*Ber. Norges Landbr. Høiskoles Virks.*, 1901-1902, App. pp. 3-38, figs. 16).

FERTILIZERS.

Handbook of fertilizers, M. PASSON (*Handbuch des Düngewesens. Leipzig: M. Heinsius Nachfolger, 1902*, pp. X + 335).—The history of the use of fertilizers in ancient and modern times is traced; the composition of the plant and soil with reference to fertilization, methods of improving soils, and the nature and use of natural and artificial manures and fertilizers are discussed; and the methods of applying fertilizers to particular crops are explained. There is also a chapter devoted to the best means at the disposal of the farmer for determining the fertilizer requirements of his soils in which a simple sedimentation method of mechanical analysis, the author's apparatus and method for determining calcium carbonate (E. S. R., 13, p. 319), and a plan for plat experiments are described and the practical application of the results so obtained is briefly explained.

Phosphates, H. J. PATTERSON (*Pennsylvania State Dept. Agr. Bul. 94*, pp. 87).—A very full discussion of the sources and forms of phosphoric acid used in agriculture and their methods of preparation and application, based to some extent on compiled information, but largely on the author's investigations carried on at the Maryland Station for several years (E. S. R., 12, p. 930).

"All of the experiments which have been conducted upon the use of phosphoric acid in agriculture have given results which seem to warrant the general statement that much of the practice now followed in the use of phosphates is not founded upon facts. . . .

"There is no doubt but that the first step in the economical use of phosphates is to imitate nature and endeavor to keep the soil well supplied with organic matter; for it is only by such means that the phosphates contained in the soil naturally and those applied artificially can be fully utilized by the cultivated crops.

"It is very evident from all the tests cited that some crops, particularly the turnip family, have a greater ability than others to use crude or insoluble phosphates, and these experiments would certainly teach that the aim should be to employ such crops for rendering insoluble phosphates available and by such a practice save much that is now being spent for sulphuric acid and the cost of manufacturing the soluble phosphates.

"The experiments, in most instances, show that the presence of carbonate of lime is of considerable advantage in increasing the availability of phosphates.

"Some of the tests show that the iron and alumina phosphates are much more valuable as plant foods than is generally considered; in fact, under some circumstances they seem to be as soluble and even superior to lime phosphates.

"In regard to the so-called available phosphoric acid of commercial fertilizers, the results all point to the fact that there is no difference in it depending upon its source; that is, a pound of available phosphoric acid from a mineral source is just as valuable as a pound from an organic source. . . .

"The results of both field and plat experiments show that certain classes of phosphates are more available and hence have a higher agricultural value than would be given them by official methods of analysis. This condition would seem to warrant some modified method for analyzing such materials. This is particularly true of the tetra-phosphates when used on some soils."

Investigations relative to the use of nitrogenous materials, E. B. VOORHEES (*New Jersey Stat. Rpt. 1901, pp. 144-182*).—The investigations here reported are a continuation of those of previous years (E. S. R., 13, p. 727) and have in part been discussed in Bulletin 150 of the station (E. S. R., 13, p. 435). The composition of cow manure (mixed and unmixed solid and liquid) before and after being subjected to leaching and experiments with the different kinds of manure on oats followed by corn, without additional manure, are reported, the main purpose being to compare the availability of the nitrogen of the different kinds of manure with that of other fertilizing materials. Taking the nitrogen recovered by the crops as 100 in case of nitrate of soda, the relative availability observed was as follows:

Relative availability of nitrogen in different forms.

	Oats.	Oats and corn.
Nitrate of soda.....	100.00	100.00
Sulphate of ammonia.....	90.22	87.75
Dried blood.....	68.35	73.07
Solid manure, fresh.....	14.16	26.36
Solid manure, leached.....	9.67	21.99
Solid and liquid manure, fresh.....	40.10	51.46
Solid and liquid manure, leached.....	28.91	35.91

"It is quite apparent that in the residual effect considered, the availability of the manure, especially the solid manures, is increased very considerably. At the same time the availability of the nitrate and of the ammonia is decreased."

The availability of organic nitrogen in raw materials, J. P. STREET (*New Jersey Stat. Rpt. 1901, pp. 137-143*).—The solubility of nitrogen of 31 classes of materials in potassium permanganate solution, as determined by a method described in an earlier report (E. S. R., 11, p. 720), is reported and discussed. The average results obtained were as follows: Horn meal (1 sample) 95.9 per cent, ammonite (2 samples) 94.5, concentrated tankage (1 sample) 93.7, cracklings (1 sample) 93.5, dried blood (15 samples) 93, hoof meal (2 samples) 91, castor pomace (1 sample) 90, peanut pulp (1 sample) 89.3, pigeon manure (1 sample) 88.8, degelatinized bone (1 sample) 87.3, button bone (2 samples) 85.4, tankage (15 samples) 85.2, steamed bone (3 samples) 84.6, dissolved bone (2 samples) 83.1 and 62.7, dried fish (43 samples) 81.1, cottonseed meal (3 samples) 80.3, bone sawings (3 samples) 77.8, linseed meal (1 sample) 77.7, soft ground bone (1 sample) 71.6, wool waste (6 samples) 71.3, horse meat (1 sample) 70.4, raw bone (4 samples) 67.4, dissolved tankage (2 samples) 64.5, king crab (2 samples) 62.5, hair manure (1 sample) 54.6, burned garbage (1 sample) 51.5, garbage fertilizer (3 samples) 48.7, snuff sand (1 sample) 48.3, steamed leather (1 sample) 39.5, treated leather (1 sample) 33.4, raw leather (1 sample) 25.5 per cent. In case of dried blood the solubility ranged from 87.4 to 95.6, with an average of 93 per cent; dried fish from 56.1 to 92.9, with an average of 81.1 per cent; tankage from 65 to 93.2, with an average of 85.2 per cent.

A review of the investigations concerning denitrification (*New Jersey Stat. Rpt. 1901, pp. 183-210*).—A very complete review, which has been noted elsewhere (E. S. R., 14, p. 234).

Nitrate of soda in Africa, MAIZIÈRES (*L'Engrais, 17 (1902), No. 45, pp. 1070-1072, fig. 1*).—A brief discussion of the probable occurrence of extensive subterranean deposits of nitrate of soda in the region of the oasis of Touat, in Algeria.

New deposits of nitrate (*L'Engrais*, 17 (1902), No. 46, pp. 1095, 1096).—The occurrence of nitrate in Southern Algeria and in Death Valley, Cal., is briefly referred to.

On injury by perchlorate, B. SJOLLEMA and A. STUTZER (*Deut. Landw. Presse*, 29 (1902), No. 90, p. 733).—The question of the priority of discovery of the injurious effect of perchlorate on plants is discussed.

Fertilizing Hawaiian rice soils, J. T. CRAWLEY (*Hawaiian Planters' Mo.*, 21 (1902), No. 4, pp. 179-182).—This article describes the present practice of using no fertilizer or applying only shrimp meal, and discusses the fertilizer requirements of rice as indicated by analyses of the rice plant and of a number of Hawaiian rice soils.

Fertilizing in fall and winter (*Mitt. Deut. Landw. Gesell.*, 17 (1902), No. 44, pp. 267, 268).—A general discussion of the fall and winter application of lime and marl and phosphatic and potassic fertilizers.

Analyses of commercial fertilizers, M. A. SCOVELL and H. E. CURTIS (*Kentucky Sta. Bul.* 102, pp. 167-228).—The results of inspection of fertilizers during the spring of 1902, including analyses of 500 samples, are reported with brief explanatory notes. "The results of the analyses show that of the 500 samples analyzed, 55, representing 49 brands and 23 firms, fell so far below the guaranteed analyses in phosphoric acid, nitrogen, or potash, or any two, or all three of these ingredients, that the deficiencies could not be accounted for by variations in sampling or analysis. It is probable that in most cases variations can be accounted for by hurried or careless mixing at the factories, or gross mistakes in shipping one brand for another, but in one or two instances the results show a desire on the part of the manufacturer to guarantee a higher percentage of the essential ingredients than the goods contain. The great majority of the manufacturers, however, have furnished in most instances fertilizers fully up to guarantee."

Analyses of commercial fertilizers, W. L. HUTCHINSON (*Mississippi Sta. Bul.* 77, pp. 27).—Analyses and valuations of 345 samples examined during 1902 are reported.

Fertilizers (*New Jersey Stat. Rpt.* 1901, pp. 17-77).—A reprint of Bulletin 154 of the station (E. S. R., 13, p. 730) with addition of data regarding market prices of fertilizers in New Jersey during 1900 and preceding years, the text of the State fertilizer law, and lists of inspectors and of manufacturers whose goods were inspected during 1901.

Report of analyses of commercial fertilizers for the spring and fall of 1902, L. L. VAN SLYKE and W. H. ANDREWS (*New York State Sta. Bul.* 216, pp. 103-167).—The results of analyses of 446 different brands of fertilizers are reported. Of these, 309 were complete fertilizers in which the total nitrogen varied from 0.68 to 8.97 per cent, averaging 2.24 per cent; the water-soluble nitrogen from 0 to 5.72 per cent, averaging 0.93 per cent; the available phosphoric acid from 1.72 to 12 per cent, averaging 8.62 per cent; the potash from 0.55 to 13.33 per cent, averaging 4.67 per cent. In 50 out of the 309 brands examined the potash was in the form of sulphate free from excess of chlorids. The average amounts of nitrogen, available phosphoric acid, and potash exceeded the guaranteed averages by 0.32 per cent, 0.91 per cent, and 0.22 per cent, respectively. The average retail selling price of the fertilizers was \$26.14, the retail cost of the separate ingredients unmixed, \$20.76.

FIELD CROPS.

Annual report of the Alaska Agricultural Experiment Stations for 1901, C. C. GEORGESEN (*U. S. Dept. Agr., Office of Experiment Stations Rpt.* 1901, pp. 239-359, pls. 17).—This report deals with experiments in growing cereals and vegetables at the Alaska Experiment Stations and at numerous other points, together with the progress made in the improvement of the stations during 1901. In addition to this matter the conditions and agricultural possibilities of the Yukon Valley, the region

of the interior along the trails between Eagle and Valdez, the Fortymile country, the Tanana Valley, and the Copper River region are presented. Reports on the culture of field and garden crops by settlers at different points are given, and soil temperatures taken daily at various places for several years during the growing season, and meteorological observations at different points, for 1899 to 1900, inclusive, are tabulated.

Work at Sitka Station.—Swedish winter rye sown October 3, 1900, survived the winter and ripened September 15. Wheat sown at the same time did not live through the winter. Romanow spring wheat, which has given the best results in previous tests, was the only variety grown in 1901. Two plats of old ground were seeded May 8 and a plat of new ground May 11. The wheat on the old ground was harvested September 17 and the crop on the new ground October 3. The following varieties of barley were tested: Manshury, Sisolsk, Manchuria, Lapland, Black Hulless, and Chevalier. All of these varieties proved promising with the exception of Chevalier. Lapland was the earliest of the varieties grown. Black Hulless is not considered a very productive barley, but is recommended for its earliness and its value as a food material for the natives, being well adapted for this purpose on account of its naked kernels.

Of 2 varieties of oats under test, Burt Extra Early gave the best yield. This variety has proven one of the most promising and has never failed to mature. The other variety, North Finnish Black, did not mature satisfactorily and is not considered adapted to the region. The following quantities of fertilizing substances were applied per acre and compared in connection with growing North Finnish Black oats on new ground: 30 tons of seaweed, 30 tons of stable manure, 500 lbs. fish guano, 30 tons of seaweed plowed under and 500 lbs. of guano sown broadcast after plowing, and 30 tons of stable manure plowed under and 500 lbs. of guano applied broadcast after plowing. The oats were sown May 22 and on June 15 they ranked in appearance in the following order from the best to the poorest: (1) Manure and guano, (2) seaweed and guano, (3) manure, (4) seaweed, and (5) guano. The check plat, which had received no fertilizer, was the poorest. This relative rank was maintained throughout the season and the yields of hay obtained from the different plats were also in the same order. The yield on the check plat was practically nothing. "The experiment simply proves in an emphatic way . . . that new cleared and broken land is unproductive unless it is fertilized." The results of growing oats and peas as a mixture were quite satisfactory.

A plat of Orenborg buckwheat sown May 22 was ripe September 5. This variety and a so-called Finnish buckwheat can be grown successfully in Alaska, but Japanese and Silver Hull buckwheat have quite generally been failures. Flax on new ground was not a success. The results of vegetables on old ground were highly satisfactory, while on new ground they were practically failures. Seaweed was found to be an excellent fertilizer for potatoes, followed in productiveness by guano. The culture of raspberries, currants, and gooseberries was successful.

Work at Kenai Station.—Sisolsk rye was sown August 20, 1900, and harvested September 26, 1901. The plants grew from 5 to 6 feet high. At the close of the blossoming period the plants tillered profusely and much of the straw remained green up to the time of harvesting. Only about 50 per cent of the heads produced grain. Promising results were obtained with Sandomer and Yarasloff winter wheat. It is believed that on old ground and in ordinary seasons Yarasloff, the earlier of the two varieties, will mature. Sandomer showed a greater tendency to sucker. Several varieties of spring wheat were sown May 10 and 11, but owing to a drought the growing season was shortened and the crop was cut for hay September 6.

Manshury barley sown May 24 on old and new ground was harvested October 4. The old ground produced a uniform growth, while on the new ground the plants were quite uneven in height and threw up many suckers. At the time of harvest only the older heads were ripe. Beartown barley was grown on old ground from

seed raised at the station in 1899. When the plants were going out of bloom about August 15 they were quite uniformly 36 inches high. This is the earliest variety grown at the station. It has a tendency to lodge badly. Sisolsk barley, grown on the same kind of ground as Beartown, threw up numerous suckers and consequently produced a very uneven crop. The early heads had produced firm grains, while the suckers were still green when the crop was cut October 5. Permu, on the same kind of ground as the two preceding varieties and from seed grown at the station, had begun ripening by September 16 and was harvested on the same day with Beartown and Sisolsk.

Experiments were carried on with 9 varieties of oats, all of which were harvested from October 1 to 5. Burt Extra Early produced a large percentage of ripe plants, although new suckers were growing up all the time. White Russian, grown from seed produced at the station, stood up well and showed a good percentage of ripe plants at the end of the season. Siberian oats tillered very heavily when wet weather set in and ripened only the earliest heads. Improved Ligowa tillered less than any other variety and about 90 per cent of it ripened. Most of the grain of the Black Finnish variety was hard when harvested, but the straw was not all yellow. The straw of Tobolsk was also partly green, and about 75 per cent of the grain ripened. St. Petersburg, Zhelanni, and Banner ripened only a small percentage of their grain.

Orenborg buckwheat, although a partial failure, produced more seed than Silver Hull. Japanese buckwheat was a total failure. Ufa and Yarasloff spring emmer were retarded by drought and did not mature. Riga flax yielded very little ripe seed. A part of the crop came up later than the rest and set no pods, but the straw was fine and straight and the fiber exceedingly tough. Good stands of flat peas, red clover, and red and alsike clover mixed were obtained.

Potatoes were grown on the level ground and in raised beds, as practiced by the Russians in the Territory. The raised beds did not show any merit. The potatoes were planted May 18 and dug September 27. The yield was about eightfold, and from 60 to 70 per cent were marketable. Among the vegetables tested cabbage, peas, beans, rhubarb, asparagus, and turnips were grown more or less successfully.

Work at Rampart Station.—Spring rye, barley, oats, spring wheat, and clover were grown, and notes on these crops to about the middle of August are given. The principal facts in connection with these experiments are that fall sown rye made a healthy and vigorous growth the following spring and produced plump and perfectly matured grain by the beginning of August, and that barley sown the latter part of May matured seed by the middle of August. Among the garden crops tried lettuce, kale, peas, onions, and carrots made a good growth. Buckwheat and potatoes were killed to the ground by frost July 31. At this date the tubers from native seed potatoes were larger than the tubers obtained from other sources.

Annual report of the Hawaii Agricultural Experiment Station for 1901, J. G. SMITH (*U. S. Dept. Agr., Office of Experiment Stations Rpt. 1901, pp. 361-379, pls. 8*).—The official steps taken in connection with the establishment of the station are summarized, and the work done upon the station site in the way of land improvement, the construction of buildings, and in general the preparation for experimental work, is reported in detail. The condition of the coffee industry is described and directions for the culture of coffee are given. Potato, sweet potato, taro, rice, and cassia culture in the islands is briefly noted. The raising of ducks, chickens, and turkeys is mentioned, and the lines of inquiry of most importance are suggested.

Annual report of the Porto Rico Agricultural Experiment Station for 1901, F. D. GARDNER (*U. S. Dept. Agr., Office of Experiment Stations Rpt. 1901, pp. 381-415, pls. 5*).—The initial steps taken toward the establishment of the station are summarized, and the agricultural resources and capabilities of Porto Rico are discussed. In connection with the consideration of the soils and climate of the island, the results of mechanical analyses of Porto Rican soils, and subsoils made by

the Bureau of Soils of this Department, and the rainfall records from January, 1899, to December, 1901, are reported. The coffee, sugar, and tobacco industries are described, and statistics bearing on the subject are presented. The production of citrus fruits, alligator pears, mangoes, bananas, guavas, pineapples, cocoanuts, fiber plants, and a number of minor crops, is briefly noted. A description of stock raising on the island, including some statistics with reference to this industry and a note on insect pests, are also given.

Report of the agriculturist, E. R. LLOYD (*Mississippi Sta. Rpt. 1902, pp. 10-16*).—Thirty-two varieties of corn were tested in 1901 and the results obtained are briefly given, together with short descriptive notes for each variety. The results with 20 varieties of cotton, tested the same season, are also given. The application of 10 tons of barnyard manure increased the yield of seed cotton 304 lbs. per acre. The use of barnyard manure also had good effects on the yields of cowpeas and corn. Fall-sown wheat, flax, and alfalfa were winterkilled.

Report of Calgary Experiment Station, P. T. BONE (*Rpt. Dept. Agr. Northwest Territories, 1901, pp. 42-56*).—Variety tests with spring and winter wheat, oats, barley, spelt, rape, and potatoes are reported, and the culture of alfalfa, flax, and sugar beets is discussed.

Annual report on experimental farms and gardens in the Bombay Presidency (*Ann. Rpt. Expt. Farms and Gardens in Bombay Presidency, 1902, pp. 1-32*).—The results of culture tests with Australian saltbush, *Paspalum dilatatum*, *Sorghum vulgare*, Mauritius water-grass, Guinea grass, soy beans, rhea, cassava, sweet potatoes, maize, peanuts, *Pennisetum typhoides*, and sugar cane are briefly noted. The use of different fertilizers in connection with growing these crops is also described. In many instances the results of this season confirm the conclusions drawn the previous year.

Methods of conducting plat experiments, B. R. LARSEN (*Arbeidsregler for de spredte Akerreksforsog. Christiania: Johansen & Nielsen, 1902, pp. 27*).—Methods of conducting plat experiments at the Agricultural High School of Norway are outlined for the purpose of instructing experimenters cooperating with the institution.

Crop report for 1901 and 1902, F. G. SLX (*Dept. Land Records and Agr., Central Provinces, Season and Crop Rpt. 1901-2, pp. 1-11*).—Among other data statistical notes are given on the culture of *Audropogon vulgare*, *Cajanus indicus*, *Sesamum indicum*, *Cicer arietinum*, *Lathyrus sativus*, *Errum lens*, *Phaseolus mungo*, and *P. acuminatus*.

The effect of potash on plants, as shown in experiments with potatoes, tobacco, buckwheat, mustard, chicory, and oats, H. WILFARTH and G. WIMMER, (*Arb. Deut. Landw. Gesell., 1902, No. 68, pp. 106, figs. 14*).—The experiments here reported were conducted in the years 1896-1900, inclusive. The results obtained with the different crops for each season are tabulated in detail and discussed.

A soil mixture almost free from potash was used in the test. The potash applications were more effective in increasing the size of the plant organs containing the reserve material than in increasing the yield of the stems and leaves. This fact was especially marked in the case of potatoes and beets. Although an increase in the application of potash decreased the percentage of stems and leaves, it did not have a very marked effect on the roots. The influence of potash on the appearance and shape of the leaves was quite marked. The lack of potash manifested itself by a yellowish-brown color of the entire leaf, followed by spots or stripes located in the portions between the veins. These spots or stripes were also yellowish-brown, but much more intense than the rest of the leaf, and in some instances assumed a whitish appearance. The petiole of the leaf and the ribs retained their dark green color. The lack of potash was especially well shown in the leaf coloration of tobacco, buckwheat, and potatoes. The insufficiency of potash in the soil was also indicated by a characteristic curling of the leaves and by a sudden collapse of individual plants. The effects of insufficient supplies of nitrogen and phosphoric acid in soil differed

materially from those due to a lack of potash. Nitrogen in insufficient quantities was characterized by yellow leaves, and a lack of phosphoric acid by dark green leaves. Sugar beets grown in soil lacking either nitrogen or phosphoric acid remained small, but did not decompose, and also contained a normal percentage of sugar. A heavy application of nitrogen when potash was lacking reduced the percentage of tubers and seed and also the percentage of starch, as compared with results obtained from light applications under the same conditions. This was especially noticeable with potatoes and beets. The percentages in these tests were based upon the entire plant.

The quantity of water transpired per gram of dry matter produced was found to increase when potash was applied. This result is considered due to the check in plant growth as soon as the potash supply has been used up, in which case the production of dry matter is arrested, while the transpiration continues. The quantity of water transpired under normal conditions for each gram of dry matter produced by the entire plant, as determined in these experiments, was as follows: Potatoes 200 to 230, tobacco 300 to 370, buckwheat 400, mustard 500, chicory 400, and oats 460 gm.

The various potash salts used, with the exception of potassium nitrate, did not cause any marked differences in the results. With potatoes potassium sulphate and potassium chlorid gave practically equal yields, but the starch content of the tubers was in favor of the sulphate. The effect of potash on starch formation was studied, and the results obtained showed that for each gram of potash taken up by the plant potatoes produced 36 gm. of starch, buckwheat 31, and oats 29. The sugar content in beets was subject to greater fluctuations than the starch content in the other plants, the range being from 8 gm. of sugar for every gram of potash taken up by the entire plant when no potash was given to 25 gm. when sufficient potash was supplied.

The effects of insufficient potash, phosphoric acid, and nitrogen were also compared. A beet grown in soil lacking potash weighed 26 gm. and contained only 2½ per cent of sugar, while a beet grown in soil lacking phosphoric acid weighed only 14 gm. but contained 14 per cent of sugar, and one grown with insufficient nitrogen weighed 15 gm. and contained 17 per cent of sugar. Based on the dry matter in plants the sugar content was 2, 22, and 33 per cent for the beets grown on soil lacking potash, phosphoric acid, and nitrogen, respectively.

In studying the quantity of potash taken up by plants when present in more than necessary quantities it was found that the dry matter of the leaves of potatoes, tobacco, buckwheat, and mustard contained 5, 3, 2, and 3½ per cent, respectively. In the dry matter of sugar-beet leaves 5½ per cent of potash was found. In the seed and tubers the relation was found quite different. In the case of the greatest lack of potash the tubers of potatoes contained from 1.2 to 1.9 per cent of potash in the dry matter, the seed of tobacco 1.4 per cent, buckwheat 0.7 per cent, mustard 1 per cent, and oats 0.9 per cent. When the potash supply was increased, even until it reached a surplus, these figures were not increased to any great extent. Very large quantities of potash, however, caused a marked increase in the potash content of potato tubers, and in the case of chicory and sugar beets the potash content in the roots rose with the quantity of potash applied to the soil. Considering the total amount of potash taken up by the plant it is shown that without potash fertilization from 56 to 81 per cent occurred in the tubers, and when potash was applied in increasing quantities, the percentage rose to 93 but fell back to 70 when the application was in excess of the needs of the plant. In sugar beets receiving no potash from 10 to 20 per cent of the total potash taken up was found in the root, while in samples grown on a soil having received a normal supply it reached 44 per cent. Chicory contained 29 per cent of the total potash in the roots when no potash was applied and 77 per cent when a liberal application was made. The percentage of total potash of the plant in buckwheat and oats is quite constant, being 39 and 58 per cent, respectively, but an excess of potash in the soil caused a marked decrease. In the case of mustard the

figures ranged from 14 to 31 per cent and decreased to 13 per cent when potash was given in excess. The figures for tobacco varied greatly with the different varieties and were quite irregular. The average figures show that for each gram of potash potatoes, buckwheat, and oats contained 42, 79, and 49 gm. of starch, respectively. Sugar beets contained 150 gm. of sugar for each gram of potash and chicory 247 gm. of carbohydrates calculated to the starch equivalent. Tobacco seed contained 25 gm. and mustard seed 30 gm. of fat for each gram of potash. It is calculated from the results of these experiments that 0.51 kg. of potash is required for the production of 100 kg. of fresh potatoes, 4.2 kg. for 100 kg. of tobacco leaves, 0.103 kg. for 100 kg. of green mustard plants, and about 1 kg. for 100 kg. of dry matter in the entire oat plant.

Fertilizer tests on grass, barley, and swedes (*Bd. Agr. [London], Rpt. Agr. Education and Research, 1900-01, pp. 48-50, 58-72*).—Fertilizing pasture with high and low grade basic slag gave inconclusive results, and there was no apparent difference in the effect of the 2 kinds of slag on the character of the herbage. In the results from fertilizer tests with barley in 1900, it was observed that the influence of nitrogenous manure was most apparent and that phosphatic fertilizers together with sulphate of ammonia also increased the yield of grain. The effect of potash was very slight. In 1901 results indicated that when the yields of grain and straw and the malting properties of barley are concerned a complete mixture of commercial fertilizers is most profitable. The following is considered a suitable application: 1 cwt. sulphate of ammonia, 2 cwt. superphosphate, 2 cwt. kainit. With swedes the general results show that better crops were grown by mixtures of commercial fertilizers than by barnyard manure. Sulphate of ammonia and nitrate of soda are much more effective than either potash or phosphates in increasing the hay crop. In this connection the dangers of heavy dressings of nitrogenous fertilizers are discussed and cases are pointed out where clover was killed by the use of sulphate of ammonia or of nitrate of soda.

Experiments with phosphatic fertilizers on meadows and rye, REMY (*Deut. Landw. Presse, 29 (1902), Nos. 90, p. 729; 93, pp. 753, 754*).—The results of cooperative experiments with superphosphate, Thomas slag, and Algerian phosphate on meadows and rye are tabulated in detail and discussed. The results showed that in general phosphatic acid in finely ground Algerian phosphate is equal in value to phosphoric acid in the form of Thomas slag.

Alfalfa on Illinois soil, C. G. HOPKINS (*Illinois Sta. Bul. 76, pp. 311-349, figs. 9*).—Results of pot and field experiments are reported. The purpose of the experiments was to determine the value of furnishing the soil with different elements of plant food in alfalfa culture and to study the effect of inoculating the soil with bacteria which enable the growing alfalfa plant to use the free nitrogen of the air.

The observations showed that the bacteria which enable alfalfa to obtain nitrogen from the air are usually absent in Illinois soils, and that the crop for this reason is entirely dependent upon the soil for its nitrogen. Without the proper soil bacteria an exceedingly rich soil and liberal applications of nitrogenous fertilizers are required to produce good crops of alfalfa. Even the rich black prairie soil of Illinois lacked sufficient available nitrogen for maximum crops, and applications of available nitrogen produced yields of hay from 2 to 4 times as large as crops entirely dependent upon the natural supply of the soil. An experiment further showed that inoculated soil produced crops just as large as soil heavily fertilized with commercial nitrogen. On most soils, except limestone soils, the application of air-slaked lime as well as inoculation with bacteria has proved beneficial.

In studying the effect of the different plant food elements in the different experiments it was found that a complete fertilizer with lime gave better results than applications lacking in one element or lime. The maximum losses when either nitrogen, phosphoric acid, or potash were lacking were 3,200, 1,440, and 480 lbs. of hay per acre, respectively. The author considers these figures as fairly representative of the

relative values of the different elements of the soil under test. In the field tests air-slaked lime and bone meal were each applied at the rate of 320 lbs. per acre and potassium sulphate at the rate of 160 lbs. After inoculation the lime increased the yield of hay over no fertilizer by 1,020 lbs. per acre, and bone meal and lime together by 2,220 lbs. The total yields were 5,280 lbs. of air-dried hay from the unfertilized soil, 7,740 lbs. from the limed soil, and 10,000 lbs. from the soil which had received lime and bone meal.

The fixation of nitrogen by the bacteria was determined in both pot and field culture. The pot experiments indicated that on ordinary fertilized soil the alfalfa bacteria were capable of fixing 46.42 lbs. of nitrogen per acre. The dry matter of the crops from the uninoculated pots contained 2.59 per cent of nitrogen as compared with 3.62 per cent from the inoculated pots. The results of the field experiments were in perfect agreement with these results.

General directions for growing alfalfa are given and the present status of alfalfa culture in Illinois described.

Growing alfalfa in Kansas, H. M. COTTRELL (*Kansas Sta. Bul. 114, pp. 51-85, pls. 7*).—This bulletin is a treatise on alfalfa culture under Kansas conditions. The requirements of the crop are discussed and full directions for the different cultural steps are presented. Attention is also given to the curing and feeding of alfalfa. In treating the different subjects the author draws upon results obtained at different experiment stations.

Fertilizer and culture experiments with hops, A. D. HALL (*Bd. Agr. [London], Rpt. Agr. Education and Research, 1900-01, pp. 83-90*).—Cooperative fertilizer tests have been in progress for several years, and the detailed results of the work are here tabulated and general conclusions presented. It is stated that since the hop is an all-round feeder, the fertilizer application should contain all the elements of plant food. The results further point to the fact that the problem of manuring hops resolves itself largely into a study of the soil in order to determine the deficient elements.

In the culture experiments different methods of cultivation were compared. A plat of 24 hills, which for 7 years received no cultivation at all except the mere destruction of weeds by the lightest hoeing, yielded 150 lbs. of green hops, while 2 other plats with the same number of hills, one deeply cultivated and the other uncultivated, for one year gave each 146 lbs. The entire tract receiving no cultivation averaged 2,400 lbs. of dry hops per acre. In this case the manures were simply put on the surface of the soil.

Experiments with hops, REMY (*Deut. Landw. Presse, 29 (1902), No. 88, pp. 716, 717*).—Fertilizer experiments were conducted to test the relative efficiency of different potash salts. It was found that the concentrated potash salts obtained at Stassfurt are equally effective with the higher priced martellin. The author arrives at the conclusion that when the lower maturing leaves of the hop plant approach a minimum content of phosphoric acid at the beginning of the blossoming period, the soil is in need of that element. The nitrogen requirement of hops varied remarkably with the different varieties. The English varieties required much more nitrogen than the continental sorts. A report on the work of breeding hops is given, but the experiments have not been in progress long enough to show results.

Seed selection of oats, J. HUNTEMANN (*Deut. Landw. Presse, 29 (1902), No. 92, pp. 747, 748*).—Seed oats were separated by means of a centrifugal machine into 3 grades and compared in a culture test with unselected seed. It was found that the second-grade seed gave a better return than the first grade. In the variety under test a large percentage of grains had attached to them secondary smaller grains, and owing to the increased weight the centrifugal machine threw these combined grains into the heavier seed, although they did not really belong to that grade. This fact is given as explanatory of the small yield from the first-grade seed. The selection

of seed by means of the machine was found profitable. Notes on the culture of oats are also given.

Paspalum dilatatum (*Dept. Agr., Central Provinces, Bul. 7, 1902, pp. 3*).—Culture tests with *Paspalum dilatatum* on different soils are reported and its value for India discussed. The results of the experiments seemed to indicate that it is a fairly good forage crop for cultivation with slight irrigation or with good moisture-retaining soils.

Potato experiments in 1901, B. D. HALSTED (*New Jersey Stat. Rpt. 1901, pp. 388, 389*).—In connection with other work the effect on the yield of potatoes by mulching with shavings was observed. The relative numbers for the yield were 360 on mulched and 310 on unmulched soil, and the relative weights of the crop 91 lbs. for mulched land and 67.3 lbs. for unmulched ground.

Fertilizer experiments with rape (*Deut. Landw. Presse, 29 (1902), No. 95, pp. 768, 769, figs. 4*).—Rape was sown on sandy soil in August and harvested the following July. The normal applications of the various fertilizing substances used per hectare were as follows: 120 kg. of nitrate of soda, 200 kg. of Thomas slag, 75 kg. of 40 per cent potash salt, and 400 kg. of carbonate of lime. Much the greater gain was obtained from double these amounts of the different substances applied together. The nitrate of soda was applied in September, March, and April, one-third of the total quantity being given each time.

On cane sugar and the process of its manufacture in Java, H. C. PRINSEN-GEERLIGS (*Altrincham, Eng.: Office of "Sugar Cane," 1902, 2. ed. enl., pp. 106*).

Experiments with sugar cane, C. F. ECKART (*Hawaiian [Sugar Planters'] Sta. Rpt. 1902, pp. 3-24*).—Culture and variety tests with sugar cane are reported. Planting tests as described in a previous report (*E. S. R., 12, p. 1033*) were continued, and tables are given bearing on the weights of the cane, quality of juice, and yields of sugar of the various plats at the close of the experiment. The varieties grown in these tests, as in the previous ones, were Lahaina and Rose Bamboo. The different methods of planting, as determined by the average production of sugar for 1900 and 1902, ranked in the following order: (1) One eye per 12 in., (2) one continuous cane in row, (3) one eye per 6 in., (4) two continuous canes in row, and (5) one eye per 18 in.

In connection with the report on the variety tests, the difference in plant-food requirements of the different varieties is pointed out. Among new varieties White Bamboo and Demerara No. 74 were extremely promising. Otaheite and Salangore, 2 Louisiana varieties, did not give favorable returns. The results of the different varieties for 1900 are given in the abstract of the report for that year, and the results from the ratoons of 11 of these varieties harvested in 1902 are shown in the following table:

Results from the ratoon crop of different varieties of sugar cane.

Varieties.	Cane per acre.	Cane juice.			Sugar per acre.	Available sugar per acre.	Cane per ton of available sugar.	
		Density.	Sugar content.	Purity coefficient.			Plant cane, 1900.	Ratoons, 1902.
	Pounds.		Per cent.		Pounds.	Pounds.	Tons.	Tons.
Lahaina	108,029	19.98	18.40	92.09	17,706	15,393	7.7	7.0
Yellow Caledonia	130,970	18.88	15.50	84.32	17,930	15,071	10.1	8.6
Yellow Bamboo	148,394	16.11	14.10	87.52	18,233	15,478	9.0	9.5
Fiji Purple	112,384	18.22	16.10	88.36	16,228	13,845	9.8	8.1
Big Ribbon	133,294	18.38	15.50	84.33	18,275	15,230	11.1	8.7
Striped Singapore	153,531	19.45	17.80	91.52	24,350	21,104	7.8	7.2
Louisiana Purple	130,680	18.45	16.80	91.05	19,759	17,085	8.9	7.6
Louisiana Striped	149,556	19.18	17.50	91.24	23,585	20,419	8.3	7.3
Louisiana Tibboo Mild	187,018	18.03	15.90	88.19	27,061	23,064	8.5	8.5
Demerara No. 95	163,005	19.52	17.50	87.60	25,184	21,896	7.6	7.6
Demerara No. 117	171,336	18.57	16.20	87.23	24,946	21,283	10.2	8.0

The composition of the cane and of the different parts of the plant, the mineral matter and nitrogen taken out of the soil, and the quantities of nitrogen, phosphoric acid, potash, and lime used per ton of sugar grown are given in tables for each variety.

Chlorids in tobacco. W. H. PEGRAM (*Abs. in Science, n. ser., 17 (1903), No. 418, p. 28*).—The work set forth in this paper was designed and is being prosecuted for the purpose of ascertaining whether there is a relation between the chlorids in tobacco and the chlorids in the fertilizer used in its production; also whether a high percentage of chlorids (as calcium and magnesium chlorids) affects the hygroscopic property of tobacco, giving abnormal and damaging results at certain stages of its preparation and manufacture. The data are insufficient as yet to justify a valid conclusion.

Experiments with wheat at Grignon in 1902. P. P. DEHÉRAIN and C. DUPONT (*Semaine Agr., 22 (1902), No. 1121, p. 355*).—Of 5 different varieties Japhet produced the largest yield of grain, 50.1 quintals per hectare, followed by Massy with a yield of 43.1 quintals. The latter variety produced the largest yield of straw, 97.6 quintals per hectare. The yields of all varieties, owing to favorable moisture conditions, were quite large. The fertilizers were applied broadcast and in drills and the results were slightly in favor of the drill application.

HORTICULTURE.

Report of the assistant in horticulture, A. T. JORDAN (*New Jersey Stat. Rpt. 1901, pp. 215-268*).—The author gives the results of another year's experiments to determine the effect of irrigation and the relative effects of fertilizers with and without irrigation upon the early and total yields of asparagus, blackberries, raspberries, strawberries, currants, and gooseberries. A similar report was given in 1900 (*E. S. R., 13, p. 738*). A further study of the value of an additional amount of 200 lbs. of nitrate of soda for some of these crops has been made and variety and fertilizer tests conducted with plums, cherries, dwarf and standard pears, and peaches. Tests of some newer varieties of bush fruits and of subirrigation experiments with them are also recorded, together with tests of a number of varieties of vegetables, of large *v.* small tomato seed, and of early and late starting for tomatoes. A table showing the daily and monthly precipitations for the year is included.

In the experiments with asparagus Palmetto yielded 33 lbs. more of early stalks and 1,512.7 lbs. more of total cut than any of 5 other varieties tested. The early yield was largest in every instance on the unirrigated plats, while in 3 out of 4 cases the total yield was largest on the irrigated plats. The total results of 4 years, during which the experiments have been under way, show a greater cut of early asparagus from the unirrigated plats than from the duplicate irrigated plats. The total cut, however, has been slightly larger from the irrigated plats. The advantage shown in the earlier years of the experiment from setting large selected crowns of asparagus has now entirely disappeared. The yields obtained by applying barnyard manure at the rate of 20 tons per acre have been greater than from the use of 500 lbs. of complete commercial fertilizers applied in the spring, or from 300 lbs. of bone and potash applied in the fall with 500 lbs. of complete commercial fertilizers applied in the spring, or from these same commercial fertilizers plus 200 lbs. additional of nitrate of soda applied at the time of cutting.

With blackberries the early yield during the 4 years of the experiment has averaged 22 per cent better on the irrigated than on the unirrigated plats, and the total yield 13.3 percent better. The effects of the different fertilizers have been irregular. In 1901 Early Harvest gave by far the largest early yield of 6 varieties tested, as well as the largest total yield. Eldorado stood a close second as to total yield, but produced scarcely a third as large early yield as Early Harvest.

The yields obtained from irrigated plats of raspberries for 4 years have been but little larger than those obtained from unirrigated plats. The various fertilizers used have given conflicting results, but are quite uniform in showing no advantage from the supplemental amount of nitrate of soda (200 lbs. per acre). Turner was the heaviest yielding red raspberry and Souhegan was the best black raspberry tested in 1901.

With currants irrigation has increased the yield on an average for 4 years of over 15 per cent. The yield on the irrigated plats was lowest where nitrate of soda was used.

Gooseberries during a period of 4 years have been increased a little over 7 per cent in yield by irrigation. The heaviest yields have been obtained on plats fertilized with stable manure.

In the test with strawberries Bubach gave the largest early yield (1,441.9 qt.), with Glen Mary second (1,325.5 qt.). In the total yield Glen Mary led with 8,783.7 qt., followed by Bubach with 7,572.9 qt. per acre. Of the early sorts Excelsior was most productive in 1901, with Darling second. Sample was one of the heaviest yielding late varieties. In 1901 the unirrigated plats led in yield in all cases except early yield on one plat. During 4 years irrigation has been beneficial in slightly increasing the early yield only. Unirrigated plats fertilized with complete commercial fertilizers supplemented with nitrate of soda at the rate of 200 lbs. per acre have produced the largest early yield and the largest total yield. A fertilizer made up of bone, potash, and phosphoric acid has given the largest yield under irrigation. Relative to the culture of strawberries in hills *v.* matted rows, it is stated that beyond question some varieties are better adapted to hill culture than others. Nineteen varieties in 1901 gave greater returns from hill culture than from matted rows. In 1900 but 11 varieties gave increased yields in hill culture. Some of the most productive varieties in hills are Margaret, Ideal, Bubach, Glen Mary, Hall Favorite, and Seaford.

Experiments with plums, pears, peaches, and cherries have not yet been conducted long enough to warrant any definite conclusions. The yields obtained on different plats and with different varieties are noted as a matter of record. In a test of the Stringfellow method of setting peaches, as compared with the usual method, the Stringfellow trees taken as a whole have given yields much lower than those set in the usual way. The following data show the set of fruit in 1901 on peach trees that had been thinned in 1900:

Set of peaches on thinned trees.

	Number of fruits.		
	Tree 1.	Tree 2.	Tree 3.
Removed in thinning, 1900.....	599	272	216
Picked ripe in 1900	263	580	533
Total set, 1901	1,964	1,338	1,444

The table indicates the largest set of fruit on the tree that had been most severely thinned the preceding year.

Some experiments on the subirrigation of raspberries, currants, and gooseberries by plowing out a deep furrow, placing tile in this and planting the fruit over the tile, have been conducted now for 4 years, but have not given satisfactory results. In only 2 instances have the subirrigated plats given better yields than the controls. The difficulties of keeping the line of tile open are thought to be too great to render the use of tile for subirrigation of these fruits practicable.

In the test of garden beans Fillbasket Wax was the earliest maturing sort grown and Jones Stringless Wax the most productive. In comparisons of pole and dwarf Lima beans there has not been found much difference in earliness of maturing, but

in amount of early fruit and total yield the pole sorts were considerably ahead. Alaska was one of the best early smooth peas grown. The percentage of total weight of peas that are edible was determined for 29 varieties. This varied from 33 per cent in Ameer to 57 per cent in Admiral. Next to Admiral the varieties giving the largest percentage of edible peas were Quality, Nott New Perfection, Surprise, Premium Gem, and Heroine.

With tomatoes, Hulsart Selection was the earliest maturing variety in 1901. Best of All showed the smallest percentage of culls and stood third in lowest percentage of rotten fruit. Over $\frac{3}{4}$ of the total yield of Early Dwarf Prolific graded as culls and 53.4 per cent of Early Bird was culls. A test was made of large *v.* small tomato seed. Fifty of the largest and 50 of the smallest well-formed seed of Beauty were selected and planted in pots in the forcing house each spring for 3 seasons. The average weight of early tomatoes from the large seed for 3 seasons has been 7 lbs. 15 oz., and from small seed 5 lbs. 7 oz. The total weight from large seed has been 29 lbs. 15 oz., and from small seed 29 lbs. 8 oz. The average size of the fruit has been 4.8 oz. for the large seed and 4.9 oz. for the small seed. The weight of the culls has been about the same in both cases, while the weight of the rotten fruit in the case of the large seed was 2 lbs. 12 oz., and from the small seed 1 lb. 13 oz. The weight of the 50 large seeds when planted was 0.176 gm. and of the small seed 0.071 gm. In another experiment tomatoes were started February 1 to 15, March 1 to 15, and April 1, and handled all the way from 5 times in the case of those planted February 1 to twice with those planted April 1. The best yields were obtained from those started February 15 and the next best from those started March 1. These results indicate, in the opinion of the author, that the latter half of February is the best time to start tomato seed. Thus started they require handling 3 or 4 times.

Experiments in crossing plants, B. D. HALSTED (*New Jersey Stat. Rpt. 1901, pp. 389-411, pls. 8*).—In continuation of previous work (*E. S. R.*, 13, p. 743), plants were grown during the year from seed obtained in crossing Lima beans, tomatoes, cucumbers, eggplants, sweet corn, and salsify. The characteristics of the plants obtained, yields secured, etc., are recorded in considerable detail.

Beans (pp. 389-392).—In the case of beans the Henderson and Burpee types of dwarf Limas were crossed in 1900 and the seed obtained from these crosses planted in 1901. Of the hundreds of plants grown, all remained true to the dwarf type except 7 plants, which developed into vigorous climbing pole beans. The quality of the crossed beans compared favorably with the Burpee variety and was superior to that of the Henderson. The beans were not quite as large as those of the Burpee variety. The average yield was 27 pods per plant, five-sixths of which matured. This yield was about 4 times greater than that of the parent plants. In earliness the hybrid beans were ahead of the Henderson. Other experiments with wax beans indicate that this crop can be successfully grown continuously on the same ground under good cultivation for at least 8 years with 2 crops each season.

Tomatoes (pp. 392-396).—The crossing of yellow and red varieties of tomatoes in previous years resulted in producing plants of remarkable vigor. One of these plants produced fruits that were nearly seedless. When the seed of this plant was grown in 1901 an average crop of fair-sized fruits having a small percentage of seeds was produced. When Golden Sunrise, a yellow tomato, and Dwarf Champion, a red tomato, were grown alongside of each other the fruitfulness of the Golden Sunrise averaged 91, while that of Dwarf Champion averaged but 61. The Dwarf Champion came into earlier bearing than Golden Sunrise, and if green fruits be excluded from the record there would not be much in favor of the Golden Sunrise variety. The tomatoes in this experiment made the eighth crop grown continuously on the same land. The experiment brings out the fact that tomatoes may be successfully grown on the same land continuously if good tilth, spraying, and the prompt removal of diseased fruits are attended to.

Cucumbers (pp. 396-398).—The third generation of crossed cucumbers was grown in 1901. The original cross was White Spine upon White Pearl. The 1901 crop was not uniform, the fruit varying exceedingly in color, size, and form. One of the main purposes of the original cross was to remove the spines from the fruit. This was accomplished on some fruits, while others were remarkably rough. A plate is given showing 17 fruits, all differing from one another.

Eggplant (pp. 398-400).—In 1900 the New York Improved Spineless eggplant was crossed upon Long Purple. Plants obtained from the seed of this cross were grown in 1901. They were remarkably vigorous. The fruits were of good color, form, and size, and especially well suited for slicing. The quality was excellent. The fruits matured nearly a month earlier than the New York Improved, and 6 weeks in advance of Long Purple. This cross is considered very promising.

Sweet corn (pp. 400-408).—In the experiments with sweet corn the pink, white, and black grains obtained in crossing Egyptian, a white variety, with Black Mexican have been planted. The resulting ears have had mixed grains in every instance, but when pink grains were planted they constituted the largest percentage of the grain on the resulting ears; likewise black grains predominated on the ears when black grains were planted, and white grains when white seed were planted. It was observed in these experiments that the largest number of 8-rowed and 12-rowed ears were obtained from 10-rowed seed, 10-rowed ears from 8-rowed seed, and ears having more than 10 rows from seed having from 12 to 14 rows. Nothing was gained by starting corn indoors and setting it in the field when the plants were 4 weeks old. When pollen was prevented from reaching the silks of the ears the silks grew to an unusually large size and remained green 2 or 3 times longer than the normal period. Good ears were obtained by inbreeding, but the corn thus treated matured much less rapidly than corn grown in an open field. The inbred corn reproduced the peculiarities of the stock.

In another experiment corn was bred with the object of increasing its prolificness. Seven ears produced on 3 stalks were taken for seed. From this seed 144 stalks were grown. Of these 44 bore large single ears, 83 bore 2 marketable ears each, and 17 bore 3 or more ears each. It is stated that the number of stalks bearing 2 and 3 ears each were much larger in this plat of selected corn than in other plats of corn in which the seed was not selected with regard to prolificness.

Some further notes are given upon salsify hybrids, particularly as regards the color of the flowers produced. Nothing definite as regards the edibility of the roots obtained is reported. Other crosses mentioned are those of 2 species of *Martynia*, an unsuccessful cross of the trumpet creeper upon *Martynia*, a successful cross of the ordinary field flax (*Linum usitatissimum*) with the ornamental species (*L. grandiflorum*?).

Plant breeding and improvement in our experiment stations, B. D. HALSTED (*New Jersey Stat. Rpt. 1901*, pp. 411-419).—A brief review is given of the plant-breeding work conducted at each of the experiment stations up to the present time.

Apparent exceptions to the Mendel law of dissociation in hybrids, C. CORRENS (*Ber. Deut. Bot. Gesell.*, 20 (1902), No. 3, pp. 159-172).—The author presents some experimental data showing that Mendel's law does not appear to hold between crosses of black sugar corn (*Zea mays coerulesodulcis*) and pop corn (*Z. mays leucoceras*).

Experiments with salad plants, B. D. HALSTED (*New Jersey Stat. Rpt. 1901*, p. 419).—Swiss chard was sown May 13 and again July 28. Both lots grew well, but the early chard was somewhat affected with leaf blight while that sown later was nearly free. This result is in accord with that of earlier work of the station, which indicates that the blight does not flourish on late-sown chard. Plants of Swiss chard removed to the greenhouse in the autumn furnished leaf stalks through the winter and were again planted out in the spring, where they made a fine early

growth. New Zealand spinach has been successfully transplanted from the greenhouse and also grown from seed. The plant thrived through the hottest weather, producing an abundance of leaves. This is considered an excellent salad plant and worthy of more attention.

Culture of vegetables, E. YUNGE (*Ber. K. Lehranst. Wein, Obst u. Gartenbau, Geisenheim, 1901*, pp. 86-91, fig. 1).—Results secured in the culture of a large number of vegetables are briefly reported, together with notes on the wintering of vegetables.

Experiments on the use of commercial fertilizers for market gardening in 1901, J. AEBY and E. HEGH (*Rev. Gén. Agron. [Lourain], 11 (1902), No. 7-8, pp. 342-364*).—The experiments here reported have been under way for 2 years. The results obtained in 1900 have been previously noted (*E. S. R.*, 13, p. 849). The results of 1901 are in entire accord with those of the preceding year, and indicate that for market garden crops the most valuable results are obtained when commercial fertilizers are employed to supplement barnyard manures.

Experiments in onion growing at Dominica (*Agr. News [Barbados], 1 (1902), No. 14, p. 213*).—At the agricultural school at Dominica, in the West Indies, seedling onions gave a larger and more even crop than sets. The latter, however, were found easier to grow. Tenerife seed was used. The first sowings of the seed came up well, but later seedlings germinated badly, and in some instances scarcely any grew.

New way to transplant (*Pacific Coast Fruit World, 14 (1902), No. 11, p. 15*).—Description of a new method of moving trees. It consists essentially of a steel basket made up of 14 shovels of $\frac{5}{16}$ -in. plow steel. These are hinged to a steel platform surrounding the tree. The shovels are driven into the ground around the tree and the whole tree lifted by screw power.

The Russian apple and its outcome; behavior in the Northwest, A. T. ERWIN (*Rural New Yorker, 61 (1902), No. 2752, p. 717*).—Notes on the culture of hardy apples in the Northwest. Patten Greening is stated to be one of the most satisfactory varieties thus far originated for the Northwest.

Cold storage of apples, F. W. RANE, H. H. LAMSON, and F. W. MORSE (*New Hampshire Sta. Bul. 93, pp. 65-88, figs. 2*).—The authors have investigated the keeping qualities, prices, value of wrapping, and chemical changes of apples in cold storage, and the keeping qualities of apples when taken out of cold storage.

In 1899 apples were sent to Boston November 20 to be put in cold storage. At monthly intervals thereafter until July 11, 2 barrels of the fruit were examined and the number of firsts, seconds, and thirds counted. No extra precautions had been taken in preparing the apples and they were believed to fairly represent the ordinary condition of fall-purchased apples. The figures given indicate that apples of this sort can not safely be allowed to remain in cold storage after April, since they rapidly decay after that date. Even with more carefully picked and assorted apples the experiments of the following season showed that the apples were at their best only up to about April 15. The prices obtained for this fruit when sold on commission varied from \$2.57 to \$3.10 per barrel net. The fall market prices for apples ranged from \$1.25 to \$2.00 per barrel. Under the conditions of the experiment it paid well for putting them in cold storage.

A table is given showing the range of prices for apples for each of the months from November 1 to May 1 for the years 1896 to 1900. These indicate satisfactory profits from cold-storage apples.

Six barrels of apples were sent to each of 2 cold-storage systems in Boston to test the relative merits of cold air and brine in apple storage. The apples in each case were examined at different periods from February 5 to July 11. Up to April the figures given do not show much difference in the keeping quality of the apples under the 2 different systems of storage, but after that date there was a slightly greater loss under the brine system.

In an examination of the apples in the different parts of the barrel to determine where the greatest amount of decay occurred, 33½ per cent of the decayed fruit was found within 6 in. of the headed end.

In order to test the general impression that fruit does not keep well when taken out of cold storage, 150 apples were taken out of cold storage each month from February to May and placed in 3 trays of 50 each. Two trays were placed in green-houses having temperatures of approximately 70 and 55° F., respectively. The third was placed in a cool cellar having an approximate temperature of 40°. The apples did not touch each other in the trays and were not covered. These apples were observed and a record kept of their condition. The average time it took for all the fruit to become spotted under the 3 temperatures given was about as follows: Warm temperature, 13 days; medium, 32 days; cellar temperature, 40 days. The following conclusions are drawn from this experiment:

"The length of time that apples keep when taken out of cold storage is in direct proportion to the height of the temperature they are subjected to. Cold-storage apples taken out during the spring months, if kept in a relatively cool place, will keep much longer than if allowed exposure to the ordinary temperatures. Cold storage simply retards decay, and when the fruit is taken out at a time when conditions are so much more favorable for decay, the fruit decomposes faster than in the fall or winter when the temperature is low."

Part of the data given on the influence of cold-storage in the decay of apples and on the effect of wrapping apples in paper has been previously reported (E. S. R., 13, p. 352). Further work along the same line was carried out by packing Baldwin apples in bushel boxes and placing them in cold storage in Boston. Four control boxes were placed in the station cold storage, the average temperature of which was 40-45° from November 1 to the middle of April, 45-50° from the middle of April to the middle of May, and 50-65° from the middle of May until July 1. The average temperature of the apples in the Boston cold-storage system was 34°. When the apples were examined January 2, those in the Boston storage were still perfect, while 4 per cent of the station stored apples showed decay. Examinations in March and April showed over 35 per cent more sound apples in the Boston cold storage, and the June examination showed 69 per cent more sound apples than in the station cold storage. As regards wrapping apples, it was found that the wrapped apples kept considerably better than the unwrapped, particularly during the latter months of storage; but little difference was noticed until March 1.

Tables of analyses are given showing the variation in composition with reference to invert and total sugar and acid in apples for several months after picking, during each of the years 1898 to 1901. The differences in composition between hand-picked apples and windfalls are also shown. From these data it is shown that "chemical changes take place within the apple which are independent of decay, and result in the over-ripe condition recognized by 'mealy' pulp and lack of flavor. Low temperatures hinder the chemical changes, while high temperatures hasten them. Apples intended for cold storage should be carefully handled and placed in the storehouse as soon as possible after picking."

Experiments in preserving winter fruits in peat, E. YUNGE (*Ber. K. Lehranst. Wein, Obst u. Gartenbau, Geisenheim, 1901, p. 75*).—Various sorts of apples were packed in peat direct. The peat had been sifted and was perfectly dry. The fruit thus treated kept in good condition, while that stored in the usual manner spoiled. When the fruits packed in the peat were rusty they acquired a disagreeable taste, while those with smoother skins were normal. It is recommended, therefore, that rusty fruits be first wrapped in paper before packing in peat. It is further recommended that fruit taken out of the peat be used up as rapidly as possible and that no more be taken out than can be used at once.

The culture and manufacture of tea in British India and Ceylon, with reference to its value for the tea culture of the Dutch Colonies, A. SCHULTE (*Beihefte Tropenpflanzer*, 2 (1901), No. 2, pp. 117, fig. 1, *dgms.* 5).—The author visited British India and Ceylon, and made a careful study of tea culture in those countries. The report includes a discussion of the history of tea culture; also a discussion of the botany, climate, soils, planting, cultivation, harvesting, and manufacture of tea.

Examination of wilted tea leaves for astringent matter showed 12 per cent in the bud and first leaf, $8\frac{1}{2}$ in the second and third leaves, 5 in the fourth and fifth leaves, and $3\frac{1}{2}$ in the old leaves. Examination of the fresh leaves as picked for manufacture in 2 different factories showed $10\frac{1}{2}$ and 11 per cent, respectively, of astringent material. The same leaves after rolling contained 16 and 17 per cent, and the finished tea 7 and 12 per cent, respectively. These figures indicate that the percentage of astringent material in the tea was considerably increased by rolling but decreased by subsequent oxidation.

Three varieties of tea grown at an elevation of 450 meters showed an average astringent content of $8\frac{3}{4}$ per cent; grown at an elevation of 2,000 meters the astringent content averaged $11\frac{1}{4}$ per cent. While a better quality of tea is thus produced in the higher altitudes, a greater quantity is produced on the same area on the lower lands.

Further experiments were made to determine whether the change in color from green to yellowish brown, the development of the aroma, and the decrease of astringent matter with the accompanying decrease of bitter content were due to the work of micro-organisms or to oxidation. The leaves were found to acquire the desired yellowish-brown color at a temperature of 35 to 40° C. The acid content of the leaves increased considerably during the rolling process, but decreased again during the oxidation process. Several different samples of tea leaves were sprayed with different strength solutions of acetic acid before rolling, for the purpose of preventing the development of fermentation bacteria. The presence of the acid in the leaves was found to delay oxidation, but not to prevent it. Further study is necessary before definite conclusions can be stated regarding the chemical changes which take place in the tea during fermentation.

The book of the strawberry, E. BECKETT (*London and New York: John Lane, 1902, pp. 83, pls. 4, figs. 7*).—This is the ninth of the series of Handbooks of Practical Gardening, edited by H. Roberts. Besides a very satisfactory presentation of cultural methods for strawberries, it includes directions for the culture of raspberries and blackberries, including the Loganberry. While some of the methods of English strawberry culture differ considerably from American methods, the work nevertheless contains many suggestions regarding propagation, culture, forcing, etc., which will be found useful to American strawberry growers.

Self and cross pollination, R. GOETHE (*Ber. K. Lehranst. Wein, Obst u. Gartenbau, Geisenheim, 1901, pp. 62-64, fig. 1*).—Further work is reported on the number and color of seeds obtained in crossing certain varieties of pears and apples. The shape of the seed is illustrated in some instances. The work is in continuation of that reported last year (*E. S. R.*, 13, p. 746).

Study of grape seeds, A. BONNET (*Ann. École Nat. Agr. Montpellier, n. ser., 2 (1902), No. 2, pp. 73-134, pls. 3, figs. 3*).—A comprehensive study of the seeds of grapes with reference to the identification of the various species, hybrids, and varieties of both American and European grapes. Good illustrations are given of the seeds of nearly all of the varieties described.

Report of the viticultural station at Eibingen, R. GOETHE ET AL. (*Ber. K. Lehranst. Wein, Obst u. Gartenbau, Geisenheim, 1901, pp. 26-56, pls. 2, figs. 9*).—This report covers work in grafting grapes, rooting grape cuttings, and growing both in the nursery. The percentages of plants that grew, using various species of grapes as stocks, are tabulated. Other matters reported upon are the yield and quality of grapes obtained in the station vineyard, forms of pure species of *Vitis* and various

hybrids, culture of new hybrids, preliminary notes on the ripening of 1-year-old wood, and the injurious effects of pruning on the growth of the tree trunk. The average thickness of the trunks of a large number of trees pruned in the pyramidal form was 8.4 cm.; pruned only by removing dead and crossed branches, 9.7 cm. The following year the pruned trees attained a diameter of 9.5 cm. and the unpruned trees 11.7 cm. Contrary to the usual belief that regular pruning serves to make stockier trees, these experiments indicate that strong pruning prevents the rapid growth of the stem rather than furthers it.

The carob tree, A. GUYADER (*Bul. Dir. Agr. et Com. [Tunis]*, 7 (1902), No. 25, pp. 430-453).—Detailed account of the nature, culture, composition, and uses of the carob tree and its products is given, its varieties are described, and the production in different countries noted. The fruit of the carob tree is used primarily as a stock food, but sometimes for human consumption. A sherbet is made from it by the Turks, and it is also used in some European countries as an adulterant of coffee.

English pleasure gardens, ROSE S. NICHOLS (*New York: The Macmillan Co.*, 1902, pp. XXIV+324, pls. 66, figs. 185, plans 10).—Popular descriptions of classic, monastic, mediæval, Tudor, Elizabethan, Stuart, Italian, eighteenth century, and modern gardens and grounds. A bibliography of the works of 170 different authors treating of the various kinds of gardens noted above is included.

The book of climbing plants, S. ARNOTT (*London and New York: John Lane*, 1902, pp. XIV+124, pls. 6).—An English book on climbing plants, in which the characteristics, culture, and value of the various annual, hardy deciduous, hardy herbaceous, and hardy evergreen climbers, hardy wall shrubs, climbers for growing under glass, roses, and clematis are popularly discussed. The book is the tenth in the series of Handbooks of Practical Gardening, edited by H. Roberts.

The book of old-fashioned flowers, H. ROBERTS (*London and New York: John Lane*, 1901, pp. 111, pls. 9).—A popular account is given of the old-fashioned hardy flowers grown in the cottage gardens of England. The garden is described with reference to the flowers growing in it during each of the 4 seasons of the year. In the latter part of the book brief chapters on soils, manures, seed sowing, etc., are given. The book is the fourth in this series of Handbooks of Practical Gardening.

A plea for hardy plants, J. W. ELLIOTT (*New York: Doubleday, Page & Co.*, 1902, pp. 76, figs. 52).—"This book has not been written to teach the art of landscape gardening, but the need of it." It is believed that \$1 intelligently spent on the grounds about the house will afford more beauty than \$10 spent in the house. Detailed plans are given for flower gardens and for laying out city and suburban lots of various sizes. The art in gardening and the beauty in hardy plants are brought out in the numerous illustrations, which constitute one of the chief features of the book.

Collection of Haarlem flowers (*Florilegium Harlemense. Haarlem: De Erven Loosjes*, 1901, pls. 60, descriptive text).—This work is published under the auspices of the council of the Algemeene Vereeniging voor Bloembollencultuur of Haarlem. It includes descriptions and life-sized colored illustrations of the bulbous and tuberous rooted plants of the Haarlem export trade. The book is published in 1 volume in the 4 languages, Dutch, English, French, and German.

A new hybrid poppy, F. CAYEUX (*Rev. Hort. [Paris]*, 74 (1902), No. 2, pp. 525-528, figs. 3; *abs. in Amer. Gard.*, 23 (1902), No. 415, p. 783, figs. 3).—A prolific, many-branched, yellow-flowered poppy (*Papaver pilosum*) was crossed on *P. bracteatum*, a poppy bearing large single red flowers, for the purpose of increasing the flowering capacity of the latter. When *P. pilosum* was used as a mother plant no seed was obtained, but when *P. bracteatum* was used as a mother plant a few seed were found. Out of a dozen plants grown from this seed, 3 plants with pale orange-red flowers, and intermediate in form between the two parents, have been found and given the name *P. piloso* by *bracteatum*. The parents and hybrid are illustrated. Three other

plants obtained had a much more dwarfed form and resembled neither parent. The author's experience with hybrid poppies is stated to differ from that of Gordon in that the individual plants of the first generation of hybrids differed widely from each other instead of being fairly uniform, as has been the case in Gordon's work.

Experiments with phloxes and their allies, B. D. HALSTED (*New Jersey Stas. Rpt. 1901, pp. 422-424*).—Lists are given of phloxes, cobaeas, gillias, and polemoniums grown. It was noticed that the phlox plants as they grew older contained many green forms. These plants had flower clusters with the bracts much prolonged and oval-shaped. The corollas were with long tubes and the lobes not fully expanded, giving a half open appearance to the bloom.

Experiments with ornamental plants, B. D. HALSTED (*New Jersey Stas. Rpt. 1901, pp. 421, 422*).—Notes are given on the following plants grown at the station: Chrysanthemums, peonies, Japanese redbud, hibiscus, cannas, nasturtiums, mignonette, petunias, and verbenas. A hardy type of chrysanthemum which has been grown at the station for several seasons was this year attacked for the first time by a rust. Japanese redbud has proved too tender for the cold winters and hot summers prevalent in New Jersey.

Experiments with lawn grasses, B. D. HALSTED (*New Jersey Stas. Rpt. 1901, p. 421*).—Nine plats of lawn grass were seeded at the station in 1896. A record is given of the percentages of the different grasses for each of the years up to 1901 for each plat. The highest percentages of the original grasses sown are found in the Rhode Island bent grass, Kentucky blue grass, and wood meadow grass (*Poa nemoralis*) plats.

FORESTRY.

The Western hemlock, E. T. ALLEN (*U. S. Dept. Agr., Bureau of Forestry Bul. 33, pp. 55, pls. 12*).—An attempt is made to remove the prejudice which has hitherto existed toward the Western hemlock (*Tsuga heterophylla*) by pointing out its uses, economic value, and conditions under which it may be grown, lumbered, and manufactured. This timber has suffered severely on account of the poor reputation given to its eastern relative. The wood of the Western hemlock is far superior to that of the eastern tree and is suitable for all uses in ordinary building, for paper pulp, for wooden ware, and particularly adapted to indoor finishing. The bark, which is abundantly produced, contains half as much again of tannin as that of the eastern tree. Under favorable conditions it reproduces abundantly and grows very rapidly.

The Western hemlock is found from Alaska to California, and in the northern portion of its range as far east as Montana. It seldom occurs as pure forest, but is usually associated as a mixture with red fir, spruce, cedar, and in northern California with redwood. The conditions favorable for the reproduction of hemlock are not those which are advantageous for most of the associated species, and it is probable that hemlock will reforest cut-over lands when red fir would fail to establish itself. This tree frequently attains a diameter of 8 ft. and a height of 250 ft., although as a rule the mature trees are from 3 to 5 ft. in diameter. It is very tolerant of dense shade and germinates and grows readily under conditions which its associated species would not tolerate.

The principal enemies, both fungus and insect, are described, after which the value of the wood for various uses, its durability, defects, etc., are shown. Tables are given showing the value and yield of first and second growth hemlock in a number of localities, and a brief statement given relative to the value of the bark as a source of tanning material. A list of the trees of Oregon and Washington, which are associated with the Western hemlock, completes the bulletin.

The hardy catalpa in commercial plantations, W. L. HALL (*U. S. Dept. Agr., Bureau of Forestry Bul. 37, pp. 1-48, pls. 23*).—Attention is called to the value of the

hardy catalpa (*Catalpa speciosa*), and 4 commercial plantations, all of which are situated in Kansas, are described at considerable length. The methods of planting, cultivation, and management are given, the soils described, and the rate of growth, products, and value are shown. Among the more important notes from the standpoint of the culture of this tree, it is shown that the hardy catalpa reaches its best growth only in very rich soils. In poor, sandy soil one of the plantations described has given no return, while in deep, rich loam it has given a clear annual profit of \$21.55 per acre.

When grown in pure forest or mixed with trees no taller than itself the catalpa should be protected by shelter belts of taller trees. If a large number of trees are to be planted it will be found cheaper to grow them from seed than buy them from a nursery. The trees should be closely planted, 4 by 4 ft. probably giving the best results, and thinned and pruned as required. The cutting back of the young trees after 2 or 3 seasons' growth, and the training up of a single sprout from the stump, greatly hastens the height growth and prevents side branches on the lower part of the trunk. When the first growth of the plantation is for any reason bushy and undesirable, a better growth can be secured by cutting the stand clean and reproducing it by sprouts. The best growth of catalpa has not been obtained in pure plantations, but so far in the Middle West only the osage orange and Russian mulberry have been found adapted to planting with the hardy catalpa. A high percentage of straight limbless poles can be secured only with the most careful treatment. The tree has a tendency toward crookedness and branching, which requires close attention to correct.

Eucalypts cultivated in the United States, A. J. McCLATCHIE (*U. S. Dept. Agr., Bureau of Forestry Bul. 35, pp. 106, pls. 91*).—The purpose of this bulletin is to give information concerning the characteristics of a number of species of Eucalyptus, their climatic requirements, and their uses, together with the directions and suggestions as to their propagation and culture. Means are also furnished for the identification of seedlings and mature trees so that specimens growing throughout the Southwest may be readily identified. At the present time, throughout the southwestern United States the eucalyptus trees are planted more extensively than any other exotic forest tree. Their adaptability for shade, windbreaks, fuel, timber, etc., makes them probably more valuable than any other forest tree planted on this continent. In the bulletin only those species which attain a diameter of over 1 ft. and a height of 40 to 50 ft. are discussed, and only those species which have fruited are treated. The author believes that when the merits of these trees are more fully understood, they will be planted more extensively as a covering to the treeless portion of the semitropic portion of the United States and will serve to furnish fuel, timber, and many other useful products.

A history of the lumber industry in the State of New York, W. F. Fox (*U. S. Dept. Agr., Bureau of Forestry Bul. 34, pp. 59, pls. 19*).—The primitive forest and its composition is described, after which the development of the lumber industry is traced. The first sawmills are said to have been established in 1623, the machinery for which was brought from Holland. The early methods of lumbering are described, after which, in considerable detail, the more modern methods are reviewed. Notes are given on the volume of lumber business, the profits of the industry, and the lumber markets of New York.

Report of the superintendent of forests, W. F. Fox (*New York State Forest, Fish and Game Com. Rpt. 1900, pp. 20-44, 97-155, pls. 11, figs. 3*).—A report is given on the forest reserves of the State and the various investigations incidental to the care, custody, and control of the forest lands owned by the State in the Adirondack and Catskill regions. The forest reserve belonging to the State amounts to 1,370,928 acres, embraced in more than 5,000 separate lots. Under the present law the scientific management of these forests is not properly provided for, and suggestions are

given for the modification of the law. In connection with the Bureau of Forestry of this Department the working plans have been made for a number of tracts. As a portion of his duties the State forester is obliged to collect statistics on the forest products of the State. These are given in detailed and tabular form.

A detailed report is also given on the forest fires occurring during 1900. During that season more than 14,000 acres were burned over, the loss of timber destroyed being estimated at \$12,400. Other losses bring the total up to about \$20,000.

A study in practical reforestation, J. Y. MCCLINTOCK (*New York State Forest, Fish and Game Com. Rpt. 1900, pp. 87-96, pls. 7*).—In connection with proposed silvicultural investigations to be carried on by the State forestry department, the author visited a number of places where forest-tree planting has been undertaken and reports at considerable length on the plantation made in the Stephen Girard estate, situated in the watershed of Lost Creek, in Schuylkill County, Pennsylvania. On this tract a series of plantings has been made, beginning with 1881. About 1,200 acres have been planted, the principal species being European larch, hardy catalpa, Scotch pine, white pine, black cherry, and Douglas spruce. In all, about 250,000 trees have been planted, the different plantings being described in some detail. The native species of trees have been protected and the estimated income derived from the entire tract is a little in excess of 4 per cent upon the cost of the industry.

A forest working plan for township 40, Hamilton County, New York, R. S. HOSMER and E. S. BRUCE (*New York State Forest, Fish and Game Com. Rpt. 1900, pp. 157-236, pls. 11, maps 4*).—This is a reprint of Bulletin 30 of the Bureau of Forestry of this Department (E. S. R., 13, p. 458).

Culture experiments with foreign trees in Austria, A. CIESLAR (*Ueber Anbauversuche mit fremdländischen Holzarten in Oesterreich. Vienna: Wilhelm Frick, 1901, pp. 55*).—Notes are given on the distribution, characteristics, and culture relations of a large number of exotic species of trees, most of which are of American origin. Among those described are the following: Douglas, Sitka, blue, Engelmann's, and white spruce; Port Orford cedar; Pacific arbor vitae; juniper; Japanese larch; white, Bank's, and pitch pine; balsam fir; red, bur, and pin oak; black walnut; butternut; Shagbark and bitternut hickory; sugar and silver maple; white ash; wild black cherry; and paper birch.

The woodman's handbook, I, H. S. GRAVES (*U. S. Dept. Agr., Bureau of Forestry Bul. 36, pp. 148, figs. 15, map 1*).—The purpose of this handbook is to give a collection of tables and rules of practical use to lumbermen, foresters, and others interested in the measurement of wood and timber. Only such information is given as is deemed of immediate practical value to American woodsmen. The unit of measure most commonly used in this country is the board foot, and tables are given based upon that system of measurement. Tables are given for the measurement of standing trees, the volume tables for such species as have been worked out in this country being included. The various methods of estimating standing timber are described and the essentials for a forest working plan are outlined. Special instruments useful to the woodsman are figured and their uses described.

Methods of estimating and measuring standing timber, A. KNECHTEL (*New York State Forest, Fish and Game Com. Rpt. 1900, pp. 67-86, pls. 4, map 1*).—About a dozen methods for the estimation of the amount of standing timber are described, and the advantages and weaknesses of each pointed out.

Wood, G. S. BOULGER (*London: Edward Arnold, 1902, pp. 369, pls. 4, figs. 66*).—This is a manual of the natural history and industrial applications of the timbers of commerce. After describing the origin, structure, and development of wood, the author gives keys for the recognition and classification of different kinds of woods. The various defects and diseases to which wood is subject are described and suggestions given relating to the selection, seasoning, storage, and durability of different kinds of timber. The various sources of wood supply are described as well as the

present methods for testing timber. The sources, characters, and uses of the principal woods of commerce are described, about 750 different kinds being enumerated. A bibliographical appendix is added giving the most important sources of information.

Forest reserve manual (*U. S. Dept. Int., Gen. Land Office, Forest Reserve Manual, 1902, pp. 97, figs. 2*).—General information is given relative to the object of forest reserves and their utilization, and the present organization for the protection and control of the forest reserves is described. The duties of the various forest officers are defined and instructions given for the care and propagation of the forest. The various forms of applications and permits for grazing, timber cutting, irrigation structures, etc., are given, and the penalties for violation of the rules are stated. While containing much information of general interest, the manual is intended primarily for the guidance of forest inspectors, rangers, and other officers.

SEEDS—WEEDS.

The germination of seed as affected by sunlight, V. JODIN (*Compt. Rend. Acad. Sci. Paris, 135 (1902), No. 10, pp. 443, 444*).—A series of experiments was conducted by the author, in which seeds were placed in vessels and covered with screens of different colors. Others were sealed in tubes and placed in similar situations. A report is given of seeds of cress which were placed in tubes, as described above. Under the conditions of the experiments all the seeds which had not been thoroughly dried lost their germinative power, falling from 100 per cent to 0 germinations within 2 months. If the tubes were opaque or completely transparent, the resistance of the seed seemed to depend more upon the heat action than the illuminating action of the sun's rays. Seeds dried and placed in a tube with a small quantity of phosphoric acid had a germination of 92 per cent in March, 1896. This tube was exposed continuously to the sun's rays until August 4, 1902, at which time 69 per cent had retained their vitality.

Observations on the duration of the germinative property of seeds, J. POISSON (*Compt. Rend. Acad. Sci. Paris, 135 (1902), No. 6, pp. 333-335*).—A number of instances are cited in which the germination of seeds has apparently been suspended for a number of years. In one case an annual species of *Lathyrus*, which had at one time been very abundant in a park, seemed to have entirely disappeared on account of the increased shade furnished by the trees. After about 30 years of dense growth the trees were thinned and the leguminous plant reappeared. Another instance cited is that of the occurrence of *Juncus bufonius* in 2 pots filled with soil taken at a considerable depth in an excavation made in a part of Paris. Another instance is the appearance of alders in great abundance on ditch banks in a tract of land which had been drained and on which, so far as known, no alders had ever been grown, nor were any known to exist anywhere in the vicinity from which the seed could have come.

The preservation of the germinative power of seeds, L. MAQUENNE (*Compt. Rend. Acad. Sci. Paris, 135 (1902), No. 3, pp. 208, 209*).—A study is reported on the effect of drying on the germination of seeds. The amount of moisture lost by seeds of castor bean, parsnip, radish, and wheat, when subjected to the temperature of a drying oven, as well as the loss when kept in a vacuum, are shown. It was found that seeds retained their germinative faculty much longer when thoroughly dried and kept in a vacuum than when exposed to the open air.

Report of the section of seed control, A. VOIGT (*Bot. Mus. u. Lab. Waarenkunde Hamburg, Ber. Abt. Samencontrole, 1901, X, pp. 11*).—A report is given of the activity of the seed control station in connection with the botanical laboratory, Hamburg, for the year ended June 30, 1901. During the period covered by this report 2,273 samples of seed were investigated, an increase of about 25 per cent over the previous

year's work. The principal investigations were for the presence of dodder seed, and purity and germination tests. Red, white, and alsike clover, serradella, alfalfa, and various species of grass seed formed the bulk of all the seed investigated. The investigations for dodder showed the presence of varying quantities of seed of that parasite in about 38 per cent of all the specimens examined. A detailed report is given showing the maximum, minimum, and average purity and germinative ability of the different kinds of seed tested, and also the variation from the percentages obtained the previous year. Some of the special seeds investigated are discussed in detail.

Report of the seed control station at Hernösand, C. G. STROMBERG (*Ber. Verks. Frökontrollanst. Hernösand, 1901, pp. 15*).—A report is given showing the maximum, minimum, and average vitality, purity, and intrinsic worth of 684 samples of seed tested between July, 1900, and June 30, 1901. The principal seeds were those of cereals, grass and forage plants.

Report of the seed control station at Luleå, 1900-1901, P. HELLSTRÖM (*Ber. Verks. Kem. Värthiol. Anst. Frökontrollanst. Luleå, 1901, pp. 33-38*).—A report is given on 234 analyses of seeds and upon the certification of 355 kilos of timothy seed. The results of the different analyses are shown in tabular form, the maximum, minimum, and average purity and germination being given. A report is also given of the weed seeds which were found most abundant in seed of rye, wheat, oats, timothy, and vetch.

Report of the seed control station at Molkom, 1901, J. A. ANDERSSON (*Red. Verm. Frökontrollanst. och Kem. Lab. Molkom, 1901, pp. 1-20*).—Detailed reports are given of tests made on 436 lots of seed which were tested during the year. In addition to the usual report of purity and germinations of the several samples, tables are given showing the average purity, vitality, etc., for all seed tests made since 1893 to the date of the report. The principal weed seeds and the relative amounts which were found present in grass and forage plant seed are shown, as well as the results of tests on the relative value of seed obtained from different countries, effect of treating seed for smut prevention, etc.

A study of dodders, B. D. HALSTED (*New Jersey Stat. Rpt. 1901, pp. 451-457, pls. 2*).—During the winter a study was made of a number of species of dodder, the seed of which were collected from clover, flax, and other seed. The germination of the dodder was determined and its subsequent growth ascertained. Compiled notes are given regarding different species of dodder and the plants which they attack.

Experiments with weeds, B. D. HALSTED (*New Jersey Stat. Rpt. 1901, p. 420*).—In continuation of the experiments previously reported (*E. S. R.*, 13, p. 756) the present status of the weed plot is described. At the present time brome grass, field bindweed, and yellow daisy have become very aggressive, while some reported previously have dropped from the head of the list and others have almost totally disappeared. A number of new weeds have appeared, and there seems to be a tendency for the ground to be covered with a growth of low plants such as clovers, grasses; and bindweeds, above which is a cover of tall growing plants such as sweet clover, yellow daisy, smartweed, and velvet leaf.

DISEASES OF PLANTS.

Report of the botanist, B. D. HALSTED (*New Jersey Stat. Rpt. 1901, pp. 385-459, pls. 13, fig 1*).—During the period covered by this report less attention has been given to the subject of plant diseases and their control than in previous years and more to the breeding of various varieties of plants. These are noted elsewhere. Observations have been continued on the asparagus rust and the usual work reported on weed investigations. Some studies were made on various species of dodder and these are reported at some length. The experiments with turnips, which have been carried on for 7 years, have been terminated, as it is fully demonstrated that lime is a satis-

factory remedy for the club root and that turnips do not thrive as a continuous crop for many years. Experiments for the control of potato scab have been continued, but on a considerably reduced scale. The results thus far obtained have not been uniform and while sulphur gave promise of value, before final judgment is rendered the tests need to be carried on upon a number of different kinds of soil.

The experiments with spraying were limited almost entirely to the use of soda-Bordeaux mixture with the same formula as that used in the previous report (E. S. R., 13, p. 756). The tomato diseases were of so little consequence that but little difference was noted in the sprayed and unsprayed plats. A leaf spot of chard due to *Cercospora beticola* developed to a considerable extent, and spraying with soda-Bordeaux reduced it to a considerable degree. Plats of cucumbers, chard, and ornamental plants were sprayed with kerosene emulsion to test its value as a fungicide, but the results obtained do not indicate that it has a value in checking the blights to which these plants were subject.

An experiment was carried on to determine whether Paris green could be used with the soda-Bordeaux mixture, the fungicides being applied to potatoes, eggplants, squashes, cucumbers, and beans. Each plat was treated 3 times at intervals of 10 days without harmful results, although the Paris green was added in a much higher percentage than is commonly employed. During the season covered by the report observations were made on the asparagus rust and attempts were made to ascertain its distribution throughout the United States. By means of letters sent to different stations it was found that this disease extends from New England to the Dakotas and south to Texas. As a rule there is an apparent decrease in the amount of asparagus rust, which is attributed to the fungus parasites of the rust and the more extensive cultivation of resistant varieties. Upon the college farm at the station the variety Palmetto was found to be comparatively free from rust. The variety Argenteuil is also quite resistant. It is claimed that the rust was more abundant on the west than on the east side of the plats, and it is suggested that this was due to the quicker drying of the dew on the side toward the morning sun.

The investigations on pear blight have been terminated on account of the change in ownership of the orchards on which the spraying and pruning were being carried on. The results for the different years' treatment are reviewed and summarized. Brief notes are given on ergot on different species of grass, on corn smut and cucumber blight, grape mildew, tulip mold, and fungi as related to weather.

The occurrence of clover broom rape is mentioned and the plant described. The species present was *Orobanche minor*. *O. ramosa* was also found attacking a tomato plant on the experiment station grounds.

In continuation of the investigations described in the previous report (E. S. R., 13, p. 757) a study was made on dimorphism of buckwheat, the third generation of the plants seeming to show that there was a tendency for the pistillate form to exert some control over the progeny.

Plant diseases observed during 1901, E. MARCHAL (*Bul. Agr. [Brussels]*, 18 (1902), No. 2, pp. 228-230).—Brief notes are given on the smut of cereals, potato scab, bacterial rot of potatoes, fairy rings, cherry diseases, and pear blight.

A report on cotton disease in Egypt, F. FLETCHER (*Jour. Khediv. Agr. Soc. and School Agr.*, 4 (1902), No. 3, pp. 122-126).—A preliminary report is given of a disease of cotton which was called to the attention of the author in 1902. Upon visiting the infected region he was informed that the disease had been noticed since 1898, and that it made its appearance where Sea Island cotton seed from America had been planted. The disease is believed to be of American origin, and reappears each year, the fungus being capable of remaining in the soil from year to year. The symptoms are briefly described, and various suggestions given for possible means of combating the disease. The author believes it is what is known in this country as sore shin, but the rapid wilting of the plant seems to indicate that it differs from that disease as usually described.

A disease of potato stems in Ohio, due to *Rhizoctonia*, A. D. SELBY (*Abs. in Science, n. ser., 16 (1902), No. 395, p. 138*).—For some time past investigations have been in progress at the Ohio Experiment Station upon the *Rhizoctonia* disease of potatoes. During June of 1902 a well-marked outbreak of this disease was reported at several points within the State. The affected plants show local areas of decay, both above and below the soil line. The most striking feature of the disease is the characteristic rosette aspect of the central leaves of the plants attacked. By the slight incurling of the leaves the affected plants may be readily recognized. This characteristic seems to be quite constant to a number of varieties.

Observations on the foot disease of wheat, L. MANGIN (*Jour. Agr. Prat., n. ser., 4 (1902), No. 36, pp. 306-308*).—Notes are given on a disease of wheat to which the name "piétin" is given. This disease has been known in France for more than half a century, and has recently been ascribed to attacks of *Ophiobolus graminis*, which is said to occur as a parasite on the wheat plant quite near the ground. Associated with this fungus are others, of which *Leptosphaeria herpotrichoides* is the most common. The author has conducted a number of experiments to determine the parasitism of these fungi, and both were found to be parasitic, but their rôle in the development of the disease is quite independent. The *Ophiobolus*, only in exceptional cases, causes the lodging of the grain, while on the other hand the *Leptosphaeria* is quite commonly the cause of the breaking down of the plants. Suggestions are given for the prevention of these diseases, the principal means being the treatment of the seed with fungicides and the selection of resistant varieties, the latter method seeming to offer the most satisfactory results.

The results of the hot water treatment of oats and spring wheat for smut prevention, H. ROMMETIN (*Jour. Agr. Prat., n. ser., 4 (1902), No. 39, pp. 407, 408*).—A brief note is given on the effect of hot water treatment on the eradication of oat smut. In fields which had from 8 to 12 per cent of their spikelets attacked by disease, when this seed was treated with hot water and sown, less than 1:10,000 of the plants were found to be infected.

A bacterial soft rot of certain cruciferous plants, H. A. HARDING and F. C. STEWART (*Science, n. ser., 16 (1902), No. 399, pp. 314, 315*).—For a number of years the writers have had under observation a soft rot of certain cruciferous plants, particularly of cabbage and cauliflower. During epidemics of black rot, due to *Pseudomonas campestris*, there is often much damage done by soft rot, and at first the disease was supposed to be a virulent form of black rot. Subsequently there were found several attacks of soft rot where there was little or no black rot, and this led to a further study of the cause of the disease.

From cauliflower beds which were severely attacked the writers isolated an organism which has been secured in pure cultures and inoculated into cabbage and cauliflower plants, producing the typical form of the disease. Cabbage and cauliflower plants inoculated between March 10 and June 17, with one exception, became rotten at the point of inoculation, while check plants showed no disease or discoloration. The extent of the rotting seems to be dependent upon the condition of the plant. On young, thrifty plants it progresses with great rapidity, while on old, woody, slow growing plants the signs of inoculation do not appear for several days, and in the majority of cases such plants are only checked in growth.

Cabbage and cauliflower leaves inoculated in the petioles usually become broken down at the point of inoculation within 48 hours. Young plants of kohlrabi and Brussels sprouts were successfully inoculated in the stem, ruta-bagas in the leaf petioles, and radish and flat turnip by inoculation in the fleshy roots. The organism was tested on a large number of different kinds of plants, and from present indications it is believed that it is one of a group of organisms closely related to *Bacillus carotovorus*, which has been described as occurring on carrot and other plants (E. S. R., 13, p. 362).

In addition to the cruciferous plants it was found that *Amorphophallus simlense*, an araceous plant, frequently cultivated by florists, was subject to destructive injury when its petioles were inoculated with the organism.

A preliminary note on a new organism producing rot in cauliflower and allied plants, F. C. HARRISON (*Science*, n. ser., 16 (1902), No. 395, p. 152).—During the summer of 1901 the author's attention was drawn to a disease of cauliflowers occurring in the vicinity of Guelph, Ontario. The plants, which were well grown, showed symptoms of rotting, the interior of the stem and often the flowering or edible part being changed into a dark-colored, soft mass. An examination of the material revealed the presence of enormous numbers of bacteria, and the casual organism was isolated and its relation to the rot established by inoculation experiments. The characteristics of the organism are briefly outlined, and in its action it is said to be similar to that described by Potter as attacking some other cruciferous plants (E. S. R., 13, p. 467). The name proposed for the organism is *Bacillus oleraceus*.

Club root of cabbage, L. MANGIN (*Rev. Hort.* [Paris], 74 (1902), No. 18, pp. 432-435, figs. 5).—A description is given of the club root of cabbage, turnips, cauliflower, and other cruciferous plants, which is due to attacks of *Plasmodiophora brassicae*. The organism is described in its various stages and the results of attempts to control the disease are given. The author recommends the rotation of crops wherever possible and the treatment of the soil with lime or phosphatic slag when rotation is not practicable. The debris of diseased plants should be collected and burned.

The banana disease, G. P. FORDEN (*Jour. Khediv. Agr. Soc. and School Agr.*, 4 (1902), No. 3, pp. 117-119).—An account is given of a disease of banana which is said to exist extensively in Fiji, and in connection with the recently described banana disease in Egypt it is of particular interest to that country. The outer leaves of the affected plants soon after they are set begin to turn brown and die, followed in a similar manner by the succeeding leaves. This continues for a considerable time, and instead of the plants attaining a height of 6 to 12 ft. they are greatly stunted and produce no fruit. An examination of these plants showed the presence of great numbers of aphids about the root stocks. In addition, the root stocks are infested with a fungus, the exact nature of which is not known. The tissues are discolored wherever the fungus is found. Great numbers of nematodes are found about the diseased plants, and the author believes that they have some part in the infection. Rotation of crops, deep cultivation with occasional subsoiling, and care in the selection of suckers for planting are recommended as means for the prevention of this disease.

Bitter rot of apples, T. J. BURRILL and J. C. BLAIR (*Illinois Sta. Bul.* 77, pp. 351-366, figs. 14).—In continuation of the statement previously given (E. S. R., 14, p. 367), the authors present additional data relating to the distribution of the bitter rot of apples. This disease is one of the most destructive to which the apple is subject, and it is said that in 4 counties in 1900 it occasioned a loss of a million and a half dollars' worth of fruit. The appearance of the disease upon the fruit is described and notes given on the way in which the fungus passes the winter. It has been usually considered that it was carried over winter solely in old diseased apples which dry up and remain for some time upon the trees. In certain investigations all the mummy fruit was removed, but the disease was still present. In July a cooperator of the station, R. A. Simpson, of Vincennes, Ind., called attention to the distribution of the disease in cone-shaped areas in the trees, the earliest infection being traceable to an old rough wound on the branches. A few days later another individual reported the same fact, and this led to a microscopic study of material which confirmed the connection between the cankered places on the limbs and the disease upon the fruit. Later inoculation experiments with spores from cankers produced typical bitter rot on the fruit in 4 days. It is therefore evident that the disease on

the apples could come from these canker spots on the branches, and it is probable that except in a few cases the first or early infection comes solely from these canker spots and not from the mummy fruit. The appearance of the bitter rot canker is described at some length and preventive measures are suggested. During the winter time the mummy fruits and cankers should be removed, or the fungus could probably be destroyed by spraying the trees with a solution of copper sulphate. The disease can be kept in check during the summer by repeated applications of Bordeaux mixture.

Pear blight in California. N. B. PIERCE (*Science*, n. ser., 16 (1902), No. 396, pp. 193, 194).—Pear-leaf blight, although doubtfully reported in California for many years, was observed in a typical form in southern California in 1899. The disease assumed its normal epidemic form and spread over several counties in a short time, occasioning great damage. In the spring of 1900 it had developed seriously in a number of widely separated regions, and is reported as occurring to a considerable extent in the leading pear growing districts of southern California, and of the San Joaquin and Sacramento valleys. It has hitherto been believed that the atmospheric conditions in the hot interior valleys of California would be detrimental to the destructive development of pear blight, but the facts presented are quite to the contrary.

In California there are said to be 2 distinct forms of the disease, a spring and summer form, likewise a winter epidemic, the latter form being by far the more destructive. The winter form of disease, which by inoculation experiments has been proved identical with the spring form, has some distinguishing characteristics. It seldom or never attacks the tree at points higher than a man's head, always affecting the trunk or base of the main limbs, and the infection takes place about the time the crop is gathered or shortly after, continuing active and destructive during the months of November, December, and January. It may also occur in orchards which have shown little or no signs of the spring form of the disease.

The infection usually occurs in the short spurs developed upon the base of the main limbs or on the trunk of the trees. These spurs not infrequently develop clusters of flowers late in the fall, and seldom occur more than 5 or 6 ft. from the ground. The winter temperature is sufficiently warm to permit the blight bacillus to grow, and as the affected parts can not be removed by pruning without detriment to the tree, the winter development has resulted in more serious injury and greater losses of trees than the spring form of the disease in the East. In the winter blight, as well as the spring form, the growing tips of purely vegetative shoots occasionally serve as points of infection. This has been shown possible by the visit of bees which are attracted to the buds for the deposit of glue or wax which occurs on the winter buds. The agency of bees in distributing the pear blight is shown by statements regarding the serious affection of a number of orchards near large colonies of bees.

Notes on canker and black rot. P. J. O'GARA (*Science*, n. ser., 16 (1902), No. 402, pp. 434, 435).—During the summer of 1901 several specimens of sumac (*Rhus glabra*), occurring on the campus of the University of Nebraska, were found affected with the canker caused by *Sphaeropsis rhoina*. During the summer of 1902 experiments were carried on to determine whether this fungus and the *S. malorum* occurring on the apple may not be the same. Pure cultures of each were made and their behavior was identical in every particular. Sound apples inoculated with spores, on the fourteenth day after inoculation, were blackened and densely dotted with the protruding pycnidia. Spores obtained from the inoculated apples were used to inoculate healthy branches of both the apple and sumac, and so far no differences can be observed in the growth of the different species. The experiment seems to establish that *S. rhoina* will cause the black rot on the fruit of the apple, and will also produce the typical canker on the branches and limbs just as readily as *S. malorum*. Although the evidence is not yet complete, it is believed that the 2 species are identical.

The gray rot of grapes. R. ROGER (*Jour. Agr. Prat.*, n. ser., 4 (1902), No. 39,

p. 411).—A brief account is given of the gray rot of grapes, due to *Botrytis cinerea*. The author recommends the removal of the leaves in such a way as to secure a better circulation of air about the plant and the consequent evaporation of moisture, and dusting the plants with a powder composed of 90 per cent gypsum and 10 per cent copper sulphate, or 80 per cent gypsum and 20 per cent neutral verdigris.

Diseases of the hardy catalpa, H. VON SCHRENK (*U. S. Dept. Agr., Bureau of Forestry Bul. 37, pp. 49-58, pls. 8, figs. 2*).—After describing the durability of the catalpa timber, the author considers some of the diseases to which this tree is subject. As a rule, the hardy catalpa is free from destructive diseases. The leaves are sometimes attacked by parasitic fungi which seldom occasion any material injury. The young twigs so far as known are seldom attacked by any fungus, and root diseases are likewise unknown. Under unfavorable conditions, however, there are 2 fungus diseases which destroy the wood of the trunk: One, a soft rot, caused by *Polyporus versicolor*, which destroys the heartwood of the catalpa very rapidly after it has once gained entrance; and a second disease, known as the brown rot, which is due to a new species of fungus to which the name *P. catalpæ* is given. The young shoots and leaves of the catalpa sometimes suffer from an apparent blight, in which the leaves and buds turn black, shrivel, and fall from the tree. This trouble seems to be widely distributed, and is due to the presence of the larvæ of one of the gall gnats.

Notes on some diseases of western conifers, H. VON SCHRENK (*Abs. in Science, n. ser., 16 (1902), No. 395, p. 138*).—The coniferous trees of the Pacific Coast and adjoining regions are said to be attacked by a number of fungus diseases, some of which destroy as much as 40 per cent of the standing timber. The more important diseases are caused by *Trametes pini*, *Polyporus schweinitzii*, *P. libocedris* n. sp., *Echinodontium tinctorum*, and *Polyporus officinalis*. The development of these fungi and the manner and extent to which they destroy wood are described.

The prevalence of Alternaria in Nebraska and Colorado during the drought of 1901, G. G. HEDGECOCK (*Abs. in Science, n. ser., 16 (1902), No. 395, pp. 136, 137*).—A report is given of the observations made by the author in various sections of Nebraska and Colorado during the period of severe drought in July and August of 1901. The conditions which existed seem to have retarded the development of such fungi as *Cercospora* and *Phyllosticta*, but favored the growth of *Alternaria*, the leaves of such plants as sugar beets, potatoes, pumpkins, cantaloupes, and plantains being severely blighted.

Sclerotinia fructigena, J. B. S. NORTON (*Abs. in Science, n. ser., 16 (1902), No. 395, p. 137*).—According to the author, previous studies of this destructive fruit disease have been confined to the conidial stage. He reports having found the apothecia abundantly on buried peach and plum fruits, which are described at some length. The cycle of development of the fungus is completed in a few days, and the connection between the apothecia and monilia form was demonstrated by laboratory cultures. On account of the formation of the fruiting organs on the buried fruits, the author states that diseased fruits should be burned or otherwise destroyed.

Arachniotus trachyspermus, a new species of the Gymnoascaceæ, C. L. SHEAR (*Abs. in Science, n. ser., 16 (1902), No. 395, p. 138*).—A description is given of the above fungus, which has been isolated in diseased cranberries grown in New Jersey. The fungus appears to be undescribed and, so far as known, not hitherto reported in the United States.

The finding of Puccinia phragmitis in Nebraska, J. M. BATES (*Abs. in Science, n. ser., 16 (1902), No. 395, p. 138*).—The author reports finding the aecidial stage of this fungus on the garden rhubarb in 1901, and the following year upon different species of *Rumex* occurring at a number of localities. This completes the life history of the fungus, which is believed to be new to this continent.

North American Ustilagineæ, G. P. CLINTON (*Jour. Mycol., 8 (1902), No. 63, pp.*

128-156).—Notes are given on studies made by the author during the past 2 years, which are preliminary to a monograph of the Ustilagineæ of North America which he hopes to issue in the near future.

Notes on some West American fungi, P. L. RICKER (*Jour. Mycol.*, 8 (1902), No. 63, pp. 125-128, fig. 1).—Notes and descriptions are given of a number of fungi which were collected in Wyoming and Idaho during 1901, together with a number of specimens found on grasses in the herbarium of this Department.

Plant pathological stations in Northern Europe, E. MARCHAL (*Bul. Agr. [Brussels]*, 18 (1902), No. 1, pp. 45-53).—A description is given of a number of plant pathological laboratories in Germany; Sweden, Denmark, and Holland which were visited by the author.

ENTOMOLOGY.

Proceedings of the fourteenth annual meeting of the Association of Economic Entomologists (U. S. Dept. Agr., *Division of Entomology Bul.* 37, n. ser., pp. 127, pl. 1, figs. 2).—At this meeting, held in Pittsburg, Pa., June 27 and 28, 1902, the following papers were read:

On the study of forest entomology in America, A. D. Hopkins (pp. 5-28).—This is the address of the retiring president, and contains notes on the present status of the study of forest insects in America, together with an account of some of the more serious outbreaks among the forest insects during recent years. A summarized statement is presented, showing some of the practical results of forest entomology.

Notes on the use of the lime-sulphur-and-salt and the resin washes in Ohio, A. F. Burgess (pp. 33-35).—Fruit trees sprayed with lime-salt-and-sulphur wash on December 31 were inspected on the following May 24, when it was found that about 98 per cent of the scales had been destroyed. This wash was also applied by several orchardists during March with satisfactory results. One case of apparent injury to peach twigs was observed on Catawba Island. Resin wash applied January 8 apparently destroyed all the scales, as judged by an examination made May 24. Similar experiments were made by fruit growers with this wash, with satisfactory results.

Experimental work in New York State against the San José scale, E. P. Felt (pp. 35, 36).—Excellent results in the destruction of the San José scale were obtained from the use of a 20 per cent mechanical mixture of crude petroleum; potash whale-oil soap, 2 lbs. to the gallon of water; tobacco whale-oil soap, 2 lbs. to the gallon of water; and linseed oil, either raw or boiled. No decided injuries were caused to any of the trees, except from the use of the linseed oil.

Report of experiments with lime-salt-and-sulphur wash against the San José scale in Maryland, A. L. Quaintance (pp. 37-40).—Applications of lime-salt-and-sulphur wash were made in 3 localities. Five-year-old plum trees were treated on March 4, and when examined later it was found that the treatment had not given satisfactory results. Two-year-old peach trees treated on March 27 and 28 were not injured by the application, but it appeared that only from 45 to 50 per cent of the scales were killed. Other peach trees treated on March 22 remained uninjured and the effectiveness of the application was much greater, about 98 or 99 per cent of the scales being killed.

Some practical experiments with various insecticides for the San José scale in Georgia, W. M. Scott (pp. 41-51).—Abstracted from another publication (see p. 589).

Soluble arsenic in arsenical insecticides, J. K. Haywood (pp. 51-54).—An examination of samples of Paris green showed that an excess of free arsenic may be due to the decomposition of Paris green in contact with water, to a fine pulverization of the Paris green, or to its being originally added to the material. In determining the soluble arsenious oxid in Paris green it is recommended that 1 part of the Paris green

be extracted with 1,000 parts of water for 10 days. All samples of London purple examined by the author showed the presence of more than 4 per cent free arsenic.

Résumé of the search for the native home of the San José scale in Japan and China, C. L. Marlatt (pp. 65-78).—Detailed notes are given on the itinerary of the author through Japan and China. Arguments are presented to show that Japan is not the native home of the San José scale. In China the scale was found on native crab-apples and haws and the author believes that the evidence for the origin of the scale in China is very good. It is suggested that the scale may have been carried from China to California on trees imported by James Lick.

Preliminary report on the importation and present status of the Asiatic ladybird, C. L. Marlatt (pp. 78-84).—Notes are given on the shipments of *Chilocorus similis* made by the author into this country, as well as upon previous importations into California by A. Koebele and into New Jersey by J. B. Smith. The beetles appear to be thriving well in this country, and it is believed that much may be expected from them in the future in the way of destroying the San José and other scales.

Predatory insects which affect the usefulness of scale-feeding Coccinellidæ, C. L. Marlatt (pp. 84-87).—Observations on ladybirds have shown that they are destroyed by the wheel bug, the native and introduced species of praying mantis, lace-winged flies, and by *Adalia bipunctata*. The wheel bug is considered to be a source of the greatest menace to the introduced ladybird larvæ. A parasite, *Syntomosphyrum cesurus*, has also been bred from the introduced ladybirds, but as this species belongs with a group of secondary parasites, it is suggested that the primary parasite may prove to be *Homalotylus obscurus*.

On the feeding habits of the adults of the periodical cicada, A. L. Quaintance (pp. 90-94).—Observations made by the author indicate clearly that both sexes of the periodical cicada puncture trees of various species and suck out the sap. These feeding habits were observed in a number of localities in Maryland, and the trees upon which the cicadas were observed include apple, pear, peach, plum, maple, oak, etc. The beak of the cicada was introduced into the wood for some distance while feeding, and when the insects were captured in the act of feeding and quickly opened it was found that the alimentary tract was considerably distended with sap.

Notes from Delaware, E. D. Sanderson (pp. 97-102).—The author presents a brief account of the various species of plant lice on apples, and means for combating them, as well as on the strawberry-root louse, codling moth, periodical cicada, strawberry weevil, and *Systema tennata*.

Notes for the year in New York, E. P. Felt (pp. 102, 103).—Brief statements concerning grape-root worm, grapevine leaf-hopper, apple-tree tent caterpillar, forest tent caterpillar, and fall webworm.

Observations on certain insects attacking pine trees, E. P. Felt (pp. 103-105).—Notes on *Tomicus calligraphus*, *T. pini*, *Monohammus confusor*, and *Dendroctonus terebrans*.

Egg-laying record of the plum curculio, A. L. Quaintance and R. I. Smith (pp. 105-107).—Observations were made on the laying habits of plum curculios, during which it was found that the largest number of eggs deposited by any single beetle was 436.

Notes from New Mexico and Arizona, T. D. A. Cockerell (pp. 107-109).—Brief notes on *Parlatoria blanchardi*, box-elder plant louse, *Clisiocampa constricta*, and a number of beetles.

A partial list of the Coccidæ of Ohio, F. M. Webster and A. F. Burgess (pp. 109-113).—The authors present a list of 71 species of Coccidæ, with a statement of the food plants upon which they were found.

Observations upon the mosquito, Conchyliastes musicus, H. A. Morgan (pp. 113-115).—The female of this species is said to attack mammals furiously, and to cause swellings on man as a result of its bites. The larvæ are active at the surface of the water for the first 24 hours, after which they may remain at the bottom for at least 47 minutes

without coming up for air. Notes are given on other points in the life history of this species.

Some notable insect occurrences in Ohio for first half of 1902, II. Osborn (pp. 115, 116).—Notes are given on clover-leaf weevil, chinch bugs, cankerworm, horn fly, fall webworm, and periodical cicada.

Report of the entomologist, J. B. SMITH (*New Jersey Stat. Rpt. 1901, pp. 463-587, figs. 36*).—This report contains, as usual, a general account of the insect depredations in New Jersey during the year. Notes are given on the prevalence and means of combating fall webworm, white-spotted tussock moth, catalpa sphinx, tomato hawk moth, swallow-tail butterflies, plant lice on currant, apple, strawberry, cherry, maple, plum, hickory, and pea, and various scale insects. The author had good success in the use of arsenate of lead in destroying fall webworm. Notes are given on the damage caused by the destructive pea louse and on experiments with machines specially devised for destroying this insect. Most of the experiments were made with potash whale-oil soap, 1 lb. to 6 gal. of water. This remedy proved effective and perfectly harmless to the plants. Among various kinds of scale insects mention is made of oyster-shell bark-louse, tulip soft scale, rose scale, and San José scale. The extension of the latter insect is said to be slower at present than in former years. It is not considered a menace to shade and forest-trees. Crude petroleum is considered the best remedy, while lime-sulphur-and-salt wash was used with excellent success. Notes are also given on shade tree insects (including elm-leaf beetle, wood leopard moth, bagworm, and an undetermined maple-leaf stalk borer); orchard insects (including rosebugs, silky June beetles, plum curculio, sinuate pear borer, pear midge); and also on Hessian fly, angoumois grain moth, rhubarb beetles, asparagus beetles, tortoise beetles, potato beetles, cranberry insects, mosquitoes, and *Ligyrus relictus* said to be injurious in a larval stage upon the roots of pyrethrum. Experiments were made with a number of insecticides, including arsenate of lead, whale-oil soap, tobacco extract, Yankee Yellow, Pyrox, Hammond's Thrip Juice, Kretol, and petroleum. Whale-oil soap did not prove a successful remedy as a winter treatment of San José scale. The results obtained with this insecticide in summer were very satisfactory. The author gives a detailed report of some operations with crude petroleum as an insecticide. It is believed that this material is the best insecticide for use against San José scale. The preferred period for application is just previous to the beginning of growth in the spring.

Notes are given on 2 introduced beneficial insects, *Tenodera sinensis* and *Mantis religiosa*. Eggs of these insects were introduced into New Jersey, but it is not known at present whether the insects have been successfully established in the State. The author refers briefly to the miscellaneous work of his department and to the insects mentioned in the crop bulletins in New Jersey. An investigation was made of injury to cranberries by the cranberry katydid, *Scudderia texensis*. A number of experiments were made in testing the value of fungus diseases in destroying this insect. In experiments made on cranberry bogs it was found that the eggs of this insect were often laid in the leaves of *Panicum dichotomum*. It is not certain whether the eggs can survive the winter underneath the cranberry bogs in such situations. Notes are given on the habits and life history of the insect. It is concluded that no reliance can be placed on fungus diseases of this insect, or on insecticides, or the cooperation of turkeys and other fowls. It is recommended that the underbrush and rubbish on the ground surrounding the bogs be burned annually. This can perhaps be best accomplished by the use of the cyclone burner, such as was employed by the Gypsy Moth Commission.

The author presents a detailed account of the mosquitoes in New Jersey, including a discussion of their prevalence and means of distribution, the species concerned, and the results which have thus far been accomplished in the investigation of means for exterminating them. Circular letters were sent to various parts of the State for the

purpose of determining the distribution of mosquitoes. The author states that while *Anopheles* may be one means of transmitting malaria from one person to another, another factor thus far unknown is required in the transmission of the disease. Detailed notes are given on the various species of mosquitoes found in New Jersey, and upon their breeding habits and means of spreading from one part of the State to another.

Report of the botanist and entomologist, G. W. HERRICK (*Mississippi Sta. Rpt. 1902*, pp. 31-33).—Brief notes on mosquitoes, pecan insects, chicken lice, Colorado potato beetle, peach-tree borer, San José scale, and fumigation with hydrocyanic-acid gas and Nicotinic acid.

Winds and storms as agents in the diffusion of insects, F. M. WEBSTER (*Amer. Nat.*, 36 (1902), No. 430, pp. 794-801).—Brief popular notes on the influence of winds and thunderstorms upon the habits and diffusion of insects.

Flowers and insects in New Mexico, T. D. A. COCKERELL (*Amer. Nat.*, 36 (1902), No. 430, pp. 809-817).—Notes on the insect visitors of a number of flowers in different parts of New Mexico.

Injurious insects, E. FLEUTIAUX (*Agr. Prat. Pays Chauds*, 2 (1902), No. 8, pp. 229-234).—Brief notes are given on the habits and life history of *Brachytripes membranaceus*, which causes serious damage to coffee trees in Madagascar; *Centrinus sipolisi*, injurious to the custard apple; *Coreyra translucella*, which attacks the seeds of sesame. A brief list is given of insects collected along the Mouni River.

Injurious insects observed in Ireland during the year 1901, G. H. CARPENTER (*Econ. Proc. Roy. Dublin Soc.*, 1 (1902), III, No. 5, pp. 132-160, pl. 1, figs. 27).—Detailed notes are given on the life history and injuries caused by the sheep-fly (*Lucilia sericata*). Observations show that this fly deposits its eggs in clusters of about 50 in the wool of the sheep, and that heavy woolled fat sheep, especially such as are in an uncleanly condition, are most liable to attack. The insect may irritate the skin so extensively as to cause great loss of flesh, or death in some instances. Ordinary sheep dips are not effective in destroying this insect, but constant use of sulphur or lime dust and frequent examination of the wool will serve to prevent serious injury.

Notes are given on *Phyllotreta nemorum* injuring turnips, cabbage-root maggots, diamond-back moth, frit fly, bean weevil, pea weevil, ground beetles, pear thrips, and a number of other injurious insects. For combating injurious ground beetles poisoned bait in tin dishes is recommended.

Insects injurious to fruit and vegetables, H. T. FERNALD (*Trans. Massachusetts Hort. Soc. 1901*, I, pp. 141-143).—A general account of the extent of injuries due to insects with special reference to the ravages of the San José scale.

Inspection of fruits and plants; orchard notes for August, G. QUINN (*Jour. Agr. and Ind. South Australia*, 6 (1902), No. 1, pp. 25-29).—A brief description is given of the inspection system which is in force in South Australia, and notes are presented on the time of appearance of several important injurious insects, together with recommendations of treatment.

Insects injurious to fruit trees, H. FAES (*Chron. Agr. Canton Vaud*, 15 (1902), No. 15, pp. 449-459, figs. 6).—Notes are given on the habits, life history, and means of combating woolly aphis, apple aphis, plum aphis, peach aphis, various species of scale insects, including oyster-shell bark-louse, peach scale, San José scale, and *Grapholitha funebrana*.

Suggestions for controlling the importation of insect pests, H. MAXWELL-LEFROY (*West Indian Bul.*, 3 (1902), No. 2, pp. 140-150).—The author classifies the various insect pests known in the West Indies into groups arranged according to the degree of damage caused by the insects. Scale insects, of which 120 species are known in the West Indies, are arranged in 3 classes, considered as very destructive, moderately destructive, rare and harmless, respectively. Among these species the

great majority of very destructive species have been introduced from various foreign sources. Notes are given on the insects which are likely to be introduced and on the means of distribution of injurious insects among the West Indian Islands. The author recommends the prohibition of special importations, the destruction of infested plants upon arrival, and the treatment of all imported plants by fumigation or some other method.

Certain leaf-eating caterpillars of the sugar cane, W. VAN DEVENTER (*Meded. Proefstat. Suikerriet West Java, 1902, No. 56, pp. 12, pl. 1*).—Descriptive notes are given on *Pamphila augias*, *Hesperia philino*, *H. mathias*, and *H. conjuncta*.

Cane borer (*Diatræa saccharalis*), W. C. STUBBS and H. A. MORGAN (*Louisiana Insect. Bul. 70, 2. ser., pp. 885-927, figs. 11*).—Notes are given on the history of this insect in the Southern States and its general distribution. Circular letters were sent to cane growers in the various parts of the State, the replies to which indicate that the borer is at present distributed chiefly in the parishes of Assumption, Ascension, and Iberville on the east and west banks of the Mississippi. Various remedial measures are practised by the cane growers, but the most effective one is burning all of the trash. The details of the life history of this insect were worked out in both cane and corn, the 2 most important food plants of the species. It was found that the larvæ which emerge from eggs in November do not pupate until the following March or April, while in July the larval period is usually from 25 to 28 days. This prolongation of the larval period is of considerable importance in combating the insect. The pupal condition is always spent in the cane stalk. About 87 per cent of the moths appear before April 15. In the corn plant the borers destroy the terminal leaves. It is believed by the authors that the corn plant is largely responsible for the increase of the sugar-cane borer in the State.

In combating this insect it is important to remember that the moths can not escape from buried cane; the borer, therefore, can not increase its distribution from fall-planted cane, unless the tops are left upon the ground undestroyed. The windrowing of canes is condemned as a practice which allows the extensive distribution of the insect. The cane tops or other material in which the borer may be found should either be buried or burned. During the author's experiments 100 stalks of cane were buried at different depths, varying from 6 in. to $\frac{1}{2}$ in. The results indicate that in some soils many of the borers died and that the moths were unable to escape, even when the cane was buried to a depth of $\frac{1}{2}$ in. It is recommended that neither corn nor a second crop of sugar cane be planted on windrowed ground until the borers have been eradicated. The cutting out of infested stalks of corn and cane may be accomplished without any great expense. In one instance 2,000 acres were thus treated at an expense of \$170. The chief natural enemies of the sugar-cane borer are the larvæ of *Chauliognathus marginatus* and *Drasterius elegans*; ants and an unidentified white fungus have also been observed attacking this insect.

The turnip sawfly and injuries caused by this insect in the vicinity of Paris in 1901, P. MARCHAL (*Ann. Min. Agr. [France], 21 (1902), No. 2, pp. 295-304, figs. 2*).—Descriptive biological and economic notes are given on *Athalia spinarum*. The insect is injurious to all cultivated members of the mustard family and to various wild species of this family. In the adult stage it lives not longer than 15 days. The injury is caused by the larvæ, which skeletonize the leaves. There are 2 generations per year, the first generation of adults appearing in May and the second in August. This species of sawfly is found in England, Continental Europe, and as far east as Japan. It has appeared in large numbers, causing unusual destruction at various times. The invasion of 1901 was attended with great destruction to cruciferous plants. In some localities crows are useful in destroying this insect. A number of other birds, particularly ducks, feed upon the insect. It is also attacked by various parasites and by a bacterial disease. The remedies which are recommended for

controlling it include spraying with kerosene emulsion, rape-seed oil, powdered lime, and the use of trenches and brushes, as well as collection of the adult insects and rotation of crops.

The fruit fly, J. LANDSAY (*Queensland Agr. Jour.*, 11 (1902), No. 1, pp. 21-23).—In combating the attacks of the fruit fly upon oranges the author had the best success in collecting a few of the oranges which first ripened and placing them on the ground near the tree, smearing them with some preparation like "tanglefoot" used for catching flies. The oranges thus treated are placed in position in the evening, and the observations made by the author indicate that flies in attempting to oviposit in the oranges are captured in large numbers.

Winter treatment of the San José scale in the light of recent experiments, W. M. SCOTT and W. F. FISKE (*Georgia State Bd. Ent. Bul.* 4, pp. 32, pls. 2).—During the past winter over 500,000 trees in Georgia were sprayed with petroleum oils in some form. A number of other insecticides, including whale-oil soap, lime-salt-and-sulphur wash, crude caustic potash, etc., were used and notes are given on the results of the experiments with these insecticides. The experiments were confined to peach trees and were conducted in 2 orchards containing 17,000 trees 2 years of age and 200,000 trees 4 years of age respectively. In one orchard only about 10 per cent of the trees were free from the scale, while in the other about 25 per cent were badly infested. Insecticide work was begun on November 30 and was continued at intervals during December, January, February, and up to March 7. Several kinds of oil were used, including Pennsylvania crude oil, refined kerosene, Ohio crude oil, and California distillate. From the extensive experiments carried on by the authors it appears to be impossible to decide definitely as to the comparative merits of kerosene and crude oil. They are considered the 2 best remedies, good results having been obtained from 2 applications of either one, at a strength not lower than 15 per cent. The results appear to be slightly in favor of the effectiveness of crude oil. Two applications proved much more effective than one. In many cases 1 application was quite inadequate while 2 applications, even of weaker solutions, were very effective. A comparison was made between fall and spring spraying. It was found that a greater proportion of the scale was killed on trees sprayed in the spring than on those sprayed in the fall or winter. There are, however, many strong and obvious advantages in favor of treatment in the fall. A careful comparative test was made of a mechanical mixture of oil and soap emulsion. As a result of this test it is stated that, all things considered, the oil may be applied as cheaply and with less trouble in the form of emulsion than in the form of mechanical mixtures.

Tests were made of different strengths of oil, including 10, 15, 20, and 25 per cent solutions. It was found that a 25 per cent solution is required for young, healthy, infested orchards, while 2 applications of a 15 per cent solution proved effective in older orchards.

Observations made for the purpose of determining the influence of the weather on spraying gave only negative results. No apparent influence of the weather was determined. The Ohio crude oil was used on several plats of trees with good success. California distillate, at strengths of 10, 15, and 20 per cent, was sprayed on 200 trees, with no better results than those obtained from ordinary oils.

Whale-oil soap was used in solutions of 1½ and 2 lbs. to the gallon of water. The weaker solution was found to be unsatisfactory, even in 2 applications, while a single spraying with a solution of 2 lbs. to the gallon was very effective. None of the applications of whale-oil soap made during the fall and winter were successful. The experiments indicate that whale-oil soap should be applied in the spring as late as possible before the blossoms open. A single application of potash soap, at the rate of 2 lbs. to the gallon of water, under good conditions, gave as good results as single applications of a 25 per cent strength of kerosene or crude oil, either in mechanical

mixture or in an emulsion. The general effect of whale-oil soap on trees was apparently beneficial, with 1 exception. The lime-salt-and-sulphur wash was carefully tested. The effect of this insecticide on the scales was not at once apparent, but the ultimate results were as satisfactory as those obtained from 2 applications of kerosene emulsion. This insecticide is considered equal to any treatment, except 2 applications of kerosene or crude oil. The cost of the material for lime-salt-and-sulphur wash is much less than that of oil; the cost and trouble of preparation, however, is more than that of the oil emulsion. One test was made of resin wash, with poor results. It proved also to be a difficult matter to prepare this insecticide properly. Crude caustic potash was tested in solutions containing 5, 10, and 15 lbs. to 50 gal. of water. The weak solution was ineffective, but the 2 stronger ones gave good results. The trees were not injured by any of the solutions. Crude carbolic acid was tested in various forms, with unsatisfactory results in all cases.

In addition to the experiments already mentioned, 53 3-year-old peach trees and 1,000 plum trees were treated. Various strengths of kerosene and crude oil were used throughout the season in spraying these trees. The results were highly satisfactory. The trees bloomed and put out leaves in a normal manner and bore an excellent crop of fruit. The scale was perhaps as nearly eradicated as possible. Notes are given on the methods of preparing oil emulsion, lime-salt-and-sulphur wash, whale-oil soap, and crude caustic potash.

The codling moth, G. QUINN (*Jour. Agr. and Ind. South Australia*, 6 (1902), No. 2, pp. 110-114).—A circular letter was sent to a number of prominent apple growers in Tasmania for the purpose of securing statements concerning the effectiveness of measures which had been adopted in controlling the codling moth. The majority of the fruit growers express the opinion that governmental inspection is necessary for effective work in controlling this insect. Attention is called, however, to the necessity of conscientious work on the part of the inspectors.

Spraying tests for the codling moth, G. QUINN (*Jour. Agr. and Ind. South Australia*, 6 (1902), No. 1, pp. 19-21).—A series of experiments were undertaken for the purpose of determining a suitable method for combating this insect. The trees were sprayed at intervals of 2 weeks, beginning immediately after the fall of the petals. The insecticides used were Paris green, 1 oz. to 10 gal. limewater (made by slaking 1 lb. of fresh lime); and arsenite of soda (made by boiling 1 lb. of white arsenic and 2 lbs. of soda crystals in 1 gal. of water, which was then diluted at the rate of 1 pt. in 40 gal. of limewater). Different blocks of trees were sprayed 4, 5, 6, and 7 times respectively with Paris green. These blocks showed 89, 93, 94, and 83 per cent of apples respectively free from codling moth. In the 4 rows which were not sprayed 57 per cent of the apples were free from codling moth, while on 4 rows which were sprayed 5 times with arsenite of soda 94 per cent were free from attack.

The peach worm, W. T. CLARKE (*California Sta. Bul.* 144, pp. 44, figs. 20).—The peach worm (*Anarsia lineatella*) is said to be the most serious insect pest of the peach of California, where the damage in some seasons amounts to 30 per cent of the entire crop. The insect is known under the names bud worm and fruit worm, according to the part of the peach tree which it injures at different seasons of the year. The author's experiments were made on 200 acres of peach trees of different varieties containing about 12,000 trees, and these experiments were duplicated on a smaller scale in many other localities. During the winter the insect hibernates in a burrow within the bark in the crotches of the tree where the new wood joins that of the previous year. The burrow is always on the upper side of the crotch. The insect is not attacked by parasites during the hibernation period to any appreciable extent. The distribution of these winter burrows of the species was found to correspond with the extent to which old infested peaches had been thrown around the trees as a fertilizer. This custom is condemned as responsible for spreading the insect. It was found that pruning could not be depended upon for controlling this insect.

Spraying experiments were instituted on January 9 and were continued until the middle of the month. Kerosene emulsion of 2 strengths was used, but this insecticide appeared to have no beneficial effect. It was found by examining the larvæ in their winter burrows that the silk casing by which they were surrounded protected them against not only kerosene emulsion but distillate oil, lime-salt-and-sulphur spray, and other materials. No differences were noted between the sprayed and the unsprayed trees if spraying was performed during the winter. It was found necessary to wait until the larvæ became active in the spring. During the spring spraying experiments lime-salt-and-sulphur mixture, oils, emulsions, and I X L were used. The latter insecticide was used on 8,300 peach trees with very unsatisfactory results. The best results were obtained from the use of the lime-salt-and-sulphur mixture. The use of oils and emulsions, including the so-called Hercules emulsion made from distillate oil, caused more or less destruction of the blossoms and injury to the trees.

The larvæ remained in their burrows until early in March when they escaped and attacked the young growth, boring into the pith. This attack is more noticeable on young than on old trees. The larvæ remain in the buds and new twigs until the latter part of April. The larvæ seek the curled pieces of bark on the trunks and branches of the tree for pupation, the large proportion of the larvæ pupating low down on the trunk. Banding experiments showed that the larvæ did not prefer the bands to the curled pieces of bark. The moths appear in from 10 to 12 days and begin to lay their eggs about May 9 about the bases of the leaves. The larvæ from these eggs bore into the pith and remain as twig borers for about 20 days, when they leave the twigs and enter the fruit. The next generation exhibits a similar life history, while the larvæ from the third generation enter the bark in the crotches of the tree and pass the winter in this condition. For combating this insect the author recommends spraying with the lime-salt-and-sulphur compound just before the blossoms open, or even after the blossoms have opened.

Insects of the wattle trees, W. W. FROGGATT (*Agr. Gaz. New South Wales*, 13 (1902), No. 7, pp. 701-720, pls. 3).—Certain species of the genus *Acacia* known as wattle trees in Australia are among the most important trees of that country. These trees are frequently damaged to a great extent by various species of insects, and in the present article the author has brought together descriptions of a large number of species of insects which injure these trees. The insects which are described include various species of beetles, moths, flies, scale insects, and other Homoptera. A number of the injurious species considered are well illustrated on plates.

The effect of *Aphrophora salicis* on willows, A. JACOBI (*Arb. K. Gesundheitssamte, Biol. Abt.*, 2 (1902), No. 4, pp. 513, 514).—The author's observations were confined largely to the injurious effects of this insect upon *Salix alba*. It was found that where the insect was present in large numbers the leaves were greatly injured by the numerous punctures and the whole plant became stunted.

Felted beech coccus (*Jour. Bd. Agr. [London]*, 9 (1902), No. 2, pp. 218, 219).—*Cryptococcus fagi* attacks chiefly the trunks of beech trees. It is recommended that infested trees be twice sprayed with strong kerosene emulsion, with an interval of 2 days between the applications.

Hydrocyanic-acid gas in greenhouses, H. C. PRICE (*Amer. Florist*, 19 (1902), No. 750, pp. 405, 406).—A number of tests were made with this substance in fumigating greenhouses for the destruction of injurious insects. It was found that plants were less injured by exposure for a short time to a large amount of gas than by a long exposure to a small amount of gas. The method of fumigating with dilute gas is therefore not recommended.

Fumigation under box covers, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope*, 21 (1902), No. 1, pp. 54-64, figs. 4).—The author briefly describes, in connection with illustrations, the more important box fumigators which have been constructed in different countries for use in combating the San José scale.

Ortel's traps for catching locusts, R. DE SAINT-FOIX (*Bul. Agr. Algérie et Tunisie*, 8 (1902), No. 14, pp. 343, 344).—It was found that by sinking troughs into the soil and partly filling them with water covered with a film of oil the locusts could be induced to jump into the trough, provided a number were caught by other methods and thrown into the film of oil.

The fundamentals of spraying, A. V. STEUBENRAUCH (*Pennsylvania State Dept. Agr. Bul.* 93, pp. 35, pls. 10, figs. 4).—Reprinted with slight changes of phraseology from Illinois Station Bulletin 68 (E. S. R., 13, p. 876).

Alphabetical index to North American Orthoptera described in the eighteenth and nineteenth centuries, S. H. SCUDDER (*Boston Soc. Nat. Hist., Occasional Papers*, VI, 1901, pp. 436).—In this paper the author has compiled a list of all known definite references to the Orthoptera of North America and the West Indies, from the time of Linnaeus to the close of the last century. The paper includes an alphabetical index of all the species arranged according to genera, and bibliographical references under each genus, a bibliographical list of all literature cited, and an index to the specific names mentioned in the paper.

The salt-marsh mosquito (*Culex sollicitans*), J. B. SMITH (*Science*, n. ser., 15 (1902), No. 401, pp. 391-394).—The experiments and observations of the author on this insect show that the adult deposits its eggs singly in the mud of salt marshes above ordinary high tide where the sod is not too wet. The eggs may also be laid in other situations. They remain in the mud for an indefinite time until unusually high tide or heavy rain covers them with water; they then hatch within a few minutes and the larvæ feed on the decomposing mud. The larvæ seem to thrive well in both salt and fresh water.

Clothes moths (*Jour. Bd. Agr. [London]*, 9 (1902), No. 2, pp. 221, 223).—Biological and economic notes are presented on *Tinea pellionella*, *T. biselliella*, and *T. tapetzella*. The attacks of these insects may be prevented in large part by frequent removal and beating of clothes. Exposure to sunlight, the use of benzine, and cold storage at a temperature of 40° F. are recommended.

Furniture beetles (*Jour. Bd. Agr. [London]*, 9 (1902), No. 2, pp. 219-221).—Notes are given on the habits and life history of *Anobium domesticum* and *Xestobium tessellatum*. As a remedy for these insects it is recommended that cracks of furniture be painted with a solution of corrosive sublimate, or that infested material be treated with benzine or carbolic acid. Fumigation with hydrocyanic acid, where practicable, is exceedingly effective.

Economy in bee keeping, E. FORREST (*Jour. Jamaica Agr. Soc.*, 6 (1902), No. 7, pp. 259-261).—Attention is called to the necessity of keeping the hives and all equipment around the apiary in a clean condition in order to avoid diseases among the bees and to secure a better and more marketable grade of honey.

Apiculture and serotherapy, P. ROBINET (*Rev. Internat. Apicult.*, 24 (1902), Nos. 6, pp. 133-137; 7, pp. 144-148).—The anatomical details of the stinging apparatus of bees are carefully described and brief recommendations are made concerning means which may be adopted for avoiding bee stings. Natural immunity to the bad effects of bee stings is acquired in many individuals after being stung from 1 to 30 times. The blood serum appears to acquire specific antivenin, which neutralizes the effect of the sting. It is suggested that experiments along this line may perhaps demonstrate the possibility of artificial immunization by means of serum vaccination.

Foul brood and its prevention in Ireland (*Jour. Bd. Agr. [London]*, 9 (1902), No. 2, pp. 223, 224).—Notes are given on the distribution and prevalence of this disease in Ireland. It is stated that for the purpose of facilitating the adoption of reliable methods for treating this disease hives are being provided with a hole which may be closed with a shutter; a cloth or sponge saturated with a 10 per cent solution of formalin may be inserted in the hole for fumigation purposes.

Bombyx faidherbei, DUMAS (*Agr. Prat. Pays Chauds*, 2 (1902), No. 8, pp. 235, 236).—The larva of this silkworm lives on the lower surface of the leaves of *Zizyphus orthacantha*, and is of about the size of the larva of the common silkworm. The total duration of the larval period is about 42 days. It is stated that the moth closely resembles the common silkworm moth. The female lays 50 to 100 eggs and the period of incubation is from 7 to 8 days.

FOODS—NUTRITION.

Scope and results of the nutrition investigations of the Office of Experiment Stations, A. C. TRUE (*U. S. Dept. Agr., Office of Experiment Stations Rpt. 1901, pp. 437-482*).—A brief historical account of the growth of nutrition investigations in the United States, together with detailed statements of those carried on under the auspices of the Office of Experiment Stations and suggestions regarding future work.

The form in which starch occurs in fresh and stale bread, L. LINDET (*Bul. Soc. Chim. Paris, 3. ser., 27 (1902), No. 12, pp. 634-639*).—Using the methods which he has elaborated, the author studied the starch and its derivatives in the crust and crumb of bread and in fresh and stale bread. The results of his analyses of the crust and crumb of bread follow, the coefficients of absorption representing the ratio of the space occupied by a gram of wet starch to that occupied by a gram of dry starch:

Comparison of the crust and crumb of bread.

	Water.	In dry matter.		For 100 parts of total starch—			Coefficient of absorption.
		Reducing sugar.	Saccharose.	Dextrin.	Starch soluble. ^a	Starch insoluble. ^a	
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	
Crumb interior.....	44.8	1.2	0.6	6.7	10.7	82.6	4.4
Crumb surface.....	44.1	1.3	.7	9.6	10.6	79.8	4.6
Lower crust.....	19.3	1.4	.9	16.9	2.1	81.0	4.7
Upper crust.....	15.7	1.3	.9	11.8	1.5	81.7	4.1

^a In dilute hydrochloric acid.

Similar determinations were made with the crust and crumb of freshly baked and stale bread, which show, according to the author, that as bread grows stale the water content of the crust increases, while the dextrin content, the proportion of starch insoluble in dilute hydrochloric acid, and the coefficient of absorption remain practically unchanged. On the other hand, in the case of the crumb, the water content, the percentage of dextrin, and the coefficient of absorption diminish, while the proportion of starch insoluble in dilute hydrochloric acid increases. The results are discussed in relation to the food value of bread.

The effect of decortication and grinding upon assimilation, and experiments on the effect of adding wheat flour to rye bread, K. B. LEHMANN (*Arch. Hyg., 45 (1902), No. 2, pp. 177-211*).—The author studied especially the digestibility of Avedyk and Steinmetz rye breads as compared with ordinary rye bread, and also the digestibility of bread made from a mixture of rye and wheat. The conclusion is drawn that bread made from rye, ground according to the Steinmetz method and containing not less than 15 per cent of bran, was about equal in nutritive value to ordinary rye bread.

Rice for bread making, H. NEUVILLE (*Jour. Agr. Trop., 2 (1902), No. 16, pp. 292-294*).—A discussion of the use of rice mixed with wheat flour for bread making, with citations from early and recent work on the subject.

Some uses and abuses of common foods, EMMA J. DAVENPORT (*Illinois Assoc.*

Dom. Sci. Rpt. 1902, pp. 70-78).—The author discusses especially the erroneous views often advanced regarding the food value of potatoes, white wheat flour bread, and pork.

Canned salmon, T. MACFARLANE (*Lab. Inland Rev. Dept. Ottawa, Canada, 1901, Bul. 76, pp. 17*).—No added preservative was found in 100 samples of canned salmon examined. Ninety-five per cent of the samples were considered satisfactory as to quality.

Composition of poi, E. C. SHOREY (*Pacific Commercial Advertiser, Honolulu, 1902, Sept. 18, p. 11*).—Partial analyses are reported of 8 samples of poi obtained in Honolulu.

Uses of marine algæ in Japan, K. YENDO (*Postelsia, the Yearbook of the Minnesota Seaside Station, 1901. St. Paul, 1902, pp. 3-18, pls. 6*).—A number of marine algæ are described which are used in Japan for food and for other domestic purposes.

The use of bamboo seed as food, M. WALLINGER (*Indian Forester; abs. in Rev. Sci. [Paris], 4. ser., 18 (1902), No. 3, p. 94*).—Facts are given regarding the use of bamboo seed for food in India.

Cocoa and chocolate, A. MCGILL (*Lab. Inland Rev. Dept. Ottawa, Canada, 1900, Bul. 72, pp. 12*).—Analyses of a number of samples of cocoa and chocolate are reported.

Cloves, T. MACFARLANE (*Lab. Inland Rev. Dept. Ottawa, Canada, 1900, Bul. 73, pp. 14*).—This bulletin contains a report of the examination of a number of samples of cloves, whole and ground.

Subject list of works on domestic economy, foods, and beverages (*Patent Office [London] Libr. Ser. No. 9, Bibl. Ser. No. 6, 1902, pp. 136*).—In addition to works on domestic economy, food, and beverages, this volume, as is stated in the subtitle, includes articles on the culture of cacao, coffee, barley, hops, sugar, tea, and the grape.

Technical education of bakers and confectioners, C. T. MILLIS (*Jour. Dept. Agr. and Tech. Instr. Ireland, 2 (1902), No. 4, pp. 601-608, pl. 1, figs. 2*).—A description of the London, England, National School of Bakery and Confectionery, and the course of instruction provided.

Concerning tin from a hygienic standpoint, especially that found in preserved foods, K. B. LEHMANN (*Arch. Hyg., 45 (1902), No. 1, pp. 88-115*).—A review of the literature on the subject and experiments, which are reported, led to the conclusion that tin may cause acute digestive disturbances which are usually not serious. Other deductions have to do with special phases of the subject.

Concerning the occurrence and identification of fruit sugar in the fluids of the human body, C. NEUBERG and H. STRAUSS (*Ztschr. Physiol. Chem., 36 (1902), No. 2-3, pp. 227-238*).—The authors' investigations led to the conclusion that occasionally, though not always, levulose is found in the blood serum and other fluids of the human body and occurs whether levulose has been consumed or not.

The digestibility of fats and oils, with special reference to emulsions, J. W. WELLS (*British Med. Jour., 1902, No. 2181, pp. 1222-1224*).—A very brief account of experiments on the digestibility of cod-liver oil, cod-liver-oil emulsion, and petroleum emulsion. The metabolism of nitrogen was also studied.

Concerning the effect of muscular work upon metabolism, I. KAUP (*Ztschr. Biol., 43 (1902), No 2, pp. 221-255*).—Experiments were made, of which the author was the subject, on the effect of muscular work on the metabolism and excretion of nitrogen, sulphur, and phosphorus. The muscular work consisted in mountain climbing. The author's conclusion was that considerable muscular work can be performed without increasing the cleavage of protein provided the diet contains an abundance of nitrogen-free nutrients. In discussing his results the author takes account of the lag in the excretion of the constituents studied. The digestibility of the ration was not affected by the muscular work performed.

Albumin in relation to hygiene and the feeding problem, FINKLER and H. LICHTENFELT (*Centbl. Allg. Gesundheitspf.*, 21 (1902), *Sup.*, pp. VI+186).—The authors discuss especially the nutritive value of meat extracts, plasmon, and other similar nitrogenous food products. In many cases the analyses of such goods are reported as well as digestion and metabolism experiments.

Experiments on the amount of food required daily by man with especial reference to protein, R. O. NEUMANN (*Arch. Hyg.*, 45 (1902), No. 1, pp. 1-87, *dyms. 3*).—The author discusses dietary standards and summarizes results, quoting extensively from the literature of the subject. He also reports dietary studies and metabolism experiments, of which he was himself the subject, covering a total of 746 experimental days. On an average the daily diet furnished 74.2 gm. protein, 117 gm. fat, and 213 gm. carbohydrates, the energy value being 2,367 calories. This was sufficient for maintaining the body weight, which was on an average 70 kg. The conclusion is drawn that it is possible to maintain nitrogen equilibrium on a much smaller quantity of protein than Voit's standard calls for without, at the same time, increasing the amount of carbohydrates. On the contrary, he believes the amount of carbohydrates (500 gm.) may be diminished. The author discusses his results at length and among other points considers the energy value of alcohol. The article contains a bibliography.

ANIMAL PRODUCTION.

Analyses of commercial feeding stuffs, J. L. HILLS, C. H. JONES, and B. O. WHITE (*Vermont Sta. Bul.* 97, pp. 11-24).—In accordance with the State feeding stuff law, analyses were made of 218 samples of cotton-seed meal, cotton-seed feed, old and new process linseed meal, gluten meals and feeds, commercial feeds and cereal breakfast food by-products, calf meal, and animal meal. None of the cotton-seed meals, feeds, or wheat products was found to be adulterated.

"The better grades of oat feeds, corn and oat feeds, etc., were found, as usual, to meet the claims made for them by the manufacturers. The poorer grades—likewise as usual—were of lower grade than even their small promises indicated.

"Ninety per cent or thereabouts of the provenders (other than the output of the oatmeal mills) seem to be above reproach. Ten per cent were more or less open to question, while a few were almost surely laden with extraneous hulls."

Fodders and feeds, L. A. VOORHEES and J. P. STREET (*New Jersey Stat. Rpt.* 1901, pp. 78-136).—*Concentrated feeding stuffs* (pp. 78-128).—Abstracted from another publication (F. S. R., 12, p. 675).

Average analyses of fodders and feeds (pp. 129-134).—A compilation of analyses made at the station of fodders and feeding stuffs.

Market prices of commercial feeds (pp. 135, 136).—The authors give in tabular form figures showing the average cost of a number of commercial feeds in New Jersey since 1895, the records on which the figures are based in each case covering the 6 months preceding January 1.

By-products of the starch industry in the United States (*Jour. Soc. Arts*, 50 (1902), No. 2592, pp. 737, 738).—A brief descriptive and statistical article on starch by-products used as feeding stuffs.

Zein as a nutrient, I. W. SZUMOWSKI (*Ztschr. Physiol. Chem.*, 36 (1902), No. 2-3, pp. 198-218, *pl. 1*).—The chemical characteristics and feeding value of zein, the principal proteid of maize, were studied. According to the author, dilute caustic alkali (1 per cent solution) induces a modification of zein which is soluble in water. When maize was fed to geese and doves zein did not accumulate in the organs of the body. Zein injected into the circulation acted as a poison and was stored up in the liver.

Experiments on the composition and digestibility of dried potatoes, O. KELLNER, J. VOLHARD, and F. HONCAMP (*Deut. Landw. Presse*, 29 (1902), No. 85,

p. 691).—A sample of dried potatoes was prepared and analyzed. The dried and ground material, when mixed with water, is said to resemble cooked potatoes. The digestibility of this material was studied with sheep, the following coefficients of digestibility being obtained: Dry matter 80.1, organic matter 81.5, protein 19.5, and nitrogen-free extract 92.0 per cent. The advisability of drying potatoes for fodder in times of overproduction is discussed.

Sugar-cane fodder, L. ACUTT (*Agr. Jour. and Min. Rec. [Natal]*, 5 (1902), No. 10, pp. 319-321).—According to the author, who discusses sugar cane growing for forage, this material is a useful feeding stuff, especially for winter. If the cane has been touched by frost, he believes that it should be harvested and the harder portions cut with a chaff cutter, as this will not keep for any length of time, while the balance of the crop should be stacked. It is stated that cattle are very fond of old cane tops.

Concerning sunflower-seed cake, R. WINDISCH (*Landw. Vers. Stat.*, 57 (1902), No. 3-4, pp. 305-316).—The author reports analyses of sunflower seed, cake and hulls, and discusses these figures and those obtained by other investigators.

Fodder value of barley grass, F. B. GUTHRIE and A. A. RAMSAY (*Agr. Gaz. New South Wales*, 13 (1902), No. 3, pp. 309-311).—An analysis of this grass is reported.

The progress of protein cleavage when the diet supplies an abundance of protein, O. FRANK and R. TROMMSDORFF (*Ztschr. Biol.*, 43 (1902), No. 2, pp. 258-287).—In experiments with a dog the authors studied the excretion of nitrogen and carbon dioxid when the diet supplied an abundance of protein, especial attention being paid to the variations observed when the diurnal excretion was considered by short periods.

Concerning the cleavage of carbohydrates by animal ferments, plant ferments, and enzymes, W. N. CLEMM (*Arch. Physiol. [Pflüger]*, 89 (1902), No. 9-10 pp. 517-526).—Digestion experiments with saliva ptyalin, pancreas extract, pancreatin, pig and dog liver ferments, and diastase extract, led to the conclusion that pancreas ptyalin formed more than one sugar from starch, and that the sugars formed were different from those produced by the action of saliva ptyalin.

The behavior of glycogen in boiling potassium hydroxid solution, E. PFLÜGER (*Arch. Physiol. [Pflüger]*, 92 (1902), No. 3-5, pp. 81-101).—According to the author's investigation glycogen can be heated for a number of hours at 100° in strong potassium hydroxid solution without undergoing decomposition. On the other hand glycogen prepared by the Brücke-Külz method was partially decomposed when heated in dilute potassium hydroxid solution.

Concerning the glycogen content of the cartilage of vertebrates, E. PFLÜGER (*Arch. Physiol. [Pflüger]*, 92 (1902), No. 3-5, pp. 102, 103).—The author reports the quantitative estimation of glycogen in fresh horse cartilage.

Contribution to the subject of the glycogen content of the skeleton, M. HÄNDEL (*Arch. Physiol. [Pflüger]*, 92 (1902), No. 3-5, pp. 104-114).—Experiments with the bones, sinews, and cartilage of a dog and with the marrow and other parts of the bones and also with the sinews and cartilage of a steer, are reported. In the case of the steer the amount of glycogen varied from 0.0059 per cent in sinew to 0.2168 per cent in cartilage. The dog bones were found to contain 0.008 per cent, the sinew 0.030 per cent, and the cartilage 0.160 per cent glycogen. According to the author all portions of the skeleton contain glycogen which can be extracted with potassium hydroxid solution. The glycogen may be precipitated with alcohol and the precipitate is not flocculent. The amount of glycogen in bones and sinews is very small; the amount in cartilage is considerably larger.

Concerning the saponification which is brought about by gall and the estimation of soaps in the presence of fatty acids in gall mixtures, E. PFLÜGER (*Arch. Physiol. [Pflüger]*, 90 (1902), No. 1-2, pp. 1-32).—A contribution to the study of the assimilation of fat (E. S. R., 13, p. 775). Experimental methods are described and results obtained are reported.

The physiological action of formaldehyde, W. KOCH (*Amer. Jour. Physiol.*, 6 (1902), No. 5, pp. 325-329).—From experiments which are reported, the conclusion was drawn that trypsin "like a starch or fat splitting enzyme, is not directly affected by formaldehyde. . . . Fibrin, on the other hand, is rendered more or less indigestible, depending on the strength of the formaldehyde and the time of exposure. We may conclude from this that formaldehyde does not act by forming active oxygen, nor by destroying the zymase, but brings about the death of the cell indirectly by rendering its proteid food supply useless and by preventing the digestion of proteids always going on within the protoplasm of the cell, a reaction intimately connected with the life of the organism."

Concerning the modifications which warm and moist surroundings produce in the respiratory quotient, V. GRANDIS and C. MAININI (*Arch. Ital. Biol.*, 37 (1902), No. 2, pp. 281-297, fig. 1).—The results of experiments with small animals and pigeons are reported.

Market classes and grades of cattle, with suggestions for interpreting market quotations, H. W. MUMFORD (*Illinois Sta. Bul.* 78, pp. 367-433, figs. 48).—On the basis of an extended study of the subject in the Chicago Union Stock Yards the author discusses the principal classes of cattle and grades in which the classes are subdivided commercially, the purpose of the bulletin being to familiarize feeders and breeders of beef cattle with the market conditions. The importance of such a classification is shown by the fact that hitherto there has been no uniformity in the use of terms by those who raise and sell cattle or report market transactions in them. Recognizing the fact that in the nature of the case any classification must be more or less arbitrary, the following is submitted, which in the author's opinion represents the distinction actually made:

Market classes and grades of cattle.

CLASSES.

Beef cattle:

Prime steers.
Choice steers.
Good steers.
Medium steers.
Common rough steers.

Butcher stock:

Prime heifers.
Choice heifers.
Good heifers.
Medium heifers.
Prime cows.
Choice cows.
Good cows.
Medium cows.
Common rough steers.
Choice bulls.
Good bulls.
Medium bulls.

Cutters and canners:

Good cutters.
Medium cutters.
Common cutters and good canners.
Medium canners.
Inferior canners.
Bologna bulls.

Stockers and feeders:

Fancy selected feeders.
Choice feeders.
Good feeders.
Medium feeders.
Common feeders.
Inferior feeders.
Feeder bulls.
Fancy selected yearling stockers.
Choice yearling stockers.
Good yearling stockers.
Medium yearling stockers.
Common yearling stockers.
Inferior yearling stockers.
Good stock heifers.
Medium stock heifers.
Common stock heifers.

Veal calves:

Choice.
Good.
Medium.
Common.

SUBCLASSES.

Texas and Western range cattle.

Distillers.

MISCELLANEOUS.

Baby beef.

Dress beef cattle.

Export cattle.

Stags.

Shipping steers.

The different classes and grades are discussed and described. Some of the author's deductions follow:

"The names of the various classes indicate the uses to which cattle in those classes are put. The grades refer to quality, condition, and conformation, the relative importance of which factors, so far as they influence market values, is indicated by the order in which they have been enumerated, quality being of greatest importance, condition next, and conformation of least importance. Weight has relatively but small influence in determining the grade and price of fat cattle. Quality and condition largely govern both.

"[The producers should] become thoroughly familiar with the characteristics of prime steers and choice feeders; these are the standard grades of fat cattle and feeders. Fluctuations in the market affect these grades less than others. It is, therefore, more difficult to determine an approximately correct valuation for a lot of low-grade cattle than for cattle of higher grades.

"The terms export, shipping, and dressed beef steers are no longer significant of any particular grade of cattle. Several different grades and even different classes are exported, shipped, and used for dressed beef. The most desirable steer for export, for shipping, and for the best grades of dressed beef either for domestic or foreign trade is the same in each instance. The best grade of any class of cattle must be practically above criticism.

"When cattle grade the best of their class they command a premium on the market. Such cattle usually sell at strong prices and for their full value. Cattle of the lower grades, necessarily deficient in certain particulars, sell at a discount, which in many instances is greater than their inferiority demands. Thus it will be seen that the tendency is to spring the market for choice, prime, and fancy grades while the common and medium grades are seldom, if ever, sold for more than they are worth, and many times they do not bring their full value owing to a tendency on the part of buyers to magnify defects of minor importance."

Feeding native steers, A. M. SOULE and J. R. FAIN (*Tennessee Sta. Bul. Vol. XV, No. 3, pp. 111-140, figs. 14*).—Continuing previous work on the possibility of profitably feeding native Tennessee steers (*E. S. R.*, 13, p. 76), 3 tests were made to compare dry and succulent rations, cowpea hay and cotton-seed meal, and to learn the relative merits of cotton-seed meal and cotton-seed bran. The lots used in the 3 tests were numbered consecutively. In the first test, which was made in 1900, 2 lots of 4 steers each were fed corn meal and corn stover, lot 1 receiving cowpea hay in addition and lot 2 a mixture of cotton-seed meal and cotton-seed bran.

Three lots of 4 and 1 of 3 steers were used in the second test, which was carried on in 1901. All the lots were fed corn meal. In addition, lots 3 and 5 were fed cowpea hay and lots 4 and 6 cotton-seed meal. Lots 3 and 4 were also fed corn stover and lots 5 and 6 silage; for 60 days this consisted of corn and during the remainder of the test of sorghum.

The test in 1902 was also made with 3 lots of 4 and 1 of 3 steers. The grain ration of lots 7 and 8 consisted of corn meal and cotton-seed meal, 1:2; that of lots 9 and 10 of cotton-seed meal and cotton-seed bran, 52:48. In addition to corn, lots 7 and 9 were fed cowpea hay and silage, and lots 8 and 10 cowpea hay and corn stover. After 30 days the feeding of cotton-seed meal to lots 9 and 10 was discontinued and

the amount of cotton-seed bran was increased. The first test covered 91 days and the other 2 tests 120 days each, tests 1 and 2 being preceded by a preliminary period of 7 days and test 3 by a preliminary period of 14 days. At the beginning of the test the average weight of the steers in lots 6 and 10 was 2,648 lbs. and 2,386 lbs., respectively. The steers in the other lots weighed on an average from about 3,200 to 3,500 lbs. each. At the close of the test the steers were slaughtered and the quality of the beef judged. The following table shows the principal results of the tests:

Results of feeding native steers.

	Average daily gain per steer.	Feed eaten per pound of gain.						Net cost of a pound of gain.		Good cuts in carcass.
		Corn silage.	Corn stover.	Cow-pea hay.	Cotton-seed bran.	Cotton-seed meal.	Corn meal.	Rating feeds at high prices.	Rating feeds at low prices.	
Test 1:	Lbs.	Lbs.	Lbs.	Lbs.	Lbs.	Lbs.	Lbs.	Cts.	Cts.	Per ct.
Lot 1.....	1.8	2.2	4.8	3.7	5.2	3.6	53.0
Lot 2.....	1.6	2.2	6.0	2.5	1.4	6.9	6.2	52.2
Test 2:										
Lot 3.....	1.3	4.3	6.0	4.8	6.6	4.3	55.3
Lot 4.....	1.1	6.6	2.3	5.6	6.9	5.0	57.1
Lot 5.....	1.5	21.4	2.3	4.2	6.1	4.2	56.2
Lot 6.....	2.1	18.7	1.3	3.2	4.7	3.5	57.5
Test 3:										
Lot 7.....	1.9	14.6	2.3	2.0	2.1	6.0	5.0	56.5
Lot 8.....	1.5	3.8	4.0	2.5	2.7	7.0	5.4	55.2
Lot 9.....	1.4	20.3	3.6	2.1	3.2	6.5	5.6	54.6
Lot 10.....	1.2	4.3	5.5	2.5	3.7	6.3	5.2	53.9

The average amount of water consumed per head daily ranged from 23.8 lbs. with lot 6 to 54.9 lbs. with lot 10. The authors discuss the amount which the steers lost in driving them 2 miles to the stock yards and slaughtering, and record the weight of the liver and intestinal fat. Estimates are also made of the cost of feeding and care, taking into account the value of the manure produced and also the profits obtained. Rating feeding stuffs at high prices the least profit, \$2.09, per head was obtained with lot 2, and the greatest profit, \$7.83, with lot 10. Rating feeding stuffs at low prices the least profit, \$3.06, was obtained with lot 2, and the greatest profit, \$9.38, with lot 7.

"Leaving out of consideration the preliminary feeding, very satisfactory gains can be made with native cattle, varying from 1.2 to 2.1 lbs. per head per day, depending largely on the character of the ration fed. With 6 of the groups a gain of practically 1.5 lbs. per day was made throughout the entire feeding period."

The results obtained with silage, cotton-seed meal, and corn meal, according to the authors, show that this ration was the most satisfactory as regards palatability and gains made, and it is regarded as the best ration for the average Southern farm. The tests indicate that cowpea hay can frequently be substituted to advantage for cotton-seed meal. Some 6 to 10 lbs. of cowpea hay was satisfactorily substituted in the above test for some 3 to 5 lbs. of cotton-seed meal.

"As large crops of pea hay can be cheaply produced in the South, it can frequently be utilized to advantage in place of corn and cotton-seed meal, especially when these concentrates are high priced. Pea hay can not be so successfully substituted for cotton-seed meal where a succulent ration is fed as a dry ration."

Succulent rations gave better results than dry rations, the total gain on the former being 761 lbs. more than on the latter. The former was also found to be more profitable.

"The average results of two years' trials on the University farm show that about 7.8 tons of corn silage and 7.2 tons of sorghum silage can be obtained per acre. The cost of corn silage is \$17.08 and the sorghum silage \$12.81 per acre. Silage from

either source is equally satisfactory as a roughness for beef cattle, though owing to the fact that sorghum silage can be grown as a 'second crop' it can be produced for some less than the corn silage. Stover is not as satisfactory a roughness as silage."

According to the authors cotton-seed bran did not prove satisfactory when fed alone as a coarse fodder or when substituted for 48 per cent of the cotton-seed meal in a ration.

"The farmer can produce his own roughness for less than he can buy it, and it will always be to his interest to buy the pure cotton-seed meal. . . . The average slaughter test of the dry-fed cattle was 55.4 per cent, and of the succulent-fed cattle 56.4 per cent. The weight of good meat in the carcass of the dry-fed cattle was 8,106 lbs., and in the succulent-fed cattle 8,683 lbs., a difference of 577 pounds of salable meat in favor of the succulent-fed cattle. The necessity of improving our native stock is shown by the slaughter test, which was about 55 per cent for all the groups. The average cattle slaughtered in Southern abattoirs do not dress over 50 per cent, whereas they should dress 60 per cent with animals of the weight and size of those considered in the experiments of 1902. This would amount to a loss of 96.2 lbs. per head, which at a selling price of 8 cts. per pound means a loss of \$7.70 per animal."

In the authors' opinion a number of the lots could have been profitably fed for a longer period.

Feeding experiments, E. R. LLOYD (*Mississippi Sta. Rpt. 1902, pp. 16-18*).—Brief notes are given regarding the feeding of cows, beef cattle, mules, and sheep at the station. Using 2 lots of mules, the feeding value of cotton-seed meal as part of the ration was tested, 1 lot being fed wheat bran and cotton-seed meal 3:1 and the other bran and cotton-seed meal 1:1. The mixtures were eaten sparingly at first and at the end of 6 weeks were practically refused. It was thought this might have been due to the fact that the mules had not been accustomed to wheat bran, and corn chops was, therefore, substituted for it; but, according to the author, they still refused to eat enough of the mixture to keep them in good working condition, and at the end of 90 days they were losing flesh so rapidly that the cotton-seed meal was discontinued.

Statistics are given regarding the station flock of sheep. The average cost of wintering was 99 cts. per animal, the ration fed consisting of cotton-seed meal, cotton-seed hulls, and shredded corn fodder. The feeding experiments with cows are more extensively noted elsewhere (p. 606). The test with beef cattle has been reported in a previous publication (E. S. R., 14, p. 483).

Cattle rearing in Egypt, J. L. SMITH (*Jour. Khediv. Agr. Soc. and School. Agr., 4 (1902), No. 4, pp. 161-165*).—The author discusses the conditions and requirements for successful cattle raising under local conditions.

Swine feeding in Colorado, B. C. BUFFUM and C. J. GRIFFITH (*Colorado Sta. Bul. 74, pp. 29, figs. 2*).—With a view to learning the possibilities of pig raising in Colorado, where large corn crops are not grown, 4 tests were made of the feeding value of sugar beets, sugar-beet pulp, and alfalfa, and of barley and other local grown grains as compared with corn. As pointed out by the authors, the sugar-beet crop and the alfalfa crop in Colorado are very large, and great quantities of sugar-beet pulp are available for feeding should it prove satisfactory. An analysis of the pulp is quoted.

The first of the tests reported was made with 5 lots each containing 4 grade pigs, averaging not far from 100 lbs. in weight at the beginning of the trial. Lot 1 was fed chopped sugar beets only, lots 2, 4, and 5 ground wheat and barley, 1:1, and lot 3 shelled corn. In addition, lot 2 was fed beet pulp and lot 5 sugar beets. The test covered about 100 days. The average daily gain per pig in the 5 lots was 0.17, 0.89, 0.70, 1.16, and 0.94 lbs., respectively, the cost of a pound of gain being 12.3, 4.3, 7, 4.5, and 5 cts. Lots 1, 3, and 4 required respectively 10.37 lbs. of sugar beets, 3.8 lbs. of corn, and 5.25 lbs. of the wheat and barley mixture per pound of gain. Lot

2 required 7.1 lbs. of sugar-beet pulp and 3.46 lbs. wheat and barley mixture, while lot 5 required 3.76 lbs. of sugar beets and 4 lbs. of the same grain. In lot 1 the dressed weight was 77 per cent of the live weight. In the case of lots 2 and 3, it was 80 per cent and in case of lots 4 and 5 it was 84 per cent. Rating pork at 6 cts. per pound there was a loss of \$1.04 and 71 cts. in lots 1 and 3, and a profit of \$1.50, \$1.75, and 96 cts., respectively, in lots 2, 4, and 5. Rating pork at 7 cts. per pound, there was a profit of 13 cts., \$3.35, 95 cts., \$3.90, and \$2.93, in the 4 lots respectively.

The second test was made with 9 Berkshire pigs divided into 3 lots of 3 each, averaging about 150 lbs. in weight at the beginning of the trial. Lot 1 was fed alfalfa hay, corn, and barley, consuming 0.49, 3.72, and 1.72 lbs. per pound of gain, respectively. Lot 2 was fed corn and barley, the amounts required per pound of gain being 3.63 and 1.65 lbs. Lot 3 was fed corn, barley, and sugar beets, requiring 3.64, 1.91, and 1.03 lbs. per pound of gain. In the 95 days of the test the average daily gain per pig in the 3 lots was 1.13, 1.08, and 0.99 lbs., and the cost of a pound of gain 4.9, 4.6, and 5.2 cts. The calculated profit, rating pork at 5 cts. per pound, was \$1.73, \$1.94, and \$1.26. The dressed weight of the pigs in lot 1 averaged 86.1 per cent of the live weight. The values for the other 2 lots were very similar, being 87.4 per cent for lot 2 and 87.1 per cent for lot 3.

The third test reported was made with 4 lots of Berkshire pigs, lot 2 containing 2 animals and the other lots 3, the average weight at the beginning of the trial for the 4 lots being 164.5, 104, 112.5, and 98 lbs., respectively. In the 69 days covered by the test the pigs in lot 1 made an average daily gain of 0.98 lb. on a ration of corn only, consuming 6.43 lbs. per pound of gain. In the case of lot 2 the gain was 1.11, the food eaten per pound of gain being 3.08 lbs. corn and 3.01 lbs. shorts. In the case of lot 3, the average daily gain was 1.31 lbs., the food required per pound of gain being 2.61 lbs. of shorts, 0.88 lb. wheat, 0.85 lb. oats, and 0.87 lb. barley, the grains being so rotated that shorts were fed with wheat and oats on 1 day, with wheat and barley the next, and with oats and barley the next. With lot 4 the average daily gain was 1.27 lbs. and the food eaten per pound of gain, 2.43 lbs. corn, 0.84 lb. wheat, 0.80 lb. oats, and 0.80 lb. barley, the corn being rotated with the other grains, as in lot 3. The average cost of a pound of gain in the 4 lots was 5.3, 4.8, 4.7, and 4.7 cts., respectively, and the total profit per lot, rating pork at 5 cts. a pound, \$1.41, \$1.18, \$0.69, and \$1.19. The dressed weight in the 4 lots was 78.6, 77.4, 81.6, and 79.2 per cent of the live weight, respectively.

The principal deductions drawn from these tests as a whole follow:

"Home-grown grains fed in proper proportion to balance the ration are more valuable than corn.

"A well balanced ration gives better returns in every case than a poorly balanced ration, and a mixture of grains is better than a single grain fed alone.

"Sugar beets for swine feeding were unprofitable with us, either fed alone or in combination with grain. Green pasture would probably serve the purpose of furnishing succulent food for growing pigs at less expense.

"Sugar beets are little more than a maintenance ration when fed alone to hogs.

"Sugar beets and sugar-beet pulp proved equally valuable in our experiments, and because of its cheapness and effect on growth we believe pulp may be profitable to feed to growing pigs in connection with a grain ration, or during the first part of a fattening period.

"These experiments indicate that sugar beets may have a value of about \$1.50 per ton when fed to hogs in combination with grain. Beet pulp gave a return of \$1.50 per ton when fed in combination with grain.

"Sugar-beet pulp served the same purpose in our hog rations as did sugar beets and at less expense. It was necessary to mix beet pulp with grain in order to educate the pigs to eat it. We would not recommend feeding more than 2 lbs. of pulp to 1 lb. of grain in a ration for pigs which are from 100 to 200 lbs. in weight.

Our trials indicate that pigs take some of the nutritive property from beets, but their principal use, as well as that of pulp, seems to be mechanical.

"Dry alfalfa hay as roughage may be made use of by the growing pigs. In our trials the pigs ate more grain and made more gain than on a similar grain ration minus the alfalfa.

"Comparing our results with pig feeding experiments in other States, indicates that our small grains, more especially our barley and wheat, are worth more compared with corn than similar grains raised under rainfall conditions.

"Mixed wheat and barley ground together make a well balanced ration for pigs and one upon which they will make better growth and gain than they will on a ration composed of corn alone. The farmer in Colorado can not ordinarily afford to sell his home grown grain and purchase corn for fattening hogs. Wheat and barley in equal parts were worth 17 per cent more than corn fed alone."

The influence of condimental stock food in fattening swine, C. S. PRUMB (*Indiana Sta. Bul.* 93, pp. 117-123).—The first of the 2 tests reported was made by H. E. Van Norman, with 8 pigs divided into 2 lots of 4 each. Lot 1 was fed shorts and hominy feed 1:1 with 2.1 oz. of American Stock Food per head daily in addition. Lot 2 was fed the same grain ration but no stock food. The average weight of the pigs in the beginning of the test, which covered 122 days, was 65 and 64 lbs. respectively. The average daily gain per pig was 1.42 and 1.43 lbs.; the food eaten per pound of gain, 3.84 and 3.71 lbs., and the cost of food per pound of gain, 3 cts. and 2.6 cts., respectively. According to the author, the best results were obtained without condimental feed.

Two lots of 3 grade pigs each, weighing on an average 63 lbs. each, were used in the second test which was carried on by C. W. Ely. Each lot was fed corn meal and shorts 1:1. In addition the pigs in lot 1 were fed 0.4 oz. per head daily of Raub's Stock Food during the first 5 weeks of the test and during the last 7 weeks of Standard Stock Food. The average daily gain of the 2 lots was 1.6 and 1.5 lbs., respectively; the feed eaten per pound of gain, 3.51 and 3.62 lbs., and the profits on the 2 lots \$6.98 and \$6.50 respectively. In this test a somewhat greater profit was obtained with the lot given condimental food.

"In themselves, there is no special objections to stock foods. In fact there are brands made that are rich in nutriment, and have a high value as a food. The principal criticism that can be made is the excessive price generally charged for them, which is far beyond their value. No doubt, in many cases oil meal will give fully as satisfactory results as the stock food. The feeder should study this matter carefully, and if he will use a variety of food, including oil meal, and will ascertain the value of some of the more common tonics that may be given stock in the foods, he will secure no doubt equally good results at the least cost. He will in fact be able to make his own stock food, and thus save paying high prices for feed of an unknown character."

Giant lily as a food for pigs (*Agr. Gaz. New South Wales*, 13 (1902), No. 2, pp. 255, 256).—It was found that pigs would readily eat giant lily bulbs (*Dyanthes excelsa*), if they were cooked and a little ground maize added. An analysis of the bulbs is reported.

Organized poultry work in England, G. M. CURTIS (*Reliable Poultry Jour.*, 9 (1902), No. 8, pp. 706-709, figs. 9).—A description of the poultry farm at Reading College, England, and the instruction which is given in poultry raising.

Scientific studies of oyster propagation, J. NELSON (*New Jersey Stat. Rpt.* 1901, pp. 307-351, pl. 1, figs. 8).—A description is given of the author's experiments on the artificial propagation of oysters with special reference to the fertilization of the egg. The time after fertilization at which the developmental changes occur in oyster eggs at different air temperatures is noted. The figures obtained show that the changes became greater as the temperature increased. Some irregularities are discussed.

"We know from this and from previous reports that the eggs of any one oyster do not all develop at the same rate, and that the vigor of all the eggs in an oyster rapidly declines after the oyster is removed from its native element. We also have abundant evidence that oysters differ greatly in the character and fertility of their eggs, even when first taken from the water.

"Again, we have, in this and previous reports, shown that the rate of development is dependent upon the supply of oxygen and the extent to which the eggs are stirred and crowded.

"Again, the various events are not sharp ones, but each occupies some time, beginning and ending with imperceptible changes and progressing to a climax gradually. It is difficult to observe the changes of similar phases in different lots of eggs.

"Finally, the temperature of the water is not equally a fixed number of degrees below that of the air. Also, the temperatures given [as part of the experimental data] are those obtaining at the beginning of each experiment, and therefore not accurately the average temperature in each experiment.

"These facts must all be considered in a set of experiments, in which conclusions are made, based on the variations in the rate of development. But, undoubtedly, the rate of development is an important index to the vigor and character of the spawn, and may, perhaps, come to figure prominently in a practical system of oyster propagation. Therefore, studies along this line can not be ignored during this, the experimental period of scientific oyster propagation."

DAIRY FARMING—DAIRYING.

Dairy husbandry, H. J. WATERS and C. H. ECKLES (*Missouri Sta. Bul.* 56, pp. 31, figs. 6).—This bulletin is issued with a view to awakening an interest in dairying in Missouri and disseminating reliable information on the subject. The introductory part, by H. J. Waters, contains a brief description of the new dairy building and the text of the State law establishing a chair of dairy husbandry in the College of Agriculture. The main part of the bulletin, by C. H. Eckles, deals with the dairy and crop production in Missouri, the adaptability of the State to dairying, the income from average and selected herds, the comparative profits in selling milk to creameries and cheese factories, dairying as a means of keeping up the fertility of the farm, the labor problem involved in dairying, the use of the hand separator on the farm, private and cooperative dairying, and other topics.

Missouri is considered well adapted to dairying on account of its mild climate, long pasturing season, productive soil, and good markets for dairy products. Estimates place the annual income of the average creamery patron in Missouri at \$29.32 per cow. The income received from the creamery in 8 selected cases ranged from \$37.14 to \$61.23. Special attention is called to the fertilizing value of some of the farm products that are commonly sold from the farm and which may be utilized in dairying. The author believes that within a few years the hand separator will be considered as necessary a farm machine as the mower or harvester.

Report of the assistant in dairy husbandry, C. B. LANE (*New Jersey Stat. Rpt.* 1901, pp. 269-303, pls. 16).—An outline is given of the dairy work during 1901, which was along the lines followed in previous years and reported upon in the annual reports of the stations.

Soiling crops (pp. 272-278).—Notes are given on the 15 forage crops grown for soiling purposes during the year. A brief description is given of a cutaway, having 5 turning disks 24 in. in diameter and 5 smaller disks. The machine is drawn by 4 horses and is considered particularly valuable in preparing ground which has become too hard to plow. A good crop of hay was secured from seeding to grass without grain the previous fall.

Experiments with feeding oat and pea feed and straw v. oat and pea hay (pp. 278-284).—Oat and pea straw and oat and pea feed combined was compared with oat and pea hay in rations containing silage and cotton-seed meal in addition. The protein and fat were practically the same in both rations. The hay ration contained more dry matter and carbohydrates. The test was made with 2 lots of 2 cows each and lasted 30 days. The straw and feed ration produced 2.6 per cent more milk and 5.96 per cent more fat than the hay ration. The cost of milk production on the 2 rations was respectively 61.6 cts. and 49.9 cts. per 100 lbs., and the cost of butter production 11.9 and 10 cts. per pound. The hay ration, though producing less milk, was more profitable. A greater gain in live weight was also made on this ration.

Farm roads (pp. 284, 285).—Roads were constructed of (1) cinders, (2) cinders and gas lime, and (3) cinders and stone lime. The road constructed of cinders alone was always dry and stood traffic well for a short time but needed frequent repairs. The road constructed of gas lime and cinders in the proportion of 1 to 5 has been in use for 3 years and required no repairs. The odor of the lime is considered the only objection to this form of farm road. The use of slaked lime in place of gas lime, while more expensive, has given equally good results, without the presence of the disagreeable odor.

Description of the new wing of the dairy barn (pp. 286, 287).—The building is a one story frame structure 32 by 38 ft. providing stalls for dairy cattle.

Cost of producing milk (pp. 287-290).—Data for the cost of producing milk during the year are given and compared with similar data for previous years. The average cost of milk production for 5 years, including food, labor, and interest and decrease in the value of the herd, was 2.38 cts. per quart.

Soiling crop rotation (pp. 291-293).—Tabulated data are given for the various combinations of crops supplying forage to the dairy herd from May 1 to November 1.

Dairying in relation to soil exhaustion (pp. 293-295).—The amounts of fertilizing elements contained in the feeds purchased and in the milk produced by the dairy herd for 5 years are shown in tabular form. The total gain in fertilizing elements to the farm is estimated as equivalent to the nitrogen in 18.5 tons nitrate of soda, the phosphoric acid in 20.4 tons acid phosphate, and the potash in 1.78 tons of high grade muriate of potash. If no feeds had been purchased the exhaustion of nitrogen would have been in greater proportion than the mineral elements.

Record of dairy herd (pp. 295-303).—A monthly record of 26 cows is given for the year ended April 1, 1901. The average yield of milk per cow was 6,545 lbs. and the average fat content of the milk 4.29 per cent. The waste in handling and delivering milk during the year was 5.5 per cent.

Alfalfa, cowpeas, and crimson clover as substitutes for purchase feeds. Home-grown protein v. purchased protein, C. B. LANE (*New Jersey Stats. Bul.* 161, pp. 23, pls. 4).—In 3 feeding experiments which are reported in detail comparisons were made of home-grown rations and rations containing purchased feeds.

Alfalfa hay v. purchased feeds (pp. 4-11).—The alfalfa hay ration consisted of 13 lbs. of alfalfa hay and 30 lbs. corn silage, and the feed ration of 5 lbs. mixed hay, 30 lbs. corn silage, 6 lbs. wheat bran, and 5 lbs. dried brewers' grains. The 2 rations contained practically the same amount of protein. The nutritive ratios were 1:5 and 1:6.1 respectively. The test was made with 2 lots of 2 cows each and lasted 32 days. The feed ration produced 4.15 per cent more milk and 4.16 per cent more butter than the alfalfa ration. The fat content of the milk was the same for both rations. The cost of producing 100 lbs. of milk on the alfalfa ration was 55.9 cts., and on the feed ration 83.9 cts., and the cost of producing 1 lb. of butter on the 2 rations was respectively 11.1 and 16.7 cts. While more milk was produced on the feed ration, the alfalfa ration was more profitable. A greater gain in live weight was made on the alfalfa ration. Alfalfa is therefore considered a valuable crop for dairy purposes.

Crimson clover hay v. purchased feeds (pp. 11-16).—The crimson clover ration contained 60.4 lbs. crimson clover hay and 30 lbs. corn silage. The feed ration was the same as in the preceding experiment. The 2 rations contained the same amount of protein and had nutritive ratios of 1:5.7 and 1:6.1. The test, made with 2 lots of 2 cows each during a period of 30 days, showed that 18.1 per cent more milk was produced on the feed ration. The cost of producing 100 lbs. of milk on the crimson clover ration was 71.2 cts. and 1 lb. of butter 14.46 cts., the corresponding figures for the feed ration being 89.5 and 18.19 cts., respectively. The saving in the cost of food when the crimson clover ration was fed was more than equal to the increased yield when the feed ration was used. The increase in the live weight of the animals was greater on the crimson clover ration. This crop has been grown successfully at the station for a number of years.

Cowpea silage and crimson clover hay v. purchased feeds (pp. 16-23).—The home-grown ration contained 36 lbs. cowpea silage, 10 lbs. crimson clover hay, and 6 lbs. corn-and-cob meal, and the feed ration, 36 lbs. corn silage, 5 lbs. mixed hay, 4 lbs. dried brewers' grains and 2.5 lbs. cotton-seed meal. As in the previous experiments the test was made with 2 lots of 2 cows each and lasted 30 days. The 2 rations were practically identical as regards nutrients. The yield of milk and butter on the 2 rations was practically the same. The cost of producing 100 lbs. of milk was 66.9 cts. on the home-grown ration, and 69.9 cts. on the purchased feed; and the cost of producing 1 lb. of butter was 15.1 and 14.9 cts. respectively. The home-grown ration was considered therefore equally as good as the purchased ration. The composition of foddere and feeds used in the experiments is shown in a table.

The relative value of protein in cotton-seed meal, cowpea hay, and wheat bran. A. M. SOULE and S. E. BARNES (*Tennessee Sta. Bul. Vol. XVI, No. 4, pp. 143-163, figs. 8*).—Dairying in the South is discussed to some extent in this bulletin, and a cooperative experiment between the station and the Bureau of Animal Industry of this Department is reported. The purpose of the experiment was to compare different combinations of cotton-seed meal, cowpea hay, and wheat bran as sources of protein. Three lots of 4 cows each were fed experimentally for 4 months. The daily ration for all animals included 30 lbs. of silage. In addition, lot 1 received 4 lbs. of cotton-seed meal and 6 lbs. of wheat bran; lot 2, 4 lbs. of cotton-seed meal and 7 lbs. of cowpea hay; and lot 3, 6 lbs. of wheat bran and 13 lbs. of cowpea hay. The 3 rations furnished the same amount of protein and were satisfactorily eaten by the cows.

Lot 1 consumed 25,415 lbs. of silage, 2,880 lbs. of wheat bran, and 1,920 lbs. of cotton-seed meal; lot 2, 23,795 lbs. of silage, 3,034 lbs. of cowpea hay, and 1,920 lbs. of cotton-seed meal; and lot 3, 15,531 lbs. of silage, 4,935 lbs. of cowpea hay, and 2,880 lbs. of wheat bran. Lot 1 gained 41 lbs. and lot 2, 7 lbs. in live weight during the 4 months, and lot 3 lost 190 lbs. The milk produced by the 3 lots was, respectively, 9,134, 7,833, and 7,176 lbs., and the fat produced, 447.59, 415.15, 394.68 lbs. "It appears that all the foods were satisfactory in maintaining a good flow of milk, a high fat content, and a high percentage of total solids, and the variations shown are not definite enough to attribute the results to any material influence of the respective feeds." The digestible matter consumed by the 3 lots for the production of a gallon of milk was, respectively, 6.2, 6.5, and 7.2 lbs., and for the production of a pound of butter, 12.7, 12.4, and 13.1 lbs.

In preparing a financial statement, both high and low prices of feeding stuffs are taken into account, as well as the fertilizing value of the manure. With high prices, the net cost of milk production by the 3 lots was, respectively, 6.7, 5.6, and 8 cts. per gallon, and with low prices, 4, 3.5, and 4.4 cts. The net cost of butter production with high prices was 13.8, 10.7, and 14.5 cts. per pound, and with low prices, 8.4, 6.7, and 7.9 cts.

"The results throughout favor the combination of cowpea hay and cotton-seed meal, two rich protein-containing foods, whether high prices or low prices are considered, for milk and butter making. They indicate also that at low prices cowpea hay can be substituted for cotton-seed meal with satisfactory results, whereas this can not be done when high prices prevail." The following statement is taken from the rather extended summary of the results: "Providing the palatability and the digestibility of the foodstuffs used are equal, the source from which the protein is derived has but little effect if the substitution of one food for another is made on the basis of the protein equivalent."

Apple pomace a good feed for cows, J. L. HILLS (*Vermont Sta. Bul. 96, pp. 7*).—The attention of Vermont dairymen is called to the feeding value of apple pomace for cows. In experiments at the station during 4 years this material has been tested, the results being uniformly in its favor and indicating that apple pomace has practically the same feeding value as corn silage. A brief summary is given of the experiments, which have been reported in detail in the reports of the station.

"These repeated experiments seem to be sufficient to demonstrate the value of this usually despised product. Twenty or more cows have been in four different years fed from 10 to 16 lbs. daily. Some were fed in 4-week periods, alternated with corn silage, and two were fed for 20 weeks continuously without trouble of any kind being experienced in the health of the animals or the quality of their products."

On account of unfavorable results which have been reported it is advised that a change from corn silage to apple pomace be made gradually. No special care has been observed at the station in ensiling apple pomace. The material has been dumped into the silo, leveled off, and left uncovered and unweighted until used. The station has fed 15 lbs. daily per cow with entire satisfaction.

Feeding experiments, J. S. MOORE (*Mississippi Sta. Rpt. 1902, pp. 23-26*).—Johnson grass hay was compared with corn silage and with cotton-seed hulls in 2 series of experiments which are reported. Six cows were used in each test, which lasted about 10 weeks. The results are summarized as indicating that under the conditions of the experiments 20 lbs. of corn silage is equal to about 6 lbs. of Johnson grass hay and 12 lbs. of cotton-seed hulls is equal to 10 lbs. of hay.

Record of dairy herd, J. S. MOORE (*Mississippi Sta. Rpt. 1902, pp. 19-22*).—This is a record of the amount and cost of food consumed and the milk and butter produced by 12 cows during the calendar year 1901. The average cost of food per cow was \$34.58, the average yield of milk 5,094.7 lbs., and the average yield of butter 325.6 lbs. The average cost of food for 100 lbs. of milk was 69.7 cts. and for 1 lb. of butter 11 cts.

Some of the influences affecting milk production, L. ANDERSON (*Thesis, Cornell Univ., 1902, pp. 97, figs. 13*).—The influences considered are natural environment, heredity, food, and the temperature of the cow, including oestrus and spaying. The part dealing with the influence of food was published as Bulletin 173 of the New York Cornell Station (E. S. R., 11, p. 1081). The author's investigations concerning the relation of the temperature of the cow to the secretion of milk are reported upon as a new line of study in the field of animal production. The records of the cows upon which the observations were made are given in tabular form and are also shown by means of diagrams. The conclusions drawn are as follows:

"The period of oestrus as observed with 11 cows was accompanied by little variation in the flow of milk; by a rise in butter-fat percentage in about one-half the cases and little or no change in the other half; by a variation in the total fat secreted corresponding to the variation in the percentage of fat; and usually by a rise in temperature. Each cow returned to her normal milk secretion as soon as the oestrus period had passed.

"Two cows that were spayed showed a large decrease in milk flow, a wide fluctuation in the percentage of fat, and a slight rise in temperature immediately following

the operation. Both cows recovered their normal condition and flow of milk within a few days.

"The results of a study extending over a period of 214 days of record with 14 different cows indicate that there is no intimate relation between the temperature of the cow and either the percentage of fat or the total yield of fat. There appears to be no difference in this respect whether the temperature be taken only at milking time or at more frequent intervals.

"In 214 days of record the lower percentage of fat for each day occurred 62 times with the smaller yield of milk and 149 times with the larger yield of milk; 50 times at the evening milking and 164 times at the morning milking; and 108 times with the smaller yield of fat and 106 times with the larger yield of fat.

"In 214 days of record with 14 different cows and comparing the morning's with the night's milking on each day, 51.6 per cent of the total butter fat produced was secreted at the milkings containing the higher percentage of fat, and 48.4 per cent of the total butter fat was secreted at the milkings containing the lower percentage of fat."

An extended bibliography is appended.

A study of some of the salts formed by casein and paracasein with acids: Their relations to American Cheddar cheese, L. L. VAN SLYKE and E. B. HART (*New York State Sta. Bul. 214, pp. 53-79*).—Introductory notes are given on the chemical changes taking place in cheese during the early stages of its manufacture, and experiments are reported the results of which are summarized by the authors as follows:

"(1) The object of the work described in this bulletin is to study the real function of acids in relation to the important changes taking place in cheese-curd during the Cheddar process of cheese-making.

"(2) In examining cheese for hetero-caseose by extraction with dilute solution of common salt, a body was found in quantities so large as to indicate that it was some compound other than hetero-caseose.

"(3) In studying cheeses made with and without the use of lactic acid, the salt-soluble product was discovered to be present in very large quantities only when acid was used, being practically absent, or present in very small proportions, when no acid was used.

"(4) In normal cheese the salt-soluble product is always found, but in varying quantities, being largest usually in new cheese, and diminishing with age of cheese. Various conditions affect the amount in new cheese, especially those conditions influencing the amount of acid present.

"(5) Paracasein, carefully prepared and treated with dilute lactic acid, furnishes a product resembling, in both physical and chemical properties, the salt-soluble substance extracted from cheese.

"(6) Paracasein is shown to combine with an acid in at least two different proportions, forming two distinct compounds; one is the unsaturated or mono-acid salt; the other, the saturated or di-acid salt. Such compounds were prepared with lactic, acetic, hydrochloric, and sulphuric acids.

"(7) Casein forms salts with acids in the same manner as paracasein.

"(8) The unsaturated salts formed by casein and paracasein with acids are soluble in dilute solutions of sodium chlorid and in 50 per cent hot alcohol, but insoluble in water. The saturated salts are practically insoluble in water, dilute salt-solutions and 50 per cent hot alcohol. Both forms are sparingly soluble in dilute solutions of calcium lactate and calcium carbonate.

"(9) The important changes taking place in cheese-curd during the process of Cheddar cheese-making, such as the acquired ability to form strings on hot iron, the changes in appearance, plasticity and texture, and probably the shrinkage, are due to the formation of the unsaturated paracasein lactate.

"(10) The ripening process in normal Cheddar cheese, by which the insoluble nitrogen-compounds change into soluble forms, begins, not with paracasein as has been universally held, but with unsaturated paracasein lactate. The water-soluble nitrogen in cheese generally increases as the unsaturated paracasein lactate decreases, and apparently at the expense of the latter compound. The first step in the normal ripening process of American Cheddar cheese is probably a peptic digestion of unsaturated paracasein lactate. Some of the facts presented suggest a method of proof of the commonly accepted theory of gastric digestion."

Milk in relation to public health, G. M. KOBER (*U. S. Senate, 57. Cong., 1. Session, Doc. 441, pp. 1+235, pls. XI*).—In this document the author defines what constitutes mechanically, chemically, and bacteriologically pure milk, discusses the importance of sanitary supervision of the production and sale of milk and cream, and presents in detail in a series of articles which are appended the results of his studies of milk in relation to public health. Appendix A deals with the influence of food, breed, and season upon the composition of milk, the adulteration and preservation of milk, and standards for dairy products. Appendix B is devoted to milk inspection, milk analysis, and the methods of detecting adulterations and the preservatives of milk. Appendix C discusses the dietetic and therapeutic uses of milk. Appendix D deals with the relation of bacteria to disease. Appendix E describes the cultivation and study of bacteria. Appendix F considers the relation of impure milk to infantile mortality. Appendix G is a reprint of an article by R. A. Pearson entitled *Market Milk: A Plan for Its Improvement* (*E. S. R., 13, p. 1083*). Appendix H deals with abnormal milk and the diseases traced to this source. Two bibliographies are included and tabulated data are given for epidemics of typhoid fever, scarlet fever, and diphtheria due to an infected milk supply.

The creamery patron's handbook (*Chicago: The National Dairy Union, 1902, pp. XIX+309, figs. 110*).—This book is made up of the following articles: The National Dairy Union and Its Work for the Protection of Pure Butter Against Oleomargarine Imitation, by C. Y. Knight; The Patron and the Creamery, by W. D. Hoard; Building up a Dairy Herd, with Suggestions on Midsummer Forage Crops, by C. F. Curtiss; Selection of Cows, by C. P. Goodrich; Stable Location, Construction, and Sanitation, by H. B. Gurler; The Comparative Value of Feeds, with Tables Giving their Percentage of Digestible Nutrients, by W. A. Henry; Management of Young Dairy Stock, with a Review of Some Interesting Calf Experiments, by D. H. Otis; Economic Feeding and Care of Dairy Cows, with Instructions and Examples of how to Formulate Dairy Rations, by T. L. Haecker; Commercial Feeding Stuffs, by W. H. Jordan; Tainted or Defective Milks, Their Causes and Methods of Prevention, by H. L. Russell; Milk and Its Production for Cities and Towns, by A. W. Bitting; Milking, Cooling, and General Care of Milk for Delivery to Creamery, by E. H. Farrington; Necessity of Making Good Butter and the Farmer's Part in Its Production and Sale, by J. Kolarik; Variation in Tests—Composition of Milk as Observed at the Model Dairy at the Pan-American Exposition at Buffalo, N. Y., by DeW. Goodrich; Breeds of Cows—Views on the Building up of a Dairy Herd, by S. M. Tracy; Common Ailments of Cows and Calves, and Their Treatment, by A. H. Hartwig; Building Silos, Growing the Corn, and Making Silage, by A. W. Trow; The Physiology of Milk Secretion—With Notes on the Effects of Foods, Drugs, Exposure, Exercise, and Abnormal Bodily Condition, by A. W. Bitting; Management of Dairy Work on the Large Estate of Biltmore Farms, by G. F. Weston; and Dairy Animals of the United States as Reported upon by Twenty State Experiment Stations. A scale of points for scoring dairy animals and a ground plan of a modern creamery are also given.

Creameries in foreign countries (*Spec. [U. S.] Consular Rpts., 24 (1902), pp. IV+162, pls. 10, figs. 3*).—This contains statistics and other information relating to creameries and creamery machinery and products in the principal foreign countries.

Proceedings of the thirteenth annual meeting of the Missouri State Dairy Association, 1902 (*Missouri State Bd. Agr. Mo. Bul.*, 2 (1902), No. 8, pp. 75, figs. 4).—This contains the addresses and discussions. Some of the topics treated were dairying in Missouri, the retail milk business, rations for dairy cows, silos and silage, butter making as a profession, bitter milk, the literature of dairying, and the selection of dairy cows.

VETERINARY SCIENCE AND PRACTICE.

The transference of bovine tuberculosis to man, R. KOCH (*British Med. Jour.*, 1902, No. 2190, pp. 1885-1889).—This is a translation of an address delivered at the International Conference on Tuberculosis in Berlin, October 25, 1902. In this address the author discusses in a critical manner the 2 outbreaks and 28 individual cases of tuberculosis in man which have been mentioned in the literature of the subject as being due to infection from eating meat or milk of tuberculous animals, or to wound infection with tuberculous material of animal origin. In R. Koch's opinion the proof of causal connection between the cases of human tuberculosis and infection from animals is wanting in every case, and while it is not denied that individual cases may arise in man from infection with milk of animal origin, it is argued that such cases must be exceedingly rare, otherwise it is believed that more numerous undoubted cases would be accessible. The author argues that if the meat and milk of tuberculous animals were virulent or generally infectious toward man, numerous outbreaks of extensive character should appear, on account of the fact that the tuberculous milk and meat in any case would naturally be eaten by a number of persons. Such outbreaks, however, have not been observed. In the case originally reported by Ollivier and subsequently quoted at frequent intervals by various writers on the subject, the author calls attention to the fact that Ollivier subsequently admitted his mistake in the original report and stated that the pupils who contracted tuberculosis had not eaten the milk of the cow which was affected with tuberculosis of the udder; the faculty of the institution, however, had eaten this milk and no cases of tuberculosis developed among them.

Are bovine and human tuberculosis identical or not? E. KLEBS and RIEVEL (*Deut. Thierärztl. Wchnschr.*, 10 (1902), No. 3, pp. 21-23).—The authors conclude from their experiments on this question that tubercle bacilli of human origin, after having been artificially cultured a long time, are capable of producing acute typical tuberculosis in calves. The tubercle bacilli of human origin are first exclusively confined to the lymphatic gland in the neighborhood of the point of inoculation; later, however, the tuberculous alterations may extend over the peritoneum and other organs.

Some experiments upon the immunization of cattle against tuberculosis, L. PEARSON and S. H. CHILLILAND (*Philadelphia Med. Jour.*, 10 (1902), No. 22, pp. 842-848, figs. 4).—In this article a summary account is given of experiments during which it was found that the subcutaneous injection of tuberculin has the influence of increasing the resistance of cows to tuberculous lung material given by way of the mouth. The more important literature upon the subject of immunizing cattle against tuberculosis is critically reviewed. This literature includes the publications of E. A. de Schweinitz, J. McFadyean, and E. von Behring.

Experiments with 2 young cattle showed that cattle may be refractory to large quantities of human tubercle bacilli when injected into the blood. One of the 2 animals upon which these experiments were made exhibited considerable resistance to a virulent culture of bovine tubercle bacilli. In March, 1902, a definite test was made of the possibility of immunizing cattle to tuberculosis by repeated intravenous inoculations of human tubercle bacilli not virulent for cattle. In these experiments 4 young cattle were used. They were tested with tuberculin and found to be free from tuberculosis, after which 2 were vaccinated with human tubercle bacilli and

the other 2 were kept as control animals. The vaccinated animals received gradually increasing doses of a suspension of a culture of human tubercle bacilli. In all, 125 cc., representing about 0.16 gm. tubercle bacilli, were administered to each animal. All 4 of the animals were inoculated on July 29 following, by an intratracheal injection of 10 cc. of a suspension of bovine tubercle bacilli known to be virulent for cattle.

All of the animals were killed on different days of the following October and careful post-mortem examinations were made. Both of the control animals were found to be extensively infected with tuberculosis and exhibited fresh tubercles which were evidently in a progressive state. In one of the vaccinated animals it was found that all the organs, with the lymphatic glands and covering membranes, were free from disease, with the single exception of a slight fibrous thickening at the point of vaccination. The second vaccinated animal exhibited 2 hard globular thickenings at the point of inoculation, and within the tracheal mucous membrane 2 minute grayish elevations were found, the smaller one of which contained caseous material. All the other organs were in a healthy condition.

From these experiments it is concluded that by means of repeated intravenous injections of human tubercle bacilli, the resistance of young cattle to virulent bacilli of bovine origin may be greatly increased—to such an extent, in fact, that the animals are not affected by inoculations capable of causing death or extensive infection in cattle which have not been thus protected. Intravenous injections of much larger quantities of human tubercle bacilli than are necessary to confer resistance upon the vaccinated animals may be safely given. The authors have other experiments in progress for the purpose of determining the duration of immunity thus produced and the effectiveness of the method in protecting animals against natural infection.

Is the ingestion of the meat of tuberculous animals dangerous for human beings? V. GALTIER (*Jour. Méd. Vét. et Zootech.*, 5. ser., 6 (1902), Jan., pp. 1-7).—The author discusses the various conditions under which different animals may become infected with tuberculosis. In this discussion especial attention is given to the different degrees of susceptibility to the disease. Brief notes are presented on a number of experiments conducted by the author since 1891 bearing upon the question at issue. The author concludes from his experiments that regulations regarding meat inspection should be modified so as not to require the seizure and destruction of the meat of all tuberculous animals, but only the meat of animals which exhibit pronounced emaciation or extensive tuberculous lesions in the muscles and bones.

On the question of indemnity to butchers for animals found to be tuberculous after slaughter, V. GALTIER (*Jour. Méd. Vét. et Zootech.*, 5. ser., 6 (1902), Mar., pp. 129-143).—The author presents a detailed discussion of this question with especial reference to the French law of July 3, 1895. Many difficulties have been found in attempts to adjust differences arising from the sale of tuberculous cattle to butchers. It is argued that all sales of cattle for butchering should be made subject to the regulations of this law and that legal contests which may arise should be settled in accordance with its provisions.

The history of a tuberculous herd of cows, C. L. BEACH (*Connecticut Storrs Sta. Bul.* 24, pp. 24, figs. 6).—This bulletin contains observations on the station herd of about 50 cows and young cattle. The herd was tested with tuberculin in 1896 and was found to be free from tuberculosis. The test was again applied in 1897, without any reaction. During 1897 a Guernsey cow was bought from a neighboring farmer. The cow did not react to tuberculin test. In the following year, however, this animal suddenly exhibited symptoms of disease. A post-mortem examination showed a case of generalized tuberculosis. The herd was then tested with tuberculin and 12 animals responded, and later 6 other animals responded to the test, making a total of 18. Five of the affected animals were killed and examined; the remainder were

isolated from the healthy animals. The barn was disinfected as thoroughly as possible by means of crude carbolic acid, 1 part in 20 of water. The tuberculin test was applied to the nonreacting herd once or twice a year, and the author believes that it is necessary to test as often as this. During the further course of the experiment 93 animals were tested within 3 years. It was found that no constant differences existed among different breeds with regard to the susceptibility to tuberculosis, since 20 per cent of the Jerseys were affected, 26 per cent of the Guernseys, 21 per cent of the Ayrshires, and 20 of the Holsteins. It was found that the heavy milkers were no more susceptible to tuberculosis than the least productive cows. The evidence obtained from the herd showed that the disease is not inherited, no case of tuberculosis having appeared in 17 calves reared from the tuberculous animals. Repeated injections of tuberculin were found to produce a temporary insusceptibility to the test. Great individual differences in resistance to the progress of the disease were noted in different animals. The author believes that Bang's method of isolation is economical and effective.

Contributions to our knowledge of bovine tuberculosis, J. NELSON (*New Jersey Stat. Rpt. 1901, pp. 352-381*).—Notes are given on autopsies on 2 cows which were affected with tuberculosis. Extensive tables are presented showing the variations in temperature of tuberculous cattle from February to June, and also showing the record of abortions in the college herd. It is stated that the number of abortions is decreasing, but the cause is not well understood. The record of temperatures of tuberculous cattle in the hospital herd fails to indicate that specially favorable conditions for infection are found in the stables where the animals are kept.

The use of eggs as a medium for the cultivation of *Bacillus tuberculosis*, M. DORSET (*Amer. Med., 3 (1902), No. 14, pp. 555, 556*).—During the author's experiments a medium consisting chiefly of hens' eggs prepared in 3 ways so as to include the whole egg content, the yolk of the egg alone, or simply the white alone, was tested. Unusually rapid development of the tubercle bacilli took place on these nutrient media, especially on the whole egg medium. Growth was usually quite apparent by the end of 7 or 8 days, and conspicuous colonies of bacilli were to be observed after a lapse of 10 to 14 days. The egg medium possesses the advantages of causing the rapid growth of the tubercle bacillus and of being easily prepared. It does not cause quite so rapid and abundant growth as secured by Ficker from pure cultures on brain medium.

Treatment of anthrax, MÖBIRS (*Berlin. Thierärztl. Wchnschr., 1902, No. 14, pp. 206, 207*).—The author calls especial attention to a number of cases of anthrax in man which have arisen from carelessness in handling the carcasses of animals dead of anthrax, or from unnecessary inspection or examination of these carcasses. It is recommended that no dissection or other examination of animals dead of anthrax should be made, after diagnosis is fairly certain. This recommendation is made on account of the great danger of becoming infected with anthrax, even when only the most minute skin lesions are to be found on the hands.

Recovery of a cow from anthrax, W. ORTMANN (*Berlin. Thierärztl. Wchnschr., 1902, No. 8, p. 125*).—One animal in a small herd of cattle died of anthrax, and on the next day another cow manifested similar symptoms. In the treatment of this case the author used intravenous injections of colloidal silver, and administered 1 spoonful of lysol in a bottle of water hourly; after 2 days, naphthaline, bicarbonate of soda, and gentian root were administered. Complete recovery took place.

The intravenous application of corrosive sublimate, SCHMIDT (*Berlin. Thierärztl. Wchnschr., 1902, No. 12, pp. 181-184*).—The author conducted a number of experiments, for the most part on small experimental animals, which were infected with anthrax and fowl cholera. As the result of these experiments it was found that the injections of corrosive sublimate did not produce any general reaction of the

experimental animal, except when very large doses were used. The pulse, temperature, and respiration remained unchanged. Solutions as strong as 0.5 per cent may produce local irritation; it is recommended, therefore, that this drug be used in very dilute solutions. The condition known as mercurialism may appear after injections of corrosive sublimate. The best place for making the injection is considered to be the jugular vein. Animals which received 5 injections inside of 14 days did not exhibit any alteration in the tuberculous processes with which they were affected.

A fatal case of induced Texas fever, C. F. DAWSON (*Amer. Vet. Rev.*, 26 (1902), No. 2, pp. 124-126).—A detailed description is given of a fatal case of Texas fever in an immune Southern animal. The acute and finally fatal symptoms were apparently brought about in consequence of a shock received by the operation of dehorning. Two other steers dehorned at the same time appeared to be slightly affected in the same way, but recovered, while yearlings did not develop any symptoms of the disease. These cases are believed to add another reason to those which already exist for performing the operation of dehorning at an early age.

Observations on Bacelli's method of treating malignant foot-and-mouth disease, KOSKE (*Berlin. Thierärztl. Wehnschr.*, 1902, No. 10, pp. 145-150).—A critical review of the extensive literature on this subject is presented by the author. The large number of experiments conducted by various authors are brought together in a tabular form for the purpose of showing the conditions and results of these experiments. The author concludes from the results of the experiments of others, as well as from his own observations, that, when all conditions surrounding the reported cases of foot-and-mouth disease treated by this method are considered, no influence can be ascribed to the injection of corrosive sublimate. This drug, when injected intravenously, did not prevent an outbreak of the disease, or an unfavorable course in cases which were treated by the author.

The treatment of foot-and-mouth disease, WEINSHMEIER (*Deut. Thierärztl. Wehnschr.*, 10 (1902), No. 16, pp. 153-155).—In outbreaks of this disease the author believes that the most important operations are immediate removal of affected animals, and nutritious dieting of animals which have been exposed. For the purpose of preventing the disease it is urged that susceptible animals be rendered as resistant as possible by keeping them in a healthy and well nourished condition, and that the virus of foot-and-mouth disease be kept attenuated or be destroyed by abundance of fresh air and direct sunlight.

Bovine eczema, C. BRÉGEARD (*Jour. Méd. Vét. et Zootech.*, 5. ser., 6 (1902), Feb., pp. 95, 96).—A brief note on the treatment of this disease with a solution of nitric acid in water in a proportion of 1 to 10. The remedy was frequently applied to the affected parts and the results were very satisfactory.

Abortion in cows, P. MALCOLM (*Amer. Vet. Rev.*, 26 (1902), No. 2, pp. 127-130).—The usual factors and conditions which are important in bringing about cases of abortion are enumerated. In case of abortion the author recommends burning or otherwise destroying the fetus and fetal membranes, and disinfection of the stable. It is not believed that the treatment with antiseptic washes as usually applied to cows is of any value in preventing the development of this disease.

Infectious pneumonia of calves, H. MARDER (*Berlin. Thierärztl. Wehnschr.*, 1902, No. 7, p. 110).—It is reported that this disease has been observed in calves in the form of a plague on several occasions. The disease seems to break out in summer as well as in winter. Medicinal treatment was in all cases without good result. It is recommended that all healthy animals be immediately isolated from the diseased and suspected ones, that the stables in which the diseased calves have been confined be torn down and used for fire wood, and that the superficial layer of the soil around and underneath such stables be removed and the surface treated with chlorid of lime or a similar disinfectant.

Treatment of sheep scab, NAGEL (*Deut. Thierärztl. Wehnschr.*, 10 (1902), No. 1, pp. 3-5).—A number of experiments were conducted for the purpose of testing the

value of a creolin dip in the treatment of sheep scab. The author calls attention to the necessity of careful local treatment of the affected parts, to maintaining proper temperature of the dip, and to proper treatment of the sheep between the first and second dipping. It was found not to be necessary to rub affected parts of the skin with carbolyzed soap before dipping. After dipping, however, it is believed to be desirable that the scab areas be vigorously rubbed with a brush in order to bring the creolin in contact with all the scab mites. The author found a 2.5 per cent creolin dip to be a thoroughly reliable dip for destroying scab mites.

Experiments with Bacillol sheep dips, K. KASSELMANN (*Deut. Thierärztl. Wchnschr.*, 10 (1902), No. 13, pp. 121, 122).—The author tested this dip on 1,200 sheep, and obtained results which indicate that it is quite as effective as creolin, or perhaps somewhat better. No symptoms of poisoning were observed in sheep after being dipped in Bacillol. This remedy is therefore considered a valuable sheep dip of harmless nature, and it is stated that it can be obtained conveniently for a reasonable price.

The Landsberger Swine Erysipelas Serum, B. SCHUBERT (*Berlin. Thierärztl. Wchnschr.*, 1902, No. 19, pp. 289-293).—Extensive experiments were conducted, during which the effect of Süsserin, Lorenz Serum, and Landsberger Serum were compared. These experiments were conducted in various cities of the German Empire and under various conditions. From the consideration of the literature of the subject and the author's own observations, it is concluded that a mixture of several active immune sera is of distinct advantage in producing immunity. The Landsberger Swine Erysipelas Serum differs from all previously known swine erysipelas sera; it is a multivalent serum, i. e., a mixture of immune sera obtained from different species of animals. This composition gives the Landsberger Serum an advantage, and even in small doses it exercises a more rapid and powerful action than any simple serum.

Results of vaccination with Septicidin for swine plague and hog cholera in the year 1901, SCHREIBER (*Berlin. Thierärztl. Wchnschr.*, 1902, No. 8, pp. 121, 122).—Reports received for the year 1901 regarding vaccination experiments with this substance show that 6,224 animals were vaccinated. Of this number, 2,943 were inoculated for purposes of protection. Of the animals already affected, 64.02 per cent were cured by vaccination. Vaccination experiments were conducted upon a herd of hogs in which, at the time of vaccination, the rate of mortality was 53.42 per cent. After vaccination, the death rate fell to from 3 to 5 per cent.

A report of vaccination in the year 1901 with the vaccine from the Swine Erysipelas Institute at Prenslau, HELFERS (*Berlin. Thierärztl. Wchnschr.*, 1902, No. 15, p. 233).—It is stated that the Swine Erysipelas Institute at Prenslau distributed 500,000 doses of vaccine during the year 1901. Reports have been received covering the results from 163,068 animals vaccinated. Of this number, 157 became infected with swine erysipelas and 87 died. The number of deaths from swine erysipelas in consequence of vaccination was 0.019 per cent, and the number of deaths from the same disease in spite of vaccination was 0.033 per cent.

Report on the vaccinations made in the Province of Saxony in the year 1901-2 with the Lorenz vaccine, H. RAEBIGER (*Berlin. Thierärztl. Wchnschr.*, 1902, No. 20, p. 301).—The number of hogs vaccinated during the year in the Province of Saxony with Lorenz vaccine amounted to 70,000. In 1900 the number was 24,000. It is stated that the results obtained from the use of this vaccine have been so satisfactory that the Institute has undertaken to guarantee indemnity for any loss which may be incurred in consequence of the use of the Lorenz vaccine. The percentage of recovery when the vaccine is used for therapeutic purposes is stated to be between 70 and 75 per cent.

The necessity and the method of observing a uniform technical procedure in trichina inspection, WEBER (*Deut. Thierärztl. Wchnschr.*, 10 (1902), No. 2, pp. 13-16).—The author presents arguments showing the necessity of careful prac-

tice of inspection for trichina. It is argued that the method of making this inspection should be uniform instead of uncertain and defective, as it is at present in many governmental districts. Attention is called to the necessity of special training, careful examination, and supervision of the trichina inspectors.

The transmission of glanders, and danger of accidental inoculation to which human beings are subjected, V. GALTIER (*Jour. Méd. Vét. et Zootech.*, 5. ser., 6 (1902), Apr., pp. 197-210).—Detailed notes are given on the usual means by which glanders is communicated from one animal to another, under natural conditions. The various forms of glanders are discussed. A large number of experiments were made in placing glanderous material upon the uninjured conjunctiva of guinea pigs. During these experiments it was found that a perfectly healthy and intact conjunctiva could absorb the virus of glanders. The more bacilli present in the virus used in these experiments, the more certain was the infection. It was found that by washing the eye after contaminating the conjunctiva the infection could be prevented. No antiseptics need be used for this purpose, since water appeared to serve equally well to prevent the entrance of the glanderous bacilli into the eye. The application of these results to accidental contamination of the human eye with glanderous material is apparent. If the virus of glanders is thrown into the eye by the violent sneezing or coughing of glanderous horses, the careful washing of the eye will prevent the contraction of glanders.

Treatment of azoturia with potassium iodid, T. S. CHILDS (*Amer. Vet. Rev.*, 26 (1902), No. 3, pp. 219-223).—Good results are reported from the use of potassium iodid in the treatment of a number of cases of azoturia. This chemical was injected into the bladder in doses of $\frac{1}{2}$ oz. or more in $\frac{1}{2}$ pt. of water. The dose may be repeated if necessary. The favorable action of the drug was usually observable within a short time, and complete recovery in nearly all cases took place after from 3 to 6 days. The author states that several other veterinarians have used this method of treatment with varying results. Some of them had entirely negative results, potassium iodid apparently exercising no beneficial action whatever; in other cases good results were obtained. The discrepancy in the results of different veterinarians appears difficult of explanation. It is suggested that the disease may vary somewhat in virulence or otherwise in different climates.

Surra, J. J. VASSAL (*Rev. Agr. Réunion*, 8 (1902), No. 5, pp. 220-225).—The symptoms, pathological anatomy, and etiology of this disease are briefly discussed and compared with those of other closely related diseases. Notes are also given on the animals which are subject to the disease. These include monkeys, horses, donkeys, mules, goats, sheep, cattle, buffaloes, camels, elephants, dogs, cats, rabbits, guinea pigs, and rats.

The tsetse fly disease, A. PROOST (*Rev. Gén. Agron. [Louvain]*, 11 (1902), No. 5, pp. 266, 267).—This disease is compared with surra. Brief notes are given on the habits of *Tabanus tropicus*, which carries the parasite of surra, and *Glossina morsitans*, which is the insect agent in the transmission of Nagana.

South African horse disease, RICKMANN (*Berlin. Thierärztl. Wchnschr.*, 1902, No. 1, pp. 4, 5).—The literature of this subject is briefly discussed by the author. It is believed that the spread of this disease depends strictly upon the agency of insects in carrying the blood parasites, and that the insects thus concerned can not become infected without previously sucking the blood from a diseased horse.

Critical notes on the treatment of colic in horses, WITT (*Berlin. Thierärztl. Wchnschr.*, 1902, No. 4, pp. 61-63).—More than 1,000 cases of colic were treated by the author by means of barium chlorid, which was injected into the jugular vein in doses of from $\frac{1}{2}$ gm. to 3 gm. Some horses appear to be particularly susceptible to the action of this drug, and with these it must be given in small doses. In the majority of cases the author reports better results from the use of barium chlorid than from any other treatment for this disease.

The pathology and differential diagnosis of infectious diseases of animals,

V. A. MOORE (*Ithaca: Taylor & Carpenter, 1902, pp. XIV + 380, pls. 8, figs. 73*).—The present volume contains a general account of etiology and infection in connection with the more important infectious diseases of animals. Special chapters are devoted to the following subjects: Diseases caused by Streptococci; diseases caused by organisms of the genus Bacterium; diseases caused by bacilli; diseases caused by higher fungi; diseases caused by Protozoa; infectious diseases of unknown cause, and a few diseases caused by animal parasites. Brief notes are also given on the approved methods of disinfecting stables and premises after outbreaks of infectious diseases.

AGRICULTURAL ENGINEERING.

The scope and purpose of the irrigation investigations of the Office of Experiment Stations, E. MEAD (*U. S. Dept. Agr., Office of Experiment Stations Rpt. 1901, pp. 417-436, pls. 4*).—A brief discussion of the work of the Office in relation to irrigation in the arid and humid regions and the insular possessions of the United States, with an explanation of the need of reform in irrigation laws and a list of all the publications of the Office on irrigation.

Operations at river stations, 1901 (*Water Supply and Irrig. Papers, U. S. Geol. Survey, Nos. 65, pp. 334; 66, pp. 188*).—Tabulated daily and monthly discharge during 1901 of a large number of streams are reported. The material is divided into two parts, the first relating to the eastern portion of the country and the second to the western. The first includes measurements of 10 streams in Maine and 8 streams in other parts of New England, streams in the St. Lawrence River drainage basin, Upper Hudson River drainage, Lower Hudson River and Long Island Sound drainage, Lake Ontario drainage, Mohawk River drainage, Middle Atlantic Coast drainage, Southern Atlantic Coast drainage, Eastern Gulf drainage, Eastern Mississippi River drainage, and Great Lakes drainage. The second includes measurements of the Hudson Bay drainage, Upper Missouri River drainage, Platte River drainage, Kansas River drainage, Arkansas River drainage, Western Gulf drainage, Colorado River drainage, Interior Basin drainage, Columbia River drainage, Northern Pacific Coast drainage, San Francisco Bay drainage, and Southern California drainage.

Pumping water for irrigation (*Forestry and Irrig., 8 (1902), Nos. 1, pp. 43, 44, figs. 2; 2, pp. 83-86, figs. 3; 3, pp. 130-133, figs. 4; No. 4, pp. 176, 178, figs. 2*).

Municipal engineering and sanitation, M. N. BAKER (*New York and London: The Macmillan Co., 1902, pp. VIII+317*).—The author states that this book "is designed to be a review of the whole field of municipal engineering and sanitation, rather than an exhaustive study of one or a few branches of the subject. The most vital points, however, under each class of activities and interests have been dwelt upon, the underlying principles stated, and, in many instances, details from actual practice given." It treats of ways and means of communication; municipal supplies; collection and disposal of wastes; protection of life, health, and property; and administration, finance, and public policy.

Cane cutting machinery in Australia (*Hawaiian Planters' Mo., 21 (1902), No. 4, pp. 174, 175*).—Preliminary trials of a mechanical device for cutting cane invented by Herbert Paul are briefly reported.

Oil for roads, O. W. LONGDON (*Hawaiian Planters' Mo., 21 (1902), No. 5, pp. 214-217*).—A brief account of the use of crude petroleum in road making at Los Angeles, Cal.

MISCELLANEOUS.

Annual Report of the Office of Experiment Stations, 1901 (*U. S. Dept. Agr., Office of Experiment Stations Rpt. 1901, pp. 489, pls. 41*).—This contains a report on the work and expenditures of the agricultural experiment stations in the United States for the fiscal year ended June 30, 1901, including brief abstracts of all station

publications received and statistics relative to organization, expenditures, etc.; reports of the experiment stations in Alaska, Hawaii, and Porto Rico, noted elsewhere; and a review of the irrigation and nutrition investigations of this Office, also noted elsewhere.

Fifteenth Annual Report of Kansas Station, 1902 (*Kansas Sta. Rpt. 1902*, pp. XXXIII+251-255).—This contains the organization list of the station; a financial statement for the fiscal year ended June 30, 1902; a list of station publications; a review of the work of the different departments during the year; an account of the establishment of the Fort Hays branch station, with a statement of the lines of work in progress; text of the State law relating to the destruction of gophers and prairie dogs, with notes on the work done along this line; and an account of cooperative experiments in range improvements.

Fifteenth Annual Report of Mississippi Station, 1902 (*Mississippi Sta. Rpt. 1902*, pp. 35).—This contains the organization list of the station, a financial statement for the fiscal year ended June 30, 1902, and reports of the director and heads of departments. Reprints of bulletins 69-77 of the station on the following subjects are appended: Texas fever (E. S. R., 13, p. 995); records of station cows, feeding dairy cows (E. S. R., 13, p. 984); milk fever (E. S. R., 13, p. 995); anthrax (E. S. R., 13, p. 994); tick fever or murrain in Southern cattle (E. S. R., 14, p. 397); some mosquitoes of Mississippi and how to deal with them (E. S. R., 14, p. 375); strawberry culture in Mississippi (E. S. R., 14, p. 356); beef cattle (E. S. R., 14, p. 483); and analyses of commercial fertilizers (E. S. R., 14, p. 558).

Annual Report of New Jersey Stations, 1901 (*New Jersey Stas. Rpt. 1901*, pp. XI+587).—This includes the organization lists of the stations, a financial statement of the State Station for the year ended October 31, 1901, and of the College Station for the fiscal year ended June 30, 1901; a report of the director reviewing the different lines of station work; and reports of the chemists, assistant in soil chemistry and bacteriology, assistant in horticulture, assistant in dairy husbandry, biologist, botanist, and entomologist noted elsewhere.

Sixth report of extension work, J. CRAIG (*New York Cornell Sta. Bul. 206*, pp. 125-156, figs. 10).—This report covers the period from January, 1900, to July, 1902, and is in continuation of the report published as Bulletin 159 of the station (E. S. R., 10, p. 1098). It deals with the work of instruction and investigation carried on by the college of agriculture and the experiment station under the provisions of the State law relating to the promotion of agricultural knowledge. Special reports by those cooperating in the work are included as follows: The Nature Study Movement, by L. H. Bailey; Junior Naturalists—the Work with the Children, by J. W. Spencer; Lectures in Nature Study, by Anna B. Comstock; Home Nature Study Course, by Mary R. Miller; Cooperative Experiments in General Agriculture, by J. L. Stone; Work of the Entomological Division, by M. V. Slingerland; and Dairying and Animal Industry, by H. H. Wing.

A review of the foreign literature relating to agriculture, soil management, and plant culture for the year 1900, T. WESTERMANN (*Separate from Tidsskr. Landbr. Planteavl, 8 (1902), pp. 147*).—References, extracts, and summaries are given of a large amount of the literature relating to the topics indicated in the title. The titles are arranged alphabetically by authors under the different chapters, the principal ones being air and soil, soil improvement and management, chemical composition, nutrition, and improvement of agricultural plants, plant culture arranged by crops, agricultural education, experiment stations, etc.

Yearbook of the natural sciences, 1901-02, M. WILDERMANN (*Jahrb. Naturw., 17 (1901-2), pp. 533, figs. 52*).—This volume contains brief abstracts of the more important literature published during the past year on physics, chemistry, applied mechanics, meteorology, physical geography, astronomy, mathematical geography, zoology, botany, forestry, agriculture, mineralogy, geology, anthropology, ethnology, sanitation, medicine, physiology, and industrial technology.

NOTES.

ALASKA STATION.—C. C. Georgeson, director, is spending a few weeks in Washington. R. W. De Armond, a graduate of the Kansas Agricultural College and recently a student assistant in horticulture, has been appointed horticulturist, and will be located at Sitka. His appointment will take place April 1. It is planned to make Sitka more especially a horticultural station for experiments with fruit and the propagation of plants for distribution. Ten varieties of apples thought to be specially promising for that locality have been set out, and experiments will be made in grafting on the native crab as a stock. Work will also be carried on in the improvement of the native fruits, especially the cranberries, raspberries, and strawberries.

CALIFORNIA UNIVERSITY.—J. M. Wilson, assistant professor on irrigation, and in charge of the Pacific Coast division of the irrigation work of this office, died January 27, after an illness of several months.

IDAHO UNIVERSITY AND STATION.—Lowell B. Judson, a graduate of Harvard and for two years a special student in horticulture at the Michigan Agricultural College, has been appointed horticulturist of the university and station.

ILLINOIS UNIVERSITY AND STATION.—Hugh E. Ward, chief assistant in soil bacteriology, died of heart disease December 29. He had been granted a year's leave of absence for study in Europe, but after spending a few weeks at Zurich he was compelled by failing health to return home, where he died ten days after his arrival.

MARYLAND STATION.—T. M. Price, assistant chemist of the station, has resigned to accept a position as scientific assistant in the Bureau of Animal Industry.

MISSOURI FRUIT STATION.—J. T. Stinson, director, has resigned to accept the position of superintendent of pomology in the department of horticulture of the Louisiana Purchase Exposition.

OKLAHOMA COLLEGE AND STATION.—J. S. Malone, assistant in animal husbandry, has resigned and accepted a position as manager of a 2,500-acre farm in the vicinity of Oswego, Kans. There are 22 students in the short course in agriculture, horticulture, and mechanic arts, and 20 in the short course in domestic economy. Several were turned away for lack of space.

TENNESSEE STATION.—Andrew M. Soule, agriculturist and vice-director of the station, has been elected director. Some important digestion experiments have been undertaken by the chemical department.

WYOMING STATION.—The completion and occupation of the new Science Hall has enabled the board of trustees to grant more room in the main university building for the station headquarters. The south end of the building (main floor) has been assigned to the director and agriculturist with his assistants. This furnishes office rooms and additional laboratory space, and the library of the experiment station and agricultural department is shelved where it will be more accessible and convenient.

CONCENTRATION SCHOOLS IN CANADA.—Through the munificence of Sir William Macdonald, of Montreal, the experiment of consolidated schools, in which the principles of agriculture will be taught, is to be tried in each of the five eastern provinces of Canada. The details of this experiment are in the hands of Prof. James W. Robertson, of Ottawa. The plan is to unite the rural schools in a district and to convey the children to a central school. For the present, one school is planned for each of the eastern provinces. In these central schools, besides the usual subjects of the

8 grades and possibly the high school, domestic economy, manual training, and nature study will be taught. Under the direction of Professor Robertson eleven Canadian teachers have been sent to this country for a 6 months' course in science and agriculture, after which they will go to the agricultural college at Guelph for a further course of 2 months. Five of these men will then act as principals of the 5 consolidated schools and teach the nature study. In addition to these schools, there is to be a traveling inspector in nature study in each province, who will visit a group of 5 of the ordinary schools of the province, which are separate and apart from the consolidated schools but which are regarded as prospective centers for consolidated schools. Each of these 5 schools will be visited once a week and instruction given in school garden work and nature study. The consolidated schools and the schools visited by the traveling inspectors will each be provided with school gardens. It is proposed to begin work on this plan next September with the opening of the school year. Sir William Macdonald bears the expense for 3 years, over and above what the same schools are now costing, and the whole work will be carried out under the regularly appointed educational authorities.

RURAL EDUCATION IN FRANCE.—In a paper on French rural education, read before the Society of Arts, and reported in *Nature*, Cloudesley Brereton explained the part taken by the primary and secondary schools in the agricultural education of the nation. In France in some communes one person in every four is a land proprietor, and the aim in the primary schools has been to give the pupils some grasp of the principles underlying the science of agriculture. The teacher is not expected to follow rigidly the departmental programme, but to choose those portions which best suit the particular district. The teachers in these schools are trained by professors of agriculture in the training colleges. There is still some doubt among French authorities on education whether the scientific or the agricultural side of the instruction should predominate in primary schools. In the secondary schools of France agricultural education has an insignificant place, although the work done by means of lectures and evening classes conducted in connection with clubs and other organizations is important.

PROPAGANDA FOR THE RATIONAL USE OF FERTILIZERS IN ITALY.—A voluminous report has been received on this work, which is carried on by a section of the Italian Federation of Agricultural Societies. This federation was organized in 1892, but the section on fertilizers was not formed until 1898. The objects of the propaganda are to encourage the establishment of experimental and demonstration fields to test fertilizers, to disseminate information relating to fertilizers by means of publications of various kinds, to answer inquiries relating to fertilizers, and to hold public meetings to discuss the subject. The report is the first which has been issued on the propaganda, and covers the period from 1898 to 1901, inclusive. The results of a large number of cooperative experiments on a great variety of crops in different parts of Italy during the last 4 years are reported in detail, and their practical value and application are discussed, with instructions for carrying on such experiments.

INTERNATIONAL DAIRY CONGRESS.—The Société Nationale de Laiterie of Belgium has requested the holding of an international dairy congress at Brussels in September, 1903, immediately after the eleventh congress of hygiene and demography. The questions proposed for the consideration of the congress are the suppression of fraud in the dairy industry, the hygiene of milk and its products, and the creation of an international dairy association. Opinions relating to the movement are requested, communications to be addressed to Arm. Collard Bovy, general secretary of the Société Nationale de Laiterie, Square Marie-Louise, 56, Brussels.

ELECTRICITY AND RAIN MAKING.—The following item comes somewhat round about, being copied from an English newspaper by the *Agricultural Journal and Mining Record*, of Natal. The item states that some interesting experiments for the

artificial production of rain by means of electricity have just been carried out in Japan. Waves of electricity directed skyward under a system somewhat similar to that upon which wireless telegraphy is based have resulted in atmospheric disturbances of far greater area than any ever artificially produced through the medium of detonating explosives in the upper air strata. The probability of achieving greater success in rain making through the means of electricity than by the use of explosives has been urged by scientists for several years. This attempt by the Japanese, however, is the first practical effort to prove the truth of the theory. It was attended by conspicuous success. Operations were commenced at 11 in the evening, but there was no sign of atmospheric change until 9 o'clock next morning, when a cluster of clouds was observed over the hill on which the experiment was held. At length rain began to fall, followed by a second fall at 11 a. m., and afterwards a third, fourth, and fifth, the last being about 9.30 in the evening. The area upon which the rain fell extended over many miles.

THE NILE DAM AT ASSUAN.—The great irrigation dam at Assuan was opened with much ceremony in December last. This dam, the largest of its kind ever constructed, will, according to *Nature*, hold up the waters of the Nile for a distance of 147 miles. It is a mile and a quarter long, constructed of solid granite and cement upon a natural bed of granite, over which the river flows. It is 82 ft. high, 80 ft. thick at the base, and 24 ft. at the top. There are 140 lower openings, 23½ ft. high by 6 ft. wide, and 40 upper openings, provided with doors so hung and balanced that they can be raised and lowered with little labor. Through these openings the Nile water will flow in time of flood, carrying with it the sediment that may have accumulated when the gates were closed. As the flood waters diminish the gates will be closed and the water impounded, to be taken out in such quantities as are required for irrigation during the summer months. For the accommodation of navigation a canal 50 ft. wide and 1 mile long has been cut through the rocks, and a lock constructed for a descent of 59 ft. in four drops. For the further regulation of the water another dam has been constructed 330 miles down the river to control the irrigation below that point. The most perfectly irrigated lands in Egypt command a rental equal to about \$25 an acre, while the imperfectly irrigated land is not worth more than \$5 an acre. About one-third of Egypt, or some two million acres, is yet undeveloped. It is estimated that the rental value will be increased nearly \$30,000,000 a year by an effective system of irrigation.

NECROLOGY.—A. Millardet, who occupied the chair of botany in the faculty of science in the University of Bordeaux for 25 years, died early in December, 1902. Upon his arrival at Bordeaux from the University of Naney, the vineyards of Bordeaux were suffering from the ravages of phylloxera, and he at once began the investigation of that pest, studying its life history and means for preventing injury. It is claimed that he was the first to point out the resistance of American grapes to phylloxera and to suggest their use as stock upon which to graft the European varieties. During this investigation he became interested in the fungus diseases of the grape, particularly the downy mildew, black rot, and anthracnose, and accidentally discovered the value of copper salts in preventing the development of the fungi. In collaboration with U. Gayon he discovered the value of the fungicide now known everywhere as Bordeaux mixture. To M. Millardet is due the credit for the first systematic trial of this fungicide in well-planned experiments, the results of which were published in 1885. M. Millardet retired from active work in the University of Bordeaux during the past year, and had been devoting himself to the reestablishment of vineyards in the calcareous soils of Saintonge, near Bordeaux.

Antoine Ronna, the eminent engineer, died at Paris November 25, 1902. He was born in London, December 9, 1830, his father being an Italian refugee, his mother the daughter of an English clergyman. He was educated in Italy and France, and at different times during his life held important scientific and official positions in

England, France, and Austria. He was an accomplished linguist and his knowledge of languages was of great service to him in the prosecution of his scientific studies and inquiries. He made valuable contributions to agricultural science, his first published work of importance in this respect being a study of the manufacture and use of phosphate of lime in England, which appeared in 1864. His reputation, however, rests mainly on his contributions to irrigation and sewage disposal as embodied in his exhaustive treatises on these subjects (1874 and 1888-89). He was also the author of important publications on agricultural industries (1869), the agricultural investigations of Rothamsted (1877) and Woburn (1886-1888), the wheat industry in the United States (1880), and numerous smaller articles on agricultural subjects.

The death is announced of N. Sibirtzev, one of the foremost of the soil investigators in Russia and professor of "pedology" or the science of soils in the Agricultural and Forestry Institute of Novo-Alexandria. He was the most prominent pupil and collaborator of Prof. V. V. Dokouchayev, who organized the soil work in Russia and founded a new school of soil investigation. Professor Sibirtzev's most notable contribution to the subject was a genetic or natural classification of soils, which, in the study of soil formations, differentiates between the parent rock species and the cultivated horizon. An account of Sibirtzev's soil investigations and his classification, taken from his memoirs, appeared in volume 12 of this journal.

Dr. G. Thoms, professor of agricultural chemistry at the Polytechnic Institute of Riga and director of the experiment station at that place, died November 2, 1902, at the age of sixty years. Professor Thoms was made director of the Riga station, the oldest station in Russia, in 1877. He reorganized and developed the station and under his direction it became an important factor in the development of the agriculture of the Baltic region. One of his chief lines of work was his extensive soil investigations and these led him to studies in plant nutrition and the use of fertilizers on a practical scale. He was very active and energetic and enjoyed the confidence of progressive agriculturists and managers of estates to an unusual degree. Professor Thoms visited this country on two different occasions. In 1868, with several other chemists, he established a factory for making beef extract in western Texas. The factory was subsequently burned and the enterprise abandoned. In 1893 Professor Thoms returned to America and visited a number of our agricultural institutions. He was a great admirer of America, and had followed the work of our agricultural experiment stations unusually closely.

MISCELLANEOUS.—At the recent meeting of the Society for the Promotion of Agricultural Science, William Frear was elected president and F. M. Webster secretary-treasurer for the succeeding year.

The officers elected by the Association of Economic Entomologists are as follows: President, M. V. Slingerland; first vice-president, C. M. Weed; second vice-president, H. Skinner; secretary and treasurer, A. F. Burgess.

During the International Live Stock Exposition in Chicago a life-size oil painting of Prof. W. A. Henry was hung in the so-called Hall of Fame in the new Live Stock Record Building. The portrait is an excellent likeness of Professor Henry, and is a present from the many students who have profited by his teachings in Wisconsin. It is the first contribution to a proposed gallery of men conspicuous for their labors in behalf of the live-stock industry in the United States.

The announcement has been received of the Columbia School of Poultry Culture at Waterville, N. Y. This is a correspondence school carried on under the direction of Dr. A. A. Brigham, formerly of the Rhode Island College and Station, assisted by 4 other experts in poultry. The course of instruction is planned to cover a year and includes plans for poultry buildings and practical advice.

EXPERIMENT STATION RECORD.

VOL. XIV.

MARCH, 1903.

No. 7.

The first report of the bureau of agriculture of the Philippine Islands, by Prof. F. Lamson-Scribner, has just been published as a part of the report of the United States Philippine Commission. Although it represents only five or six months' service in the islands, it shows that good progress has been made in organizing the new bureau, laying out its work, and getting into contact with the more enlightened class of its constituents. Besides the chief of the bureau, the staff includes a botanist and assistant agrostologist; experts in soils, tropical agriculture, plant culture and breeding, and farm management; a superintendent of the San Ramón farm, a chief clerk, a translator, an artist, and clerical assistants. A fiber expert was appointed and served for a time, but has since resigned, and an expert in animal industry is contemplated.

The experiment stations and farms established or projected under the Spanish Government have been visited by representatives of the bureau, to determine their condition and suitability for experimental work. "In general it was found that buildings, where any had ever existed, had been destroyed or had greatly deteriorated, and that farm machinery, tools, etc., had been stolen or scattered or had become useless through neglect. In some instances tracts of land selected by the Spanish Government were found to be well suited for the purposes for which they were intended, while in other cases they were so badly situated as to suggest the advisability of their final abandonment."

Work has been carried on during the season at one of these farms located at San Ramón, in the district of Zamboanga, island of Mindanao. The cocoanut groves and abacá fields, as well as the farm generally, were found in a deplorable condition, due to the long period of neglect. The cultivated area has been put in excellent condition. There are now nearly nine thousand cocoanut trees on the place, some six hundred of which are in bearing, and thirty thousand plants of Manila hemp were set out during the season. The farm has over a thousand cacao trees, but these were stung during the season by an insect which destroys the beans. Although at present rather isolated, it is thought that the San Ramón farm offers unusually good opportunities for demonstrating the income-producing power of the lands of the islands by the growth of staple crops.

Field work has been undertaken in Batangas Province, at the request and with the cooperation of General Bell, the object being to demonstrate the practicability of using American machinery, and the growing of forage plants and certain staple crops, such as cotton, tobacco, sugar cane, etc., according to American methods. At Baguio, on the island of Mindoro, experiments were made in the cultivation of American vegetables and forage crops, and the location studied with reference to the establishment of an experiment station for the growing of extra-tropical crops and the possible site of a botanical garden. This locality is thought to offer unexcelled advantages for experimental work with plants, the climate admitting of the growing of a great variety of tropical, subtropical, and temperate-zone plants.

The improvement of the native and cultivated plants of the islands and the introduction of new kinds or varieties quite naturally suggested itself as a profitable line of work. The bureau distributed over 18,000 packages of seeds, representing a great variety of field and garden crops, to a selected list of 730 individuals to test their adaptability, and is collecting seeds of the economic plants of the islands for experimental cultivation with a view to improvement. A new species of wild grape has been discovered in the island of Negros, which it is thought may prove of great value for the ultimate development of a race of grapes adapted to the region. The islands have heretofore produced no grapes, except a very limited quantity grown in the city of Cebu.

With the exception of the mango the fruits of the region have been practically wholly neglected in the past. Such tropical fruits as bananas and pineapples and the extra-tropical citrus fruits, are wholly undeveloped in the islands, although the conditions of the soil and climate are generally adapted to the growth of bananas and pineapples, and, in selected localities, to oranges and other citrus fruits. "Improved varieties of orange and lemon brought from California are flourishing both in the lowlands and in the mountains of Benguet, while pear, peach, apricot, and plum trees have been successfully introduced in the latter region."

An experiment station for the growing of rice upon a large scale will be established near the center of the great rice-producing area, extending from Manila to Dagupan.

The fiber industry of the islands has received considerable attention, and in addition to a report upon the fiber investigations, a preliminary survey is noted of the soils of the principal region supplying Manila hemp.

One of the greatest drawbacks to agriculture in the islands at present is the lack of draft animals. Rinderpest has been very prevalent and destructive among the carabaos, or water buffaloes, which are the main reliance for farm work, and glanders and surra have caused serious

losses among horses. As a result, farm work has been entirely abandoned in some sections. The Commission has made an appropriation for an extensive stock farm, to be used in the introduction and breeding of draft and dairy animals, and has authorized the use of government funds for the importation of draft animals to be sold on easy terms in the provinces where they are most urgently needed. The success of these efforts to restock the islands is dependent upon the ability of the serum institute to turn out a satisfactory antirinderpestic serum in sufficient quantities.

Some of the agricultural opportunities in the Philippines are pointed out by Dean C. Worcester, secretary of the interior, whose department includes the bureau of agriculture. "But a small part of the soil capable of producing these crops to advantage is at present under cultivation. The methods of extracting sugar now used leave approximately 50 per cent of the sugar in the pressed cane when it is thrown on the dump pile. Hemp is cultivated in a haphazard way, where it is not allowed to grow practically wild, and the fiber is extracted by hand. No systematic and sustained effort has ever been made to improve the quality of Philippine tobacco, and the methods used in curing it are very primitive. If rich returns have been realized from the growing of these commodities in the past upon a comparatively limited scale, the results of extensive cultivation with modern methods and machinery are too evident to require discussion. . . .

"There are very large areas of government lands admirably adapted to the cultivation of cocoanuts. Coconut trees come to bearing in from five to seven years, reaching the bearing stage more slowly as the altitude increases. The trees can be grown readily and with comparatively little danger of loss. Under existing conditions the minimum annual profit from a fairly good bearing tree is \$1 Mexican, and frequently two or three times this amount is realized. The ground under the trees is now either allowed to grow up with brush or is kept clear by hand. The growth of underbrush injures the soil and leads to the loss of falling nuts, while clearing by hand is quite expensive. The use of mowing machines would result in a great saving in the cost of labor necessary to keep the ground clear and gather the nuts. Other crops, such as Indian corn and alfalfa, can be grown between the rows of coconut trees while the latter are maturing, and used to fatten hogs, which always bring a good price in the Philippine market."

There are good opportunities for developing cacao and vanilla growing in numerous regions, there being at present no true cacao plantation in the archipelago and the methods practiced very primitive and wasteful.

"An especially fine coffee is grown in the mountain regions of Benguet and Bontoc and in the province of Lepanto. The bushes

yield heavy crops and the unhulled coffee at present sells readily in Manila at \$35 Mexican per cavan [3.47 cu. ft.], for consumption in these islands or for shipment to Spain. Coffee bushes come to bearing in Benguet in three years. There is no region in the United States which has a more healthful or delightful climate than is afforded by the Benguet highlands, where a white man can perform heavy field labor without excessive fatigue or injury to his health."

The production of milk and of beef are thought to offer great opportunities for profitable development, provided animal diseases can be kept within bounds.

The primitive and undeveloped condition of agriculture in this region, much of which is naturally so productive, indicates the splendid field which lies before the bureau of agriculture for experimental and demonstration work. The country is essentially an agricultural one, and the greatest opportunities for development lie in that direction. The problem of bringing about this improvement and development, however, is beset with unusual difficulties. The government holds 65 million acres out of the 70 million acres of land in the archipelago. The customs and traditions of the people, the result of six years of warfare, and the depredations of animal diseases, in addition to the primitive methods of agriculture which have been followed, combine to present unusual obstacles in the way of reforms and the establishment of new conditions. This is brought out in other parts of the Commission's report.

It is encouraging to note, therefore, that the letters published in the report show a marked interest and appreciation of the bureau of agriculture, and indicate that there is a considerable element capable of profiting by its work. The efforts of the bureau to get in touch with the more intelligent and progressive persons interested in agriculture have resulted in a mailing list of about 1,000 names; and the distribution of seeds for testing has met with cordial cooperation. The popular publications of the bureau have been well received.

That so encouraging a beginning has been made by the bureau in the short time covered by the report speaks much for the energy and good judgment which have characterized this pioneer undertaking, and augurs well for the future development of the work. A more inviting field, viewed from the opportunity for pioneer as well as more advanced work, could hardly be imagined, and under the liberal policy which evidently prevails toward the bureau of agriculture, it should be a foremost factor in preparing the way for developing the neglected resources of the islands.

VALUES IN SCIENCE.^a

W. H. JORDAN, D. SC.,

Director New York State Experiment Station.

My theme touches the apologetics of applied science. Whatever may be the attitude of scholars who measure values in knowledge from their large and true proportions, we are often made to feel that in the academic world, as well as in the social, many regard science in the abstract as of noble blood, science in use as plebeian. There is no question, I think, but that certain distinctions of "caste" in the domain of knowledge still persistently cling to some of our institutions of learning, fostered perhaps by that dogmatism among educators, not yet wholly extinct, which is said to have denied at one time the privileges of morning chapel exercises to students of science in one of our foremost American colleges. It would be interesting to know whether the Divine Mind sympathized with the view that a study of His material world constituted a sufficient reason for debarring a human soul from His worship! In some colleges and universities, both in this and other lands, a young man seeking to choose a life work as an investigator or teacher would even now be advised earnestly that a study of, and search for, principles in the abstract establishes a man on a plane higher than he can reach if he devotes himself to knowledge in its applied or utilitarian relations.

The judgments of the class room and laboratory affect the verdicts of the drawing room. Mrs. A., whose husband is announced to have solved the problem of the loss of nitrogen from manure, would be decidedly eclipsed by Mrs. B., who could declare with wifely pride that her husband worked out the constitution of some complex organic product. Possibly there are grades of intellectual and social standing within the limits of applied science itself, so that the more common the object toward the study of which scientific knowledge and research are directed, the less the prestige thereby accruing in certain quarters. In fact, it is probably true that the social standing of a scientific effort is more fully determined by the nature of the utilities it is to serve than by comparisons based upon the terms "pure" and "applied."

^a Presidential address delivered at the Washington meeting of the Society for the Promotion of Agricultural Science.

Such distinctions make an impression more or less potent upon the public mind, and, what is more serious, they can hardly fail to exercise a determinative influence upon the conclusions of the student who is casting about for a field of work in which he may let loose his scientific enthusiasms.

Is it true that, viewed in any light whatever, a study of the abstract apart from its relations to concrete phenomena or to considerations of utility offers an opportunity for intellectual achievement and for real usefulness superior to that enjoyed by those who labor in the field of applied science? In attempting to answer this question let us first define terms. Science in general is "knowledge gained by systematic observation, experiment, and reasoning"—it is "knowledge coordinated, arranged, and systematized." This definition includes all knowledge. Pure science is that which treats of laws or general statements apart from particular instances and without reference to any application whatever. Applied science is "science when its laws are employed or exemplified in dealing with concrete phenomena." As particular examples of the former we have the principles of geometry, the laws of heat and light, and the general constitution of the compounds of the fatty series, and the latter is illustrated by applied mechanics, soil physics, our knowledge of nitrogen acquisition and loss in agricultural operations, our understanding of certain fermentations as utilized in technical processes, and the facts of plant and animal diseases. In a very obvious and emphatic sense, science is applied when it is utilized in explaining and directing industrial operations and the practical affairs of life.

It is reasonable to assert, then, that the devotee of pure science seeks knowledge for knowledge's sake, for the love of truth, and that the student of the concrete and the practical must of necessity be inspired more fully by a desire to comprehend the functions of energy and of law and to master their utilities. Our question may be restated in another phraseology: Who stands on the higher plane in the domain of science, the theorist or the utilitarian, the one who uncovers a law or the one who discovers its practical relations and uses?

We are bound to inquire in the first place whether there are inherent differences in the quality and value of knowledge according to its subject-matter. When it appears that science in one department is for any reason more precious than some other class of systematized facts, then we have a good reason for choosing the larger value. But how shall we judge? If we adopt a commercial standard and base our estimates on cost in human effort we shall not find that the men of pure science have acquired all of the highest values. Measured by the expenditure of intellectual energy in securing it, our knowledge of the economics of plant and animal life must be classed among the most precious of the results of modern research. If we measure the

worth and dignity of knowledge by its utility in material things, that is, by its importance to industrial life and its relation to man's physical welfare in giving him increased control over his environment, then it is clear that applied science is in this respect the all-important and triumphant factor of the twentieth-century civilization.

But there are those who protest that these utilitarian applications of knowledge are its inferior uses, and that the true test of its higher value is secured when it becomes an instrument for developing intellectual strength and an inspirational force in stimulating men to high thinking and to the acceptance of lofty ideals. To this protest it may be answered that physical well-being and material prosperity are conditions essential to the nourishment of the best fruits of civilization, and that in contributing to industrial achievements and to the comfort and independence of the individual, science is indirectly a powerful aid in cultivating man's intellectual and moral attributes. More than this, I am not convinced that our higher natures are more profoundly moved by the consideration of principles and law in the abstract than by a contemplation of their operations as manifested in the world of matter and force. A study of mathematics and of the principles of physics is a disciplinary intellectual exercise, but the concrete results of their application in the dynamo, the twentieth century express, the ocean liner, and the Brooklyn bridge arouse our pride, fire our imagination, and stimulate our ambition.

The abstractions of chemistry and of biology appeal with little force to man's esthetic and moral nature, but an insight into the operations of law and the play of forces in their relations to man and his activities not only strengthens us intellectually but points us to the wonderful harmonies of created things, exemplifies and exalts obedience to the Divine edicts, and moves to reverent worship. Abstract truths are cold, inanimate, and devoid of human relation. They may delight the intellectual recluse through the mere pleasure that comes from their mastery, but they are not joined to human need and effort. It is the student of the activities that surround us, from the profound problems of the reproduction and maintenance of life to the devices and instrumentalities with which we earn our daily bread, who feels the pulsations of infinite energy and sees most clearly the essential relations of dependence and control which man sustains. The study of specific problems that touch human living, even though they relate to material welfare, discloses human needs, cultivates the altruistic spirit, and, I am convinced, promotes, as pure science can never do, "the inculcation of those supreme ideals through which the human race is uplifted and ennobled—the ideals of beauty, honor, duty, and love." For we should count science as among the humanities, since it emerged from the laboratory and laid its beneficent hand upon man's daily life and avocations.

The pursuit of science involves not only values but opportunity. The opportunity which the right-minded student desires is a field of work where he may make enduring and beneficent additions to the sum of human knowledge. Can he do this if he is chiefly occupied with the solution of problems important to practical life? I venture the prediction that the greatest contributions to science, even to that which we term pure, during the century upon which we have entered, will flow from the labors of those investigators whose main efforts are directed either to the mastery of Nature's energies as a means of industrial advantage, or to the amelioration and improvement of the conditions of human living. Possibly it is already true that more generalizations of an important character are reached as by-products from the study of specific economic problems than from research that has as its primary object the discovery of abstract principles.

You will doubtless recall that at our last meeting Fries presented new facts concerning the composition of atmospheric air, a direct result of Armsby's researches touching the economics of animal nutrition. The New York Agricultural Experiment Station has been engaged for two or three years in the study of problems important to the cheese industry, out of which have come contributions to chemical knowledge as well as facts that are likely to more fully explain the processes of gastric proteid digestion. The history of the progress of science is full of similar instances where researches having in view purely utilitarian ends have added materially to abstract facts and principles. Properly conducted investigation of specific economic questions can not fail to discover related causes or laws that are of general interest, so that the student in the field of applied science has the almost sure hope of a double reward.

Doubtless there are those who regard these by-products of economic studies that come to us in the formulation of abstract truths as of more value than the solution of the practical problems around which these truths cluster. Few of us would consent to this conclusion, I fancy. The assertion that to know is greater than to act, that abstract truth is a larger value than service, is intolerable in this humanitarian age. Such an assertion is equivalent to the statement that a mode of action is superior to the ends it serves. To accept such a creed is to assent to the doctrine that facts and principles are all sufficient ends in themselves, and are more important as isolated entities than as utilities for promoting human progress and welfare.

We can not condemn too severely an estimate of the value of education and research based solely upon the aid they give to money getting; but we should not confuse this degrading point of view with the instinctive purpose of humanity to use all its acquired powers in securing the most complete adaptation possible to its environment. No result could be more unfortunate than the repression of that

Divine impulse of the human mind to fathom the unknown. The love of truth is fundamental to all research that is worthy of the name, but it reaches the fulfillment of its highest function when there is joined with it the altruistic motive. The scientist who uses the great investigational ability with which he is endowed merely for intellectual gratification or solely for the advancement of his professional standing, has missed the higher ideals of labor and of service.

It is not mere sentiment to declare that the day of exclusiveness and aristocracy in learning is passing, and that the day when the scholar shall serve with dignity in common things is here. In fact, there are no longer things common and unclean in whatever touches human welfare.

The results of scientific research that center around a field of corn or a pail of milk, as an aid to the sustenance and comfort of the human family, possess no elements of inferiority. While we may defend our devotion to science in its practical relations we need not apologize for it. The student may prize such knowledge as he would prize fine gold, and may pursue it even to the attainment of lofty ambitions.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

The determination of phosphoric acid by means of ammonium phosphomolybdate, G. P. BAXTER (*Amer. Chem. Jour.*, 28 (1902), No. 4, pp. 298-315, fig. 1).—The author reports a study of the conditions of precipitation in which he found that a precipitate of constant composition, $(\text{NH}_4)_3\text{PO}_4 \cdot 12\text{MoO}_3$, can be obtained which contains 3.783 per cent of phosphoric acid. The phosphate solution (without large excess of nitric acid) should contain 0.1 gm. phosphoric acid to 50 cc., and should be poured into at least 50 cc. excess of molybdic solution (150 gm. ammonium-molybdate, 1 liter water, 1 liter nitric acid of 1.2 sp. gr.) with vigorous stirring, the mixture being allowed to stand at room temperature for 16 hours. The precipitate is washed with 10 per cent ammonium nitrate solution and heated in a Gooch crucible at least 2 hours at 300° C. A curve is given from which the phosphoric-acid content for different weights of precipitate may be obtained. Precipitation may be hastened by the addition of ammonium nitrate (10 gm. to 100 cc. of molybdic solution) without appreciably affecting the results.

Determination of phosphoric acid in Wiborgh phosphate, M. WEIBULL (*Svensk Kem. Tidskr.*, 14 (1902), p. 135; *abs. in Chem. Abg.*, 26 (1902), No. 90, *Reperl.*, p. 297).—The citrate method was found to give too high results, due to simultaneous precipitation of silicic acid. This was prevented by adding to the solution before precipitation with magnesia mixture a 20 per cent iron chlorid solution at the rate of 0.1 gm. of iron to 0.5 gm. of substance, and 2 drops of bromin water if the solution smells of hydrogen sulphid.

Methods for the determination of total phosphoric acid and potash in soils, C. B. WILLIAMS (*Abstr. in Science*, n. ser., 17 (1903), No. 418, p. 29).—The method proposed for phosphoric acid is as follows: After igniting 5 gm. of soil in a platinum dish, treat 3 times with hydrofluoric acid, evaporating to dryness each time. Fuse with 10 gm. of a mixture of equal parts of sodium and potassium carbonate, and after cooling the cake thus obtained transfer it to a beaker and digest with 30 to 40 cc. of (1 to 1) hydrochloric acid. Evaporate the solution to dryness on a water bath, heating subsequently for 4 or 5 hours in an air bath to 110° C. to dehydrate silica. Take up in dilute hydrochloric acid, filter, and wash. Add sufficient nitric acid to the mixed filtrate and washings thus obtained to liberate all hydrochloric acid present and evaporate to a volume of 40 cc. Neutralize the excess of nitric acid with ammonia and add 10 to 12 gm. of ammonium nitrate. After cooling add 30 cc. of recently filtered molybdic solution, completing the precipitation by the use of a Wagner shaking machine, and determine phosphoric acid volumetrically by the author's method. ^a

To determine total potash treat 4 gm. of soil in a platinum dish on a water bath, after saturating with dilute (1 to 1) sulphuric acid and igniting, with from 2 to 3 cc. of hydrofluoric acid, 5 times, adding 1 cc. of dilute (1 to 1) sulphuric acid just before bringing to dryness the last time. After the last traces of hydrofluoric acid

^a*Jour. Amer. Chem. Soc.*, 23 (1901), p. 8.

have been liberated remove the dish from the water bath and heat gently over a small flame until all evolution of sulphur trioxid ceases. Take up with 20 cc. of distilled water slightly acidified with hydrochloric acid and digest on a water bath until the solution has been reduced to about one-third of its original volume. Then transfer to a 200 cc. graduated flask and heat on a water bath to near the boiling point. Add ammonia and ammonium oxalate in sufficient quantity to precipitate all iron, alumina, and lime present. Cool and make the volume to 200 cc., using an aliquot corresponding to 2 gm. of the original substance for the determination of potash by the Lindo-Gladding method.

On the determination of potash by the modified Finkener method, H. NEUBAUER (*Landw. Vers. Stat.*, 57 (1902), No. 5-6, pp. 461-470).—A defense of the author's modification of Finkener's method (*E. S. R.*, 12, p. 714) against a criticism of it by the fertilizer section of the German Association of Experiment Stations.

The supposed loss of potash in incineration, R. Woy (*Ztschr. Offentl. Chem.*, 8 (1902), pp. 389-394; *abs. in Chem. Centbl.*, 1902, II, No. 24, p. 1429).—In incinerating wine argols the author found no metallic potassium (as claimed by Barth) in the gaseous products of combustion, although titration of the potassium carbonate formed showed an apparent loss of 20 per cent potash in some form. Gravimetric determination showed no such loss. The apparent loss was due to the formation of sulphate and traces of nitrate of potash by the products of combustion of the gas used in the incineration and their deposition on the upper part of the dish.

The determination of the active constituents of marl and limestone, H. BODE (*Fühling's Landw. Ztg.*, 51 (1902), Nos. 20, pp. 729-733; 21, pp. 771-780).—Various methods which have been proposed for the analysis of these substances are discussed. The method found most satisfactory is to heat 1 gm. of the substance with 50 cc. of 10 per cent acetic acid until bubbles of carbon dioxid cease to be given off (usually $\frac{1}{4}$ hour), dilute to 100 cc., and use 25 to 50 cc. of the solution for the determination of lime and magnesia. Tests of the method on a variety of calcareous substances indicate that it furnishes a very accurate means of determining the lime and magnesia combined with carbon dioxid and hence in more available form.

On a new apparatus for the determination of nitrogen, C. PORCHER and M. BRISAC (*Bul. Soc. Chim. Paris*, 3. ser., 27 (1902), No. 22, pp. 1128-1130, fig. 1).—An apparatus for the determination of nitrogen in ammoniacal salts by decomposition with hypobromid is described.

The analytical methods for carbohydrates as applied to foods and feeding stuffs, W. H. KRUG (*Jour. Franklin Inst.*, 154 (1902), Nos. 5, pp. 349-366; 6, pp. 401-422).—The author gives general methods for the determination of water-soluble carbohydrates, starch, pentosans, and galactan, and special methods used in the examination of the following food products with reference to the detection of adulteration: Meats and meat products, milk and milk products, flour and breadstuffs, sugars, fruit products, confectionery, beer, malt extracts, wines, distilled liquors, coffee, cocoa, spices, and condiments.

Study of methods of cattle food analysis, C. A. BROWNE, Jr., and C. P. BEISTLE (*Pennsylvania Sta. Rpt.* 1901, pp. 117-122).—Determinations of the moisture, starch, pentosan, and galactan contents of 1 sample of wheat, 2 of bran, and 1 of clover seed are reported. The work was done for the Association of Official Agricultural Chemists for the purpose of testing methods, and noted in the report of the referee upon this subject (*E. S. R.*, 13, p. 410).

The Halphen reaction and its value in the examination of butter, B. SJOLLEMA and J. E. TULLEKEN (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 5 (1902), No. 19, pp. 914-916).—The same coloration was obtained with butter from cows fed cotton-seed meal as with cotton-seed oil.

The Wijs method of determining the iodine value of oils and fats, T. F. HARVEY (*Jour. Soc. Chem. Ind.*, 21 (1902), No. 23, pp. 1437-1439).—The results of

tests of the Wijs method of determining the iodine value of oils and fats are reported. This method is considered as having many advantages over that of Hübl, chief among which is the great stability of the solution used. The procedure is practically the same in the 2 methods. The iodine values of a number of oils determined by the Wijs method are given.

Determination of boric acid in margarin, A. BENTHIEU (*Ztschr. Untersuch. Nahr. u. Genussm.*, 5 (1902), No. 16, pp. 764-766).—From 50 to 100 gm. of margarin is well shaken with 50 cc. of hot water and filtered through a dry filter. The filtrate, of which 40 cc. can usually be obtained, is neutralized with deci-normal sodium hydroxid, phenol-phthalein being used as an indicator. After the addition of 25 cc. of glycerol the titration is completed.

Determination of alcohol in very dilute solutions, G. ARGENSON (*Bul. Soc. Chim. Paris*, 3. ser., 27-28 (1902), No. 18-19, pp. 1000-1003).—In the colorimetric method given, the alcohol is converted into aldehyde and a few drops of an aqueous solution of fuchsin decolorized with anhydrous sulphuric acid is added when a violet color appears. An appreciable coloration is obtained in solutions containing originally 1 part of alcohol in 10 million by volume.

Observation on the occurrence and properties of cholin, H. STRUVE (*Ztschr. Analyt. Chem.*, 41 (1902), No. 9, pp. 544-550).—This article deals with the occurrence of cholin in grapevine sap and in tartar, and also with the quantitative estimation of cholin.

On the determination of carbon monoxid and carbon dioxid in vitiated air, F. JEAN (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 18, pp. 746-748).—A simple automatic apparatus for this purpose is described. The apparatus consists essentially of 3 connected flasks, through which the air is drawn. The first is closed with absorbent cotton and filled with sulphuric acid to filter the air and remove dust particles and volatile organic matter; the second contains dilute potash or soda solution (colored with Poirrier Blue, C_4B) to remove carbon dioxid; the third, palladium chlorid or ammoniacal silver nitrate, which is decomposed by carbon monoxid and thus furnishes a measure of the quantity of this gas present. Knowing the quantity of each gas required to cause the characteristic reaction with the solutions used (change of color in the alkaline solution and metallic deposit in case of the palladium or silver solution), and measuring the amount of air which it is necessary to draw through before the reaction is brought about, it is easy to calculate the proportions of carbon monoxid and dioxid present.

Observations on the analysis of atmospheric air, O. REBUFFAT (*Gaz. Chim. Ital.*, 32 (1902), II, pp. 153-157; *abs. in Chem. Centbl.*, 1902, II, No. 23, p. 1390).—Methods used in examining the air over fields fertilized with night soil are described.

Miscellaneous analyses, M. E. JAFFA (*California Sta. Rpt.* 1899-1901, pt. 2, pp. 235, 236).—This includes analyses of gluten flour, wheat, Wheatine, fruit-preserving liquid, peat, yadoo fiber, meat meal, blood meal, and fish refuse.

International catalogue of scientific literature. D—Chemistry (*Internat. Cat. Sci. Lit.*, 2 (1902), pt. 1, pp. 468).—This catalogue is being prepared by a central bureau in London under the directorship of H. F. Morley and by 29 regional bureaus in different countries. The supreme control of the catalogue is vested in an international convention, to meet in London in 1905, 1910, and every tenth year thereafter. In the interval between successive meetings the administration is vested in an international council consisting of one representative from each regional bureau. The plan adopted provides for author and subject indexes for the different branches of science, which have been arranged in 17 groups. This volume, for which E. Goulding is referee, is an incomplete index of the literature of chemistry during 1901, the publication of the second part of the volume being promised in a few months.

Chemicals and allied products, C. E. MUNROE and T. M. CHATARD (*Twelfth*

Census United States, Census Buls. 210, 210a, pp. 306; Census Rpts., Vol. 10 (Manufactures, pt. 4), pp. 523-679, 831-978).—This is a statistical report on the manufacture of chemicals and allied products in the United States, from which it appears that a capital of \$238,529,641 was invested in the industry in 1900. The aggregate value of the products was \$202,582,396. The products included in this report are classified into 19 groups, as follows: Acids, soda products, potashes, alums, coal-tar products, cyanids, wood distillation, fertilizers, bleaching materials, chemical substances produced by the aid of electricity, dyestuffs, tanning materials, paints, explosives, plastics, essential oils, compressed and liquefied gases, fine chemicals, and general chemicals. The number of establishments reported as engaged exclusively or in part in the manufacture of fertilizers in 1900 was 478, the total product being 3,091,717 tons, valued at \$46,011,382, thus showing an increase of over 50 per cent in quantity and 20 per cent in value since the previous census. The industry is distributed as follows: North Atlantic States, 155 establishments producing 685,893 tons; South Atlantic States, 198 establishments producing 1,531,688 tons; North Central States, 63 establishments producing 258,726 tons; South Central States, 39 establishments producing 352,778 tons; Western States, 9 establishments producing 22,131 tons; all other States, 14 establishments producing 35,788 tons. The production of superphosphate is reported as 937,008 tons, ammoniated superphosphate 143,648 tons, and complete fertilizers 1,478,826 tons, valued respectively at \$8,592,360, \$2,462,888, and \$26,318,995. Among other fertilizers, amounting to 532,235 tons, valued at \$8,637,139, are included 28,977 tons of fish scrap valued at about \$480,000, 160,962 tons of slaughterhouse and meat-packing refuse valued at \$3,326,119, and 17,809 tons of garbage reduction material valued at \$256,322. Of the 1,352,730 tons of sulphuric acid produced in 1900 by 127 establishments in the United States, 654,966 tons was furnished by 79 fertilizer establishments, which used 583,859 tons of the acid in the manufacture of superphosphates. The valuation of the natural and artificial tanning materials produced was \$1,899,220. A digest of patents relating to chemical industries, prepared by S. B. Ladd, is included.

BOTANY.

Chlorophyll assimilation at low atmospheric pressures, J. FRIEDEL (*Rev. Gén. Bot.*, 14 (1902), Nos. 164, pp. 337-355; 165, pp. 369-390, figs. 5).—The author has investigated the influence of pressure of rarefied air, and of atmospheres in which the amount of carbon dioxide and oxygen was varied according to definite proportions. It was found that the diminution of pressure does not as a rule influence the nature of chlorophyll assimilation, but in some cases does affect its intensity. The phenomena of assimilation under the conditions of the experiment seem to be the dependent on two forces, the total pressure and the relative pressure of carbon dioxide. The relative pressure of oxygen has no influence on assimilation. Among evergreen shrubs the total atmospheric pressure was without influence, while the influence of the carbon dioxide pressure varied with the age of the leaves. An increase in atmospheric volume favored assimilation if the pressure remained constant. If the volume and pressure were successively varied or if modified simultaneously the result was the same. Assimilation at low pressure was carried on normally by an entire plant of *Lapidium sativum*, and the leaves of the black locust were influenced in the same way as the young leaves of the evergreen shrubs *Ruscus aculeatus*, *Euonymus japonicus*, and *Ligustrum japonicum*.

The injurious effect of smoke and gases on plant growth, E. HASELHOFF and G. LINDAU (*Die Beschädigung der Vegetation durch Rauch*. Leipzig: Borntraeger Bros., 1903, pp. VIII+412, figs. 27).—The rapid extension and development of various chemical, manufacturing, and other industries the works of which give off large amounts of smoke, gases, etc., have been attended with much injury to trees and other vegetation. These injuries have been extensively studied by the authors and

many others, and the information is brought together in what is called a handbook for the recognition of the injury and estimation of damage done by smoke, gases, and similar agents. After a general discussion of the various sources and kinds of injurious smoke and gases, the authors consider a number of them in detail, chapters being devoted to the injury caused by sulphurous and sulphuric acids, chlorine and hydrochloric acid, hydrofluoric, nitric, and acetic acids, ammonia, bromine, coal tar and its products, asphalt, illuminating gas, etc. Means for preventing some of the injuries are discussed, and an extended bibliography of references to the literature of the subject completes the work.

Injurious effects of premature pollination, C. P. HARTLEY (*U. S. Dept. Agr., Bureau of Plant Industry Bul. 22, pp. 48, pls. 4, fig. 1*).—The investigation here reported seems to indicate that decidedly injurious effects may be obtained by premature pollination, showing the necessity of careful consideration as to the time for applying pollen to the stigmas in experiments in plant breeding. The author conducted experiments with tobacco, cotton, orange, and tomato flowers, contrasting the effects of immature and mature pollinations. It was found that flowers which mature their pistils before their stamens were uninjured by premature pollination, while those that mature their anthers and stigmas at the same time were injured. The application of good tobacco pollen to immature tobacco pistils caused the flowers so treated to fall from the plant because of the growth of the pollen tubes into their ovaries. Somewhat similar results were obtained with tomatoes, only 2 out of 40 blossoms setting fruit when prematurely pollinated. Tobacco and tomato plants were found to sometimes set and ripen fruits without the flowers having received any pollen, but such occurrences were rare and the fruits contained no fertile seeds. The experiments described show that while some flowers can be successfully pollinated at the time emasculation of the flower is performed, others can not, and no arbitrary rules of procedure can be given for all flowers.

Mendel's principles of heredity. A defense, W. BATESON (*Cambridge Univ. Press, 1902, pp. 212*).—The author presents a translation of Gregor Mendel's experiments in plant hybridization (*E. S. R.*, 13, p. 744) and answers by argument Weldon's criticisms (*E. S. R.*, 14, p. 446) of Mendel's work. The problems of heredity are stated and their solution discussed. A bibliography of 36 papers on hybridization is appended.

Experimental studies in the physiology of heredity, W. BATESON and Miss E. R. SAUNDERS (*Rpts. to Evolution Com., Roy. Soc. [London], 1902, pp. 160; abs. in Bot. Centbl., 90 (1902), No. 37, p. 291*).—The results of extensive breeding experiments with poultry and plants are given. So far as the results of the experiments with plants are concerned, the phenomena observed in *Lycchnis*, *Atropa*, and *Datura* follow Mendel's law with considerable accuracy, and no exceptions were discovered that did not appear to be merely fortuitous. In the case of the experiments with *Matthiola* the phenomena were much more complex. In some cases the results followed Mendelian principles, while in others they seemed to depart, but could be grouped into fairly definite classes, but their nature was obscure. The paper concludes with a general discussion of heredity as exemplified by Mendel's law.

Variation in *Trillium grandiflorum*, H. W. BRITCHER (*Maine Sta. Bul. 86, pp. 169-196, pls. 5*).—A record is given of the variations observed in 185 specimens of *Trillium grandiflorum*.

Comparative anatomy of the styles and stigmas of phanerogams, F. GUÉGUEN (*Jour. Bot. [Paris], 16 (1902), Nos. 1, pp. 15-30; 2, pp. 48-65; 4, pp. 138-144; 5, pp. 167-180; 8, pp. 280-286; 9, pp. 300-313, pls. 22*).—Results of an extensive study of the anatomical structure of the styles and stigmas of the phanerogams are given, the notes being arranged according to plant families. As a rule the complexity of the tissues of the styles increases with the greater specialization of the plant. The stigmas and stigmatic surfaces are less constant in their structure, being modi-

fied for the various conditions under which they secured pollination. As a rule those families of plants in which cross fertilization is usual have stigmas bearing a marked similarity throughout the group.

The morphology and physiology of the germination of Spermatophytes, A. J. J. VANDEVELDE (*De kieming der Zaadplanten, morphologie en physiologie. Ghent: J. Vuytsteke, 1900, pt. 2, pp. 137-301, figs. 28*).—Part 1 of this work, which appeared in 1897 (*E. S. R.*, 9, p. 526), was mostly taken up with a bibliography of the subject. In the present contribution the morphology of germination is discussed at considerable length, as is also the physics and physiology. The bibliography quoted in the first part is added to, and reviews are given of the extensive literature relating to this subject.

Studies on tuber formation, N. BERNARD (*Rev. Gén. Bot.*, 14 (1902), Nos. 157, pp. 5-25; 158, pp. 58-71; 159, pp. 101-119; 160, pp. 170-183; 161, pp. 219-235; 162, pp. 269-279, pls. 3).—The author designates by the term tuberization the special development which is characterized by the slow morphological and histological differentiation of vegetative points of growth or buds, and which serve for the storing up of reserves not utilized by the differentiation. He has examined quite a number of species of orchids, ranunculus, potatoes, and other tuber-forming plants, and finds their roots normally infested with filamentous fungi which are apparently of the genera *Nectria*, *Hypomyces*, and others. On account of the constant presence of the fungi the author believes that they are a requisite to the formation of tubers. He has divided the different methods of tuber formation into 3 categories: Precocious tuberization, in which the infection of the plant takes place at the time of germination and continues throughout the life of the plant; tuberization which is precocious and periodic, in which there appear to be alternate periods of infection and noninfection; and late periodic tuberization, in which the infection is not realized until a considerable time after germination. This last form is the one observed in the case of the potato, the others being illustrated by various species of orchids.

Electric response in ordinary plants under mechanical stimulus, J. C. BOSE (*Jour. Linn. Soc. [London], Bot.*, 35 (1902), No. 245, pp. 275-304, figs. 25).—A series of experiments was conducted to determine whether the response phenomena showed a parallelism between animal and vegetable life. It was desired to ascertain the relation between the intensity of stimulus and the corresponding response on the part of the plants, and the effect of various stimuli such as chemicals, temperature, anesthetics, etc. The experiments were conducted upon the roots, stems, leaf-stalks, flower stalks, and fruits of a number of plants, and the results obtained indicate that the electric record gives an unfailing indication of the modification of the plants' vitality under the influence of various external agencies. The electric response is shown to be a faithful index of physiological action, and the response was found to be modified by any influence which affected the vitality of the plant.

A method of investigating the gravitational sensitiveness of the root tip, F. DARWIN (*Jour. Linn. Soc. [London], Bot.*, 35 (1902), No. 245, pp. 266-274, figs. 9; *abs. in Bot. Centbl.*, 90 (1902), No. 11, p. 295).—A method is described for investigating the sensitiveness of the root tip of plants to the influence of gravity, which consists of fixing the root tip by means of a tube in a horizontal position so that the cotyledons and hypocotyl are free to move. These organs are so supported by a counterbalance that when geotropic curvature of the root begins, the cotyledons move, in some cases traveling through as much as a 180° arc. The experiments showed that there was a strong tendency in the case of the root of the bean and pea to continue curving when the tip was fixed horizontally and the other end of the seedling was free to move. The results obtained are based on the assumption that the tip is the only part of the root which is sensitive to gravity.

Root pressure in Begonia, J. B. DANDENO (*Science, n. ser.*, 16 (1902), No. 412, pp. 833-835).—An account is given of experiments with a vigorous growing *Begonia*

plant in which the stem was cut about 3 in. above the surface of the soil in the flower pot, and a glass tube firmly connected with it. Through this tube the sap was forced to a height of 9 ft. 10 in., the total amount of sap passing through the tube being 165 cc. As this phenomenon is usually accounted for by osmotic pressure of the cell sap, the author believes that in this case it could be hardly due to that alone, as the sap in the glass tube was of a too dilute solution. The results obtained are believed to be far in excess of that indicated in van't Hoff's law.

The occurrence of calcium oxalate crystals in seedlings of alsike clover, J. PERCIVAL (*Jour. Linn. Soc. [London], Bot.*, 35 (1902), No. 245, pp. 396-402, figs. 6).—An examination was made of the seedlings grown on filter paper moistened with distilled water, and it was found that the crystals of calcium oxalate appear along the vascular bundles in the petioles of the cotyledons and are distributed evenly along their length. With increasing age a few crystals may be noticed along the vascular bundles which run through the cotyledons; and as soon as the primary leaves appear, crystals may be found in them lying near the vascular bundles. In seedlings grown in a very damp atmosphere, the crystals diminish in number proportionately.

On the localization of daphnine in *Daphne laureola*, W. RUSSELL (*Rev. Gén. Bot.*, 14 (1902), No. 166, pp. 420-426).—The laurel, or laurel spurge (*Daphne laureola*), is a common undershrub of Europe and is reputed as being poisonous as well as having certain medicinal characters. A study has been made of the different parts of the plant to determine the localization of the alkaloid daphnine. This substance was found localized in the epidermis of the older organs of the plant, in the cortex and ligneous rays of the stem and leaves, and in a small quantity in the roots. It is always accompanied by oleaginous deposits, which are quite characteristic of this plant.

Report of the botanist, C. E. BESSEY (*Nebraska State Bd. Agr. Rpt. 1901*, pp. 95-129, figs. 16).—A preliminary account is given of the plants of Nebraska which are reputed to be poisonous or suspected of being so. The plants are arranged according to families, and each species briefly discussed, after which a list is given of the poisonous plants arranged according to their effect.

A catalogue of the grasses of Belgium and their fungus parasites, H. VANDERYST (*Bul. Agr. [Brussels]*, 18 (1902), No. 6, pp. 1044-1059).—A list of grasses found indigenous and growing under cultivation is given, together with an enumeration of their rust and smut parasites.

Notes on plants received for identification and their economic value, J. B. DAVY (*California Sta. Rpt. 1899-1901*, pt. 2, pp. 345-383).—Notes are given on a large number of plants which have been received from time to time for identification, and suggestions offered relating to their economic value. In addition, lists are given of seeds and plants received at the station, as well as of the exchanges which have been carried on between that and other institutions.

Studies on the reproduction of some of the higher fungi, A. DE GOMONT DE LESPARRE (*Étude sur la reproduction sexuelle de quelques champignons supérieurs. Paris: Paul Klinksieck, 1902*, pp. XX+61, pls. 3, figs. 16; rev. in *Jour. Roy. Micros. Soc. [London]*, 1902, No. 4, pp. 472, 473).—A historical account is given of the sexual development and growth of truffles, the various speculations regarding the origin and nature of this organism being noted in some detail. The question of the parasitism of truffles is discussed and the author believes that while truffles sometimes live as parasites on the roots of trees they grow equally well as saprophytes in the soil. He has found that the spores germinate on the leaves of trees such as oaks, walnuts, etc., and usually near the central vein of the leaf. They are transmitted to the leaves by insects or by such mechanical agents as the wind. The most favorable time for germination is in December when the leaves are fresh and green, often being still retained upon the tree. The germination and sexuality of the spores are described, and the results of experiments with other Hymenomycetes are given.

A monograph of Amanita and Lepiota, L. QUÉLET and F. BATAILLE (*Flore monographique des Amanites et des Lépiotes*. Paris: Masson & Co., 1902, pp. 88).—Analytical keys are given for the species of Amanita and Lepiota, with directions for distinguishing between the edible and poisonous species, and suggestions for treatment in case poisonous species are eaten. The general habits of these mushrooms, their qualities, and preparation for food are described.

A simple respiration apparatus, H. H. DIXON (*Notes Bot. School, Trinity Col., Dublin, 1902, No. 5, pp. 194, 195, fig. 1*).—A form of apparatus is described which consists essentially of 2 globes connected by a U-tube, a cross arm connecting the upper portion of the tube for the transmission of gases. This is adapted to use with various small objects in which the evolution of carbon dioxide is to be shown.

Biological laboratory methods, P. H. MELL (*New York: The Macmillan Co., 1902, pp. XIV+321, figs. 131*).—The author gives full and clear instructions concerning the use of the microscope and other instruments, and methods required in the modern biological laboratory. The present manuals are considered too voluminous for the needs of many institutions and not sufficiently detailed for many students. Chapters are devoted to the microscope and its accessories, and directions given for the preparation of tissues for sectioning and mounting, their staining and preservation. The apparatus for the preparation of photo-micrographs is described and the methods adopted for their preparation are given in considerable detail. The apparatus and methods for use in bacteriological studies are also given, together with numerous formulae for preparations used in microscopic investigations and suggestions for the arrangement and equipment of laboratories and their furniture.

Sectioning without embedding, H. H. DIXON (*Notes Bot. School, Trinity Col., Dublin, 1902, No. 5, pp. 189-193*).—The author states that if leaves or herbaceous stems be hardened in alcohol for a few days or if woody stems be softened by immersing them in a mixture of glycerin and alcohol they may be readily sectioned with a microtome if securely clamped between 2 flat pieces of cork or pith. In this way he has been able to prepare sections of sufficient thinness to admit of careful histological investigations.

International catalogue of scientific literature. M—Botany (*Internat. Cat. Sci. Lit., 1 (1902), pt. 1, pp. 378*).—This catalogue is an outgrowth of the catalogue of scientific papers hitherto published by the Royal Society of London. The branches of science treated have been divided into 17 groups, each of which is to be catalogued separately. A decimal system of classification has been adopted, and both author and subject indexes are given, about 2,000 publications being listed for the year covered by the catalogue. An examination of this catalogue shows a decided lack of references to American publications, which it is hoped will be corrected in the second part, which is promised.

METEOROLOGY.

Meteorological observations, A. O. LEUSCHNER and J. D. MADDRILL (*California Sta. Rpt. 1899-1901, pt. 2, folders opp. p. 388*).—This is a synopsis of observations at Berkeley on atmospheric pressure, temperature, precipitation, relative humidity, cloudiness, and direction of the wind during the 2 years ended June 30, 1901.

Meteorological observations, J. E. OSTRANDER and S. C. BACON (*Massachusetts Sta. Met. Buls. 163-168, pp. 4 each*).—Summaries of observations on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during July-December, 1902. The general character of the weather of each month is briefly discussed, and the December bulletin gives a summary for the year. The principal data in this summary are as follows:

Pressure^a (inches).—Maximum, 30.75, December 15; minimum, 28.86, February 2, February 17; mean, 29.954. *Air temperature*^b (degrees F.).—Maximum, 91, May 23;

^a Reduced to freezing and sea level.

^b In ground shelter.

minimum, —15, December 10; mean, 47.3; mean sensible (wet bulb), 43.1; maximum daily range, 54, December 10; minimum daily range, 3, November 27; mean daily range, 20.7. *Humidity*.—Mean dewpoint, 37.7; mean relative humidity, 71.6. *Precipitation*.—Total rainfall or melted snow, 46.99 in.; number of days on which 0.01 in. or more rain or melted snow fell, 144; total snowfall, 57 in. *Weather*.—Total cloudiness recorded by sun thermometer, 2,589 hours, or 58 per cent; number of clear days, 73; number of fair days, 113; number of cloudy days, 179. *Bright sunshine*.—Number of hours recorded, 1,864, or 42 per cent. *Wind*.—Prevailing direction, NW.; total movement, 48,438 miles; maximum daily movement, 596 miles, March 19; minimum daily movement, 3 miles, December 7; mean daily movement, 132.7 miles; maximum pressure per square foot, 24 lbs., February 3, NNW.; March 19, ENE. *Dates of frost*.—Last, May 14; first, September 6. *Dates of snow*.—Last, April 2; first, October 29.

Meteorological observations in Nebraska during the year 1901, (i. D. SWEZEY (Nebraska State Bd. Agr. Rpt. 1901, pp. 201–238).—The general characteristics of the weather of each month of the year are discussed and detailed data of observations on temperature, precipitation, cloudiness, and direction of the wind at 159 places in Nebraska are given in tables. "The average atmospheric pressure for the State was 30.02 in., which is 0.04 in. below the normal. . . . The mean annual temperature for the State was 50.1°, which is 1.7° above the normal. . . . The average total precipitation over the State for the year was 22.76 in., which is 0.46 in. below the normal. . . . The prevailing direction of the wind was from the northwest.' The most remarkable feature of the weather of the year was the almost unbroken record of high temperature during July, "100° being recorded at some place in the State on every day of the month, and several stations reported 100° or over on 20 to 28 of the 31 days of the month."

Meteorology, C. W. NORRIS (Pennsylvania Sta. Rpt. 1901, pp. 195–207, 397–435).—The observations here recorded are of the same character as those reported in previous years (E. S. R., 13, p. 720). Monthly summaries of observations are given in the body of the report and the detailed record in an appendix. The summary for 1900 is as follows:

Summary of meteorological observations, 1900.

	1900.	Growing season (Apr.–Sept.).
Barometer (inches):		
Mean	30.044	
Highest	30.633 (Feb. 27)...	
Lowest	29.220 (Feb. 22)...	
Temperature (° F.):		
Mean	50.4	65.8.
Highest	96 (July 17).....	96 (July 17).
Lowest	—3 (Feb. 25).....	22 (Apr. 11).
Mean daily range	18.2	21.7.
Greatest daily range	37 (May 6–27).....	37 (May 6, 27).
Least daily range	2 (Dec. 6).....	
Mean daily relative humidity (per cent)	79.2	75.4.
Rainfall (inches):		
Total	31.75	13.71.
Greatest monthly	4.1 (Nov.).....	
Greatest daily	1.86	1.11 (May 19).
Number of days on which 0.01 in. or more of rain fell	128	58.
Mean percentage of cloudiness	44.8	36.
Number of days on which cloudiness averaged 80 per cent or more	92	28.
Average hours of sunshine per day		8 h. 5 m.
Maximum velocity of wind per hour (miles):	35 (Dec. 13).....	
Last frost in spring		May 10.
First frost in fall		Sept. 19.

Meteorological observations made at the meteorological observatory of the Technical Institute of Verona during 1901, G. FRACASTARO (Atti e Mem. Accad. Agr., Sci., Let., Arti e Com. Verona, 4. ser., 2 (1901–2), pp. 293–341).—A

detailed tabular record of daily observations on atmospheric pressure, temperature, precipitation, humidity, cloudiness, direction and velocity of the wind, and casual phenomena.

Rainfall at the Manurial and Variety Experiment Stations, Barbados, from December, 1900, to April, 1902 (*Rpt. Agr. Work, Imp. Dept. gr. West Indies, 1900-1902*, pp. 4, 121, 122).—The monthly rainfall at 14 different places in Barbados is reported.

Composition of Barbados rainfall (*Rpt. Agr. Work, Imp. Dept. Agr. West Indies, 1900-1902*, p. 2).—The total amount of rainfall and its content of chlorine and of nitrogen in different forms are reported for each month from December, 1900, to May, 1902, inclusive.

WATER—SOILS.

A laboratory study of the percolation of water through soil, A. V. STUBEN-RAUCH (*California Sta. Rpt. 1899-1901*, pt. 2, pp. 153-172, figs. 7).—The percolation experiments reported "were conducted in the usual way, i. e., in glass cylinders filled with the soils (air-dried) under investigation, the rate of flow being easily obtained by measuring the progressive wetting of the soil." In these experiments tests were made of the influences on percolation of the diameter of the tubes ($5, 2\frac{3}{4}, \frac{3}{4}$, and $\frac{1}{8}$ in.); wetting the soil and drying it at 100°C . and allowing to dry normally; repeated wetting and drying; the use of a vent-tube or a cloth bottom to the cylinders; different methods of filling the cylinders; and tamping or keeping the surface loose.

The results show that the rate of flow is not materially affected by the diameter of the cylinders, but it is difficult to secure uniform results with cylinders of small diameters. Drying at 100°C ., repeated wetting and drying either at 100°C . or normally, and tamping the surface retarded percolation. As a result of these observations the author recommends cylinders of $1\frac{1}{2}$ in. diameter and 40 in. long. The following arrangement was found satisfactory: "The bottom of the cylinder was sunk to the depth of one-quarter inch into a thick (2 in.) block of wood, by first boring out a hole of the same diameter as the outside of the cylinder. In the bottom of this hole a smaller one corresponding to the inside diameter of the cylinder was bored to a depth of 1 in. This smaller hole thus formed a cavity beneath the cylinder, from which an outlet tube was provided. The cavity in the block was well paraffined and waxed to make it water-tight, and filled with coarse fragments of granite, over which was pasted a perforated disk of filter paper. The cylinder [provided with a cloth bottom] was filled to the proper mark and secured on top so as to allow it to be inverted. The cloth bottom was removed, and the block of wood put in place—also inverted. Then by simply turning the whole arrangement upright, the column of soil rested on the layer of granite fragments, unexposed to light and with a minimum exposure to air.

"The outlet tube led into a weighed flask, provided with a vent-tube drawn to a fine opening to avoid evaporation while allowing the air to escape. The water was maintained automatically at a depth of one-half inch on top of the soil by means of a Mariotte arrangement; thus evaporation was avoided, and entrance of air at the top end of the cylinder permitted as in receiving flasks. . . .

"The old method of filling in the soil piecemeal was discarded as likely to lead to nonuniform conditions in the cylinders. Instead, the entire quantity of soil was weighed out and placed on a sheet of stiff paper a trifle longer than the cylinder. There it was thoroughly mixed and spread out in a long, narrow strip. The paper was rolled up around this strip of soil, forming a cylinder small enough to fit into the glass tube. By pushing the paper roll of soil as far as possible into the cylinder lying horizontally, and then quickly turning the whole into a vertical position, the soil was dropped in the cylinder in one mass. The paper was then carefully and slowly drawn out, the cylinder being tapped gently all the while. In this way the

soil was easily and uniformly brought down to the mark, and all the old trouble with the uneven distribution of the soil particles, when poured into the cylinders, was avoided.

"The standard of compactness for each class of soils was obtained by weighing the quantity which could be conveniently settled or compacted into 100 cc. of space by tapping the sides and bottom of the cylinder—not by tamping the soil itself. The weight of the soil thus obtained was adopted as the weight per unit of volume throughout the experiments with that soil."

The results of determinations by this means of the rate of flow through a number of different kinds of soil (black adobe, loam, and sandy soil), the materials dissolved by the percolating waters, and the effect of alkali on percolation are reported in detail in tables and illustrated in diagrams. "The sandy soil, which it was confidently expected would show the fastest rate of flow, was very much the slowest of the three almost from the start, being 62 hours behind the loam and 45 hours behind the black adobe at the 40-in. mark." This is attributed to the fact that the sandy soil had been proportionately more compacted than the others and had a lower percentage of interspace. It was found that a very small difference in the percentage of interspace caused enormous differences in rate of percolation, emphasizing "the extreme liability of laboratory experiments of this kind to variable results, unless a full knowledge and control of all conditions are obtained before comparisons and deductions are made." The amounts of soluble matter removed by the percolating water were large, especially in the first percolates, but data so obtained are not considered a safe basis for estimates of what occurs in nature. The results of the studies of the influence of alkali on percolation were not considered conclusive.

The motions of underground waters, C. S. SLICHTER (*Water Supply and Irrig. Papers, U. S. Geol. Survey, No. 67, pp. 106, pls. 8, figs. 50*).—A preliminary discussion by the same author of experimental and theoretical considerations relating to the movements of underground water has already been noted (E. S. R., 11, p. 519). "The present paper treats of the simpler and more general topics connected with the movements of water underground, being intended to answer the more elementary questions which arise in a consideration of the subject. Examples are given of the various areas in which water occurs underground, the origin and extent of the waters are discussed, and methods of bringing them to the surface and making them available are touched upon. To determine the rate of movement of the underflow the author made a series of observations along the dry bed of the Arkansas River, western Kansas, by the following means: A double row of 1½-in. drive wells was sunk across the channel of the river. The upstream wells were then charged with a strong electrolyte, which dissolved and passed downstream with the moving water. Ammonium chlorid was found most satisfactory for this purpose. The passage of the electrolyte toward the lower well was shown by the gradual movement of the needle of an ammeter, and the final arrival at the well was shown by a sudden and strong deflection of the needle.

Not only are the surface zone of flow and the flow through underground channels, sand, gravel, etc., discussed in this paper, but also the deep zones of flow and the flow through rocks of various kinds, as well as common open wells and artesian and deep wells.

Field operations of the Bureau of Soils, 1901 (third report), M. WHITNEY ET AL. (*U. S. Dept. Agr., Field Operations of the Bureau of Soils, 1901, pp. 647, pls. 96, figs. 25, maps 31*).—This report gives a general review of the work of the Bureau during 1901 by the chief of the Bureau, together with the following papers by assistants in charge of field parties: Soil Survey of the Westfield Area, New York, by R. T. A. Burke and H. W. Marean; Soil Survey of Allegan County, Mich., by E. O. Fippin and T. D. Rice; Soil Survey of the Salem Area, New Jersey, by J. A. Bonsteel and F. W. Taylor; Soil Survey of the Lebanon Area, Pennsylvania, by W. G.

Smith and F. Bennett, jr.; Soil Survey of Prince George County, Md., by J. A. Bonsteel et al.; Soil Survey of Harford County, Md., by W. G. Smith and J. O. Martin; Soil Survey of the Bedford Area, Virginia, by C. N. Mooney, F. O. Martin, and T. A. Caine; Soil Survey of the Prince Edward Area, Virginia, by C. N. Mooney and T. A. Caine; Soil Survey of the Statesville Area, North Carolina, by C. W. Dorsey et al.; Soil Survey of Alamance County, N. C., by G. N. Coffey and W. E. Hearn; Soil Survey of the Cary Area, North Carolina, by G. N. Coffey and W. E. Hearn; Soil Survey of Cobb County, Ga., by R. T. A. Burke and H. W. Marean; Soil Survey of the Covington Area, Georgia, by H. W. Marean; Soil Survey of Montgomery County, Tenn., by J. E. Lapham and M. F. Miller; Soil Survey of the Yazoo Area, Mississippi, by J. A. Bonsteel et al.; Soil Survey of the Yakima Area, Washington, by C. A. Jensen and B. A. Olhausen; Soil Survey of the Boise Area, Idaho, by C. A. Jensen and B. A. Olhausen; Soil Survey of the Hanford Area, California, by M. H. Lapham and W. H. Heileman; Soil Survey of the Lower Salinas Valley, California, by M. H. Lapham and W. H. Heileman; Soil Survey of the Ventura Area, California, by J. G. Holmes and L. Mesmer; Soil Survey of the San Gabriel Area, California, by J. G. Holmes and L. Mesmer; Soil Survey Around Imperial, Cal., by T. H. Means and J. G. Holmes; Soil Survey of the Willis Area, Texas, by J. O. Martin; and Soil Survey of the Lake Charles Area, Louisiana, by W. H. Heileman and L. Mesmer.

The report of the chief of the Bureau deals with the organization of the Division of Soils as a Bureau with largely increased appropriations and facilities for work; the progress, cost, and purpose of the soil survey; and results of the survey, including a discussion of the relation of crops to the type soils examined. During the field season of 1901, 6,557,320 acres, or 10,246 square miles in 15 States, were surveyed and mapped on a scale of 1 in. to the mile as against 3,600,314 acres, or about 5,626 square miles, during the seasons of 1899 and 1900 (E. S. R., 13, p. 924). The average cost of the survey in 1901 was \$2.04 per square mile. The purpose of the soil survey is stated to be "to provide an accurate basis for the adaptation of soils to crops," and the attempt is made in this report, on the basis of the results of the survey of the 10,157,634 acres examined to date, to trace the relation between the different types of soil to various crops. The following table gives the different classes and types of soils which have been surveyed and a partial statement of their crop adaptations:

The classes and types of soils surveyed and their crop adaptations.

Kind of soil.	Number of types.	Total area.	Proportion of total area.	Productive area.	Crops and systems of farming adapted to the soils.
		<i>Acres.</i>	<i>Per cent.</i>	<i>Per cent.</i>	
Stony loam.....	14	385,660	3.80	43	Wheat (30 per cent), dairying (20 per cent), tobacco (14 per cent), peaches (9 per cent).
Gravel.....	6	209,000	2.10	2	Grapes and probably other fruits.
Gravelly loam.....	12	285,476	2.80	63	Wheat (47 per cent), corn (39 per cent), tobacco (14 per cent), citrus fruits (7 per cent), grapes (3 per cent).
Dune sand and sand hill.....	2	40,450	3.05
Sand.....	21	1,454,846	14.30	82	Early truck crops (42 per cent), peaches (24 per cent), tobacco (16 per cent), cotton (7 per cent), sugar beets (5 per cent), grapes (3 per cent), citrus fruits (2 per cent), alfalfa (1 per cent).
Fine sand.....	3	93,500	.90	100	Peaches (55 per cent), truck crops (27 per cent), sugar beets (18 per cent), alfalfa (18 per cent).
Sandy loam.....	36	2,118,593	20.90	93	Alfalfa (23 per cent), wheat (20 per cent), tobacco (18 per cent), corn (16 per cent), cotton (16 per cent), peaches (12 per cent), grapes (9 per cent), citrus fruits (8 per cent), dairying (8 per cent), Lima beans (2 per cent), sugar beets (2 per cent), truck crops (1 per cent).

The classes and types of soils surveyed and their crop adaptation:—Continued.

Kind of soil.	Number of types.	Total area.	Proportion of total area.	Productive area.	Crops and systems of farming adapted to the soils.
		<i>Acres.</i>	<i>Per cent.</i>	<i>Per cent.</i>	
Fine sandy loam	9	549,260	5.40	99	Cotton (52 per cent), alfalfa (29 per cent), early truck crops (19 per cent), rice (10 per cent), tobacco (7 per cent), wheat (5 per cent), grapes (5 per cent), peaches (2 per cent).
Loam.....	29	1,114,890	11	93	Wheat (74 per cent), corn (41 per cent), tobacco (21 per cent), dairying (16 per cent), alfalfa (15 per cent), apples (6 per cent), rice (5 per cent), peaches (2 per cent), cotton (2 per cent), sugarbeets (1 per cent).
Shale loam	4	222,404	2.20	100	Wheat (89 per cent), grapes (8 per cent), corn (1 per cent).
Silt loam	9	756,609	7.40	59	Tobacco (46 per cent), wheat (38 per cent), cotton (16 per cent), alfalfa (7 per cent), barley (4 per cent), sugar beets (3 per cent), Lima beans (1 per cent).
Clay loam.....	12	506,473	5	69	Wheat (69 per cent), tobacco (56 per cent), corn (4 per cent), rice (7 per cent).
Clay	18	1,558,590	15.30	76	Wheat (44 per cent), cotton (28 per cent), dairying (8 per cent), apples (3 per cent), tobacco (2 per cent), sugar beets (1 per cent), grapes (1 per cent).
Adobe	6	158,088	1.60	Wheat (87 per cent), sugar beets (19 per cent), citrus fruits (19 per cent), barley (12 per cent), alfalfa (9 per cent).
Meadow	4	438,758	4.30	Portions liable to overflow, but when protected generally adapted to grasses and corn.
Muck and swamp	6	265,037	2.60	13	Peppermint (13 per cent), celery (1 per cent).

"It is interesting to note that peaches are adapted to 9 per cent of the stony loam, 24 per cent of the sand, 55 per cent of the fine sand, 12 per cent of the sandy loam, 2 per cent of the fine sandy loam, and 2 per cent of the loam, and are not reported as an important crop on any of the other classes of soil. Wheat is reported as an important crop on 34 per cent of the stony loam, 47 per cent of the gravelly loam, 20 per cent of the sandy loam, 5 per cent of the fine sandy loam, 74 per cent of the loam, 89 per cent of the shale loam, 38 per cent of the silt loam, 69 per cent of the clay loam, 44 per cent of clay, and 87 per cent of the adobe. This confirms the general impression that peaches are adapted to loose, open soils of a sandy nature, and to some stony loams, while wheat is best adapted to a loam soil and not so well to heavy clay soils.

"It will be noticed that tobacco is reported as an important crop on a wide range of soils. The reason for this may be found in the fact that different classes of tobacco require very different soils. The light, sandy soils are used in Connecticut for the wrapper-leaf tobacco for domestic cigars, and in Virginia and North Carolina for the bright yellow tobacco. Wrapper leaf is also grown with considerable success in the Connecticut Valley on one of the stony loam soils. In Ohio a filler tobacco for domestic cigars is grown successfully on a gravelly loam, and in Tennessee another type of gravelly loam produces an export type of tobacco. So far as the survey has extended, tobacco is not grown on any of the types of fine sand. It is found, however, on the sandy loams, which in Maryland produce a smoking tobacco, in Virginia a manufacturing tobacco, in Connecticut a cigar-wrapper leaf, and in Pennsylvania a cigar filler. One of the types of fine sandy loam produces a cigar wrapper in Connecticut, and a similar type in North Carolina produces a bright yellow tobacco. The types of loam, silt loam, clay loam, and clay also produce a number of types of tobacco, according to the character of the soil and the climatic conditions. . . .

"It is not to be supposed that the crops given above are the only ones grown upon the several soils; still less that they are the only crops adapted to such soils.

"Where corn is given as an important crop it may well be that wheat and cotton can also be produced. The classification of crops is given more to show the relative agricultural strength of the land than as an indication of the actual acreage of each crop. It should be observed also that climate influences in a very marked degree the crop value of lands, and a soil having the same texture may be adapted to cotton in the South, to wheat in the North, and to alfalfa or sugar beets in the far West. It is not to be assumed, either, that the percentages given will be maintained upon the extension of the soil survey into other areas."

Soil analyses, W. FREAR and C. P. BEISTLE (*Pennsylvania Sta. Rpt. 1901, pp. 137-172*).—Analyses of 2 samples of Cuban tobacco soils (surface and subsoil, manured and unmanured) from the vicinity of Havana, and one of a mica schist soil from Delaware County, Pa., are reported and discussed in detail.

The Cuban soils are of a deep red color and were derived from chalk or limestone formations of a recent geologic period. Their specific gravity was somewhat above the normal for clays, and was much less in the manured than in the unmanured soil. The mechanical analyses indicate that they should be classed as sandy loams, although treatment with a deflocculating agent like 4 per cent ammonia resulted in a complete breaking down of the "sandy" aggregate into the finest clay, the sandy or loamy condition being due apparently to the flocculating action of the lime and magnesia present. The results of the chemical analyses are given in the following table:

Chemical composition of Cuban soils (water-free).

Constituents.	San Antonio.				Zorilla.			
	Unmanured.		Manured.		Unmanured.		Manured.	
	Sur-face.	Sub-soil.	Sur-face.	Sub-soil.	Sur-face.	Sub-soil.	Sur-face.	Sub-soil.

"A general summary of the characteristic qualities of the [virgin] Cuban soils is briefly as follows: These lands are deeper than most American soils devoted to cigar tobacco; they are nearly as porous as the Connecticut sandy soils, but because of their high content of humus and oxids of iron and aluminum, should show a much greater

capacity for absorbing atmospheric moisture; they are rich in nitrogen and phosphoric acid and moderately supplied with potash, but because of the large proportion which the iron oxids and alumina bear to the lime, the phosphoric acid must be very little available, and the conditions are made unfavorable for the renewal of the supply of available potash and nitrates as they are exhausted from the soil. With judicious calcareous manuring, followed later by applications of potash and perhaps of a little soluble phosphate, these lands should show great endurance under intelligent cultivation. . . .

"In the manured lands of each estate the quantities of citric-soluble potash and phosphoric acid are both very much greater than in those unmanured. Especially is the higher amount of lime notable, and its presence as carbonate."

The examination of the mica schist soil showed it to be a ferruginous clay containing a fair supply of fertilizing constituents, but apparently in need of active lime.

Some Cuban soils of chemical interest, W. FREAR and C. P. BEISTLE (*Jour. Amer. Chem. Soc.*, 25 (1903), No. 1, pp. 5-16).—An abridged account (dealing only with virgin soils) of the studies more fully reported in the preceding article.

First report on a chemical and physical study of the soils of Kent and Surrey, A. D. HALL and F. J. PLYMEN (*Southeastern Agr. Col., Wye, Rpt. to Tech. Ed. Com. of Kent and Surrey, 1902, pp. 69, map 1*).—This is a first report on a systematic survey of the soils of these 2 counties, the object of which is to fix the types of soil, trace their boundaries, and ascertain their normal variations. The soils are classified and mapped according to their geological origin. About 80 samples of soil and subsoil were examined wholly or in part as regards physical characteristics and chemical composition and the results are reported, with descriptions of methods employed and suggestions as to the fertilizer requirements and methods of treatment and cropping of the various type soils.

The methods of chemical analysis used are essentially those noted elsewhere (E. S. R., 13, p. 914). The type soils reported on are those of the London clay, chalk, and gault clay.

Results of investigations of Turkestan soils, P. KOSSOVICH ET AL. (*Rpt. Agr. Chem. Lab. Dept. Agr., vol. 3; rev. in Zhur. Oputn. Agron. [Jour. Expt. Landw.], 3 (1902), No. 1, p. 57*).—The report gives the results of a complete analysis of the 10 per cent hydrochloric acid extract of 23 samples, mechanical analyses of 10 samples, and determinations of the principal constituents and an examination of a water extract (alkali salts) of 74 soils and subsoils. Experiments on the soils with wheat, oats, peas, and pines showed that their cultural value depends largely on their alkali content and that of the plants tested the Turkestan wheat was most resistant to alkali while the pine was least resistant.—P. FIREMAN.

Contributions to the knowledge of the soils and the vegetation of Western Siberia, A. GORDYAGIN (*Kazan, 1901; rev. in Zhur. Oputn. Agron. [Jour. Expt. Landw.], 3 (1902), No. 1, pp. 87-90*).—The western part of the basin of the Irtysh River is divided by the author into the following 5 zones from north to south: (1) The podzol covered with firs and pines, (2) wooded chernozem with birch forests, (3) steppe chernozem, (4) the zone of chestnut soils with little forest growth, and (5) desert steppes with light colored soils, *Atriplex canum* being the typical plant.—P. FIREMAN.

Mechanical and chemical examination of soils, R. H. LOUGHRIDGE (*California Sta. Rpt. 1899-1901, pt. 2, pp. 172-189, figs. 4*).—Mechanical and chemical analyses of 4 samples of soils, with discussions of the soil characteristics of the regions from which the samples were obtained, viz, Potter Valley, Arroyo Grande Valley, and San Geronio Pass. There is appended a list of soils received by the station for examination, and of minerals, rocks, etc., sent for identification.

Alkali reclamation at Tulare Substation, C. H. SHINN (*California Sta. Rpt. 1899-1901, pt. 2, pp. 204-214, figs. 7*).—The progress of this work, begun in 1889 (E.

S. R., 10, p. 235), is illustrated in a series of charts which are briefly explained. These show "the gradual amelioration of the worst spots by cultivation and the use of gypsum," also the rise of alkali after several wet seasons or as a result of irrigation on surrounding farms. Gypsum has been used at the rate of about 7.7 tons per acre annually on these soils for 13 years. "In the four years since 1897 the vineyard of 6 acres has received 34,000 lbs. of gypsum, or 17 tons, which is equal to $4\frac{1}{4}$ tons per year. This is a profitable use of gypsum, as the crops have been large and the vines have been kept healthy, for which an annual expenditure of less than \$4 per acre is little to pay."

Alkali and alkali land, R. H. LOUGHRIDGE (*California Sta. Rpt. 1899-1901*, pt. 2, pp. 190-204).—Analyses of water from sulphur and hot springs of the Elsinore Valley; determinations of alkali at different depths in lands bordering Elsinore Lake, and at Tulare and Southern California substations; and results of examinations with reference to alkali in miscellaneous samples of soil from various localities in the State are reported, with brief discussions of the results.

Irrigation, cultivation, and hardpan, E. W. HILGARD (*California Sta. Rpt. 1899-1901*, pt. 2, pp. 149-153).—A brief discussion of the formation of plowsole or hardpan in humid regions, and in arid regions under irrigation, and its injurious effect on the growth of plants.

Fixation of phosphoric acid in the soil, J. T. CRAWLEY (*Jour. Amer. Chem. Soc.*, 24 (1902), No. 11, pp. 1114-1119).—This question was studied on 2 different kinds of soil in boxes 9 in. square and 9 in. deep. The results show "that when the application of the fertilizer [superphosphate] is followed immediately by irrigation (1) more than one-half the phosphoric acid remains in the first inch of soil, more than nine-tenths in 3 in., and practically the whole within 6 in. of the surface; (2) when an interval of 15 hours intervenes between the application and the irrigation, more than nine-tenths of the phosphoric acid is retained by the first inch of soil and practically the whole by the first 3 in."

In further tests of the total capacity of the soil to fix phosphoric acid "800 gm. of red soil and 50 gm. of double superphosphate containing 20.58 gm. water-soluble phosphoric acid were thoroughly mixed together. This mixture was kept moist to promote the chemical action, and samples were withdrawn from time to time to estimate the water-soluble acid." The mixture was made March 26. March 27, 41.6 per cent of phosphoric acid had become fixed; March 29, 57.7 per cent; April 3, 73 per cent; and April 17, 85.65 per cent. Or, taking 3,500 lbs. as the weight of 1 acre of soil to the depth of 1 ft., it was found that this soil absorbed, after 1 day, 35,235 lbs. phosphoric acid per acre to the depth of 1 ft.; after 3 days, 48,872 lbs.; after 8 days, 61,431 lbs.; and after 22 days, 72,545 lbs.

This high absorptive power for phosphoric acid is attributed to the extremely basic character of the Hawaiian soils.

On the fixation of ammonia and potash by Hawaiian soils, J. T. CRAWLEY and R. A. DUNCAN (*Jour. Amer. Chem. Soc.*, 25 (1903), No. 1, pp. 47-50).—In the investigations here reported the same methods were followed as in the studies on fixation of phosphoric acid noted above. When irrigation followed the application of ammonium sulphate one-half of the ammonia was "retained in the first inch, more than four-fifths within the first 2 in., and almost all within 4 in. of soil. . . . The ammonia was held rather firmly, but subsequent irrigations washed it out in decreasing quantities." Under like conditions "seven-tenths of the potash applied [as sulphate] was retained in the first inch, more than four-fifths in 2 in., and almost all within 6 in. of the soil. . . . As in the case of ammonia, the potash was held rather firmly, but irrigations gradually washed it away, 8 irrigations having washed 19 per cent out of 6 in. of soil."

Predominating processes of soil formation, P. SLYEZKIN (*Khozyaĭne*, 1902, pp. 901-908, 921-930; rev. in *Zhur. Opytn. Agron. [Jour. Expt. Landw.]*, 3 (1902), No. 4,

pp. 488-491).—The author discusses the principles of the genetic classification of soils and the complex nature of the processes of soil formation as dependent upon parent rock, temperature, and moisture. The influence of the parent rock is of a passive character, while that of heat and moisture is active, giving rise to a predominating soil process for each climatic zone. Thus near the poles and in arid deserts the predominating process is one of physical weathering, while in other regions chemical and biological actions assist physical action.

In the tropical zone, with a clearly defined sea climate, i. e., high temperature and humidity throughout the year, the predominating processes are chemical and biological, resulting in the formation of lateritic and allied soils.

In subtropical regions, with lower temperature and humidity, the chemical and biological processes are interrupted during the winter, and the predominating process is the accumulation of neutral humus, resulting in the formation of chernozem or alkali soils, according to the character of the parent rock.

In temperate zones, in which the temperature is still lower while the humidity is considerable, the predominating process is one of leaching, resulting in the formation of soils of the podzol class.

The forest soils the author does not consider as a genetic zone. Their origin depends on the replacement of predominating process (accumulation of neutral humus) by another (podzol formation), owing to the change of the balance of humidity in the soil. Marshy and inundated soils depend on the constant or temporary predominance of moisture.—P. FIREMAN.

Report of the geologist, E. H. BARBOUR (*Nebraska State Bd. Agr. Rpt. 1901, pp. 239-266, figs. 6*).—This contains an article on volcanic ash in Nebraska soils, a directory of the limestone quarries of Nebraska (by C. A. Fisher), and a bibliography of the geology of Nebraska. The origin, distribution, nature, and uses of the volcanic ash found generally throughout not only Nebraska, but western Iowa, South Dakota, Oklahoma, Kansas, Colorado, Wyoming, and Montana, and regions farther west are discussed. At present the material "is used for polishing and scouring kitchen ware, and as a base for scouring soap. . . .

"Its chemical composition, according to analyses by Prof. H. H. Nicholson, of the department of chemistry of the State university, is as follows: Organic matter, 8.75 per cent; silica, 68.91 per cent; lime, 3.44 per cent; sodium oxid, 3.09 per cent; potash, 0.36 per cent; sulphuric acid, 8.88 per cent; iron oxid and alumina, 6.12 per cent; total, 99.55 per cent. Geologically this deposit seems to be confined to the more recent deposits, and has not been found below the oligocene, but does occur in beds of varying thickness and extent from that point up to the latest formations."

The location and size or condition of the limestone quarries of the State are given. "The limestone formations in Nebraska are the Niobrara, Benton, Permian, and Carboniferous. The surface area of these formations comprises about a dozen counties in the southeast corner."

The geological bibliography includes an alphabetical list (by authors) of 315 titles of articles on geography, physiography, stratigraphy, resources, water supply, etc., compiled from every available source. "Paleontological papers dealing mainly with the descriptions have not been included in every case."

Effects of different systems of manuring upon the amount and quality of the humus in the soil, W. FREAR and E. H. HESS (*Pennsylvania Sta. Rpt. 1901, pp. 173-186*).—As supplementary to a previous report (E. S. R., 13, p. 330) the results are given of studies of the humus contents of the soil of a series of plats which have for a long period "received applications of 6 tons per acre every alternate year for the corn and wheat in an ordinary four-course rotation of corn, oats, wheat, and grass." The results show that "nearly 20 years of fertilizing by biennial applications of yard manure, in which about 534 lbs. of nitrogen were contained, has resulted in an increase, relative to land cropped identically but receiving no

manure, of 522 lbs. of nitrogen residual in the soil. The relative increase was only about four-fifths as great when lime was applied with the manure. In the case of land receiving complete mineral fertilizers containing, during the period under discussion, 684 lbs. of nitrogen, the relative increase was only about 260 lbs. of nitrogen. . . .

"The experiments of this station show little difference in the proportions between the nitrogen and organic matter on the several manured plats, except that lime has shown a tendency to cause a more rapid loss of the organic matter than of the nitrogen of the manure it accompanies. Where no manure is used, the residual carbon is relatively greater than the residual nitrogen, as compared with the fertilized lands. . . . The use of mineral fertilizers, with and without nitrogen, was attended by an increase of carbon relative to nitrogen; this was more pronounced where yard manure was applied."

The maintenance of soil fertility under the renting system, H. BODE (*Habilschr., Friedrichs-Univ. Halle, 1902, pp. 64*).

Limestones, W. FEAR (*Pennsylvania Sta. Rpt. 1901, pp. 187-191*).—Analyses of 42 samples are reported.

Nitrogen-fixing bacteria, J. G. LIPMAN (*Pop. Sci. Mo., 62 (1902), No. 2, pp. 137-144*).—This is a popular discussion on the source of nitrogen as plant food, nitrification and denitrification in soils, and the fixation of free nitrogen by root tubercles and by soil bacteria independent of leguminous plants. There are, according to the author, about 6 forms of bacteria capable of fixing atmospheric nitrogen known at present, and there is little doubt that others will be found before long.

FERTILIZERS.

Report on experiments with phosphatic fertilizers on winter grain during 1900-1901, O. REITMAIR (*Bericht über die mit Winterhalbfrucht im Herbste 1900 eingeleiteten und 1901 zum Abschluss gebrachten Phosphat-Düngungs-Versuche. Vienna: Landwirtschaftlich-chemischen Versuchstation, 1902, pp. 100, map 1*).—This is an account of a continuation of previous experiments (*E. S. R., 12, p. 839*) in which the action of phosphoric acid in general and of different kinds of phosphates are discussed and 74 cooperative field experiments on rye and wheat in different parts of the Austrian Empire, but principally (about one-half) in German Bohemia, are reported. The phosphatic fertilizers were very effective on winter rye, but much less so on winter wheat. Superphosphate was the most effective form of phosphoric acid used, but Thomas slag was but slightly less effective and was more economical. The Algerian and Belgian phosphates were about equally effective, and in cheapness and effectiveness not very inferior to superphosphate and Thomas slag. The proportion of the phosphoric acid applied taken up by the crop was in no case as high as 10 per cent (with superphosphates 8.2 per cent, with Thomas slag and crude phosphates about 7 per cent). An application of 60 kg. per hectare (53.53 lbs. per acre) of phosphoric acid was abundant for rye and probably excessive in case of the more readily available forms, such as superphosphate and Thomas slag.

Do phosphatic and potassic fertilizers exert a direct influence upon cultivated plants? C. LUMIA (*Staz. Sper. Agr. Ital., 35 (1902), pp. 525-549; abs. in Chem. Centbl., 1902, II, No. 21, p. 1338*).—The author concludes from his investigations and observations that the mineral constituents of fertilizers exert a direct and favorable action on the micro-organisms of the soil, but have only an indirect effect on plants by furnishing conditions favorable to organisms which supply them with nitrogen compounds.

The returns from top-dressing with potash salts, BACHMANN (*Deut. Landw. Presse, 29 (1902), No. 97, pp. 785, 786*).—Experiments with kainit on barley, oats,

and fodder beets, and with 40 per cent potash salt on potatoes are reported. The results show that the best results with potash salts as top-dressing were obtained in case of winter grain, because the winter weather conditions were well suited to dissolve and distribute the salts in the soil. Potash salts should not be applied when the plants are moist with rain or dew, since they will adhere to and injure the leaves. The best results were obtained when the salts were applied in dry weather just before a rain.

On the potash fertilizing of barley and the replacement of potash by soda, P. DOLL (*Landw. Vers. Stat.*, 57 (1902), No. 5-6, pp. 471-476).—Pot experiments with barley are reported in which the effect of the sulphates and chlorids of potassium and sodium singly and combined in various ways were compared, the soil used being a mixture of one-third sandy field soil and two-thirds pure river sand. The chlorids of both potassium and sodium gave better results than the sulphates. This, it is stated, is due in the case of the potassium chlorid to the greater diffusibility, and in case of the sodium chlorid to its greater power of rendering the potash of the soil available. The applications of soda were only slightly less effective than those of potash, the best results being obtained with mixtures of the two. Analyses of the crop show that as a rule the increase in yield was accompanied by an increase in the proportion of potash or soda in the plant.

Report of work of the Ivanov Agricultural Experiment Station of P. I. Kharitonenko, Kharkov, 1901, J. M. ZHUKOV (*Rev. in Zhur. Opitn. Agron. [Jour. Expt. Landw.]*, 3 (1902), No. 1, pp. 69-76).—The report of the operations of this station contains an account of experiments with fertilizers—superphosphates, Thomas slag, untreated mineral phosphates, lime sludge from purification of beet juices, and nitrate of soda—on chernozem soils. The effect of the nitrate in increasing the yield was found to depend very largely upon the progress of nitrification in the soil, and this in turn to a large extent upon the meteorological conditions. Thus in 1898 and 1899, when the available nitrogen in the soil was only 0.0018 per cent, the nitrate was beneficial, but in 1900, with an available nitrogen content of 0.003 to 0.004 per cent in the soil, it was not needed. When there was a sufficient quantity of available nitrogen already in the soil the addition of nitrate lowered the quality of beets. The lime sludge proved an effective fertilizer not only because of its lime content but on account of the nitrogen, phosphoric acid, and potash which it contains in considerable amounts. It was shown that superphosphate was beneficial even during drought and that its effect is not exhausted the first year.—P. FIREMAN.

Report on demonstration fertilizer experiments carried out in Lower Austria in 1901, O. REITMAIR (*Zschr. Landw. Versuchs. Oesterr.*, 5 (1902), No. 11, pp. 1289-1357, pl. 1).—The results of cooperative experiments on potatoes and beets are reported in detail and discussed. In these experiments fertilizers were distributed to 495 farmers, of whom 221 or 44.6 per cent returned reports which could be used. The fertilizers, containing 35 kg. of nitrogen in nitrate of soda, 49 kg. of phosphoric acid in Thomas slag or superphosphate, and 28 kg. of potash in 40 per cent potash salt per hectare, gave an average increase in yield of potatoes of 26 per cent and of beets 32 per cent.

On green manuring experiments in Pomerania, BAESSLER (*Mitt. Deut. Landw. Gesell.*, 17 (1902), No. 46, pp. 273-278).—Experiments with leguminous plants—lupines, serradella, etc.—on different kinds of soil extending over a number of years are briefly reported.

Directions for making local fertilizer experiments, K. HANSEN (*Vejledning ved Udførelsen af lokale Gødningsforsøg*. Copenhagen: O. C. Olsen & Co., 1902, pp. 35).—Brief directions are given for the use of farmers, with blank forms for keeping records.

The use of plaster in agriculture, L. GRANDEAU (*Jour. Agr. Prat.*, n. ser., 4 (1902), No. 52, p. 325).—Analyses of 5 samples of gypsum are reported and attention is called to the danger of adulteration.

Commercial fertilizers, E. H. JENKINS ET AL. (*Connecticut State Sta. Rpt. 1902*, pt. 1, pp. 104).—This includes a statement of fertilizer sales in Connecticut in 1902, the text and an abstract of the State laws relating to fertilizers, a list of manufacturers securing licenses under these laws, notes on the sampling and collecting of fertilizers, explanations regarding the analysis and the valuation of fertilizers, a review of the fertilizer market for the year ended October 31, 1902, and tabulated analyses and valuations of 396 samples of fertilizing materials, including nitrate of soda, sulphate of ammonia, dried blood, cotton-seed meal, castor pomace, dissolved boneblack, dissolved rock phosphate, carbonate of potash, sulphate of potash, double sulphate of potash and magnesia, muriate of potash, bone manures, slaughterhouse tankage, dry ground fish, bone and potash, nitrogenous superphosphates and guanos, tobacco stems, vegetable ashes, wood ashes, leached wood ashes, ashes of tobacco stalks, tobacco-stem ashes, cotton-hull ashes, stone lime, lime-kiln ashes, waste lime from gas manufacture, Mexican potash, garbage tankage, sheep manure, land plaster, and mixed fertilizers.

Fertilizer inspection, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul. 85*, pp. 153-168).—This bulletin contains the analyses of samples collected by a representative of the station during 1902. A previous bulletin (E. S. R., 13, p. 1031) gave the results of analyses of samples furnished by the manufacturers. "A comparison of the results of the analyses of the samples collected by the station with the percentages guaranteed by the manufacturers shows that, as a rule, the fertilizers sold in the State are well up to the guarantee," although considerable variation in different samples of the same brands was observed in several cases.

Analyses of commercial fertilizers and manurial substances, C. A. GOESSMANN (*Massachusetts Sta. Bul. 84*, pp. 30).—Analyses are reported of 253 samples of fertilizers collected in the course of regular fertilizer inspection during 1902, and of 59 samples of fertilizing materials sent to the station for examination, including wood ashes, hemp ashes, waste ashes, tan-bark ashes, brick-yard ashes, burned bone, ground bone, nitrate of soda, dissolved boneblack, muriate of potash, low-grade sulphate of potash, sulphate of ammonia, green celery stalk and leaf, manure, mold, wool waste, sizing paste, lime, fiber waste, horn dust, tankage, complete fertilizers, and soils.

Composition and value of waste materials of the farm, orchard, and vineyard, G. E. COLBY (*California Sta. Rpt. 1899-1901*, pt. 2, pp. 259-262).—Analyses are reported of grape pomace, commercial fertilizers, gypsum, citrus-fruit culls, refuse prunes and olives, and other waste materials. Notes are given on the value of the different materials. It is stated that citrus-fruit culls and grape pomace should be composted with fresh unslaked lime or lime refuse from beet-sugar factories in order to correct acidity before applying as a fertilizer. Olive refuse and pomace on account of their fat content act slowly as fertilizers. Materials containing large quantities of common salt can not safely be used on certain crops, notably tobacco.

Use of commercial fertilizers, G. M. TUCKER (*Missouri State Bd. Agr. Mo. Bul.*, 2 (1902), No. 7, pp. 4-6).—A brief discussion of general principles.

Fraud in phosphatic slags, MAIZIÈRES (*L'Engrais*, 17 (1902), Nos. 47, pp. 1119, 1120; 50, pp. 1191, 1192).—Attention is called to the use of ground rock phosphate as an adulterant of slag.

The phosphate industry in 1902, C. C. SCHNATTERBECK (*Tradesman*, 48 (1903), No. 10, pp. 83-85).—In this article, quoted from the *Engineering and Mining Journal*, consolidation of phosphate mining enterprises is stated to have been a leading feature of the year. The total output during the year is reported as 1,580,997 long tons, an increase of about 5 per cent over that of 1901. As regards consumption the phosphate was about equally divided between Germany, Belgium, and England on the one hand and the southern United States on the other. The shipments of phosphates in 1902 were somewhat over 9 per cent greater than in 1901. Of the phos-

phates mined in 1902 Florida furnished 839,345 long tons, Tennessee 429,902 tons, South Carolina 285,625 tons, North Carolina 25,000 tons, Pennsylvania 875 tons, The occurrence of phosphate deposits in Arkansas, Georgia, Texas, New Mexico, Missouri, and Alabama, and the discovery and exploitation of new deposits in Africa, Australia, New Zealand, Algeria, Tunis, and Christmas, Ocean, Swan, and Marcus islands are noted.

FIELD CROPS.

Report of the North Louisiana Experiment Station for 1901, D. N. BARROW (*Louisiana Stat. Bul.* 71, 2. ser., pp. 930-953).—This report presents the work of the station for 1901, which included rotation and irrigation experiments and variety, fertilizer, and culture tests with different field crops.

Among 36 varieties of corn Virginia White Dent and Gandy gave the most profitable returns. Champion Yellow Dent and Red Driver yielded more grain than Gandy but were less profitable on account of the smaller yield of stover. Six sweet corn varieties were tested and of these Stowell Evergreen and Country Gentleman produced the largest yields of grain and stover. Mexican June corn, planted June 3, yielded 20 bu. per acre of very good corn. The cost of cutting and shredding stover is estimated at \$1.50 per ton. The composition of corn stover, timothy hay, and Johnson grass is given.

In the variety tests with wheat Fultz led with a yield of 28 bu. per acre, followed by Red May with 27 bu. and Harvest King with 26.2 bu. All varieties were harvested the last week of May. Wheat is considered the best winter grazing crop for that region.

Of 20 varieties of cotton under test Hagerman produced the highest yield of seed cotton, 1,680 lbs. per acre. This variety was followed by Boyd Prolific and Peerless with a yield of 1,575 lbs. each. Peterkin Improved gave 31.5 per cent of lint, which was the highest percentage produced. Fertilizer tests with cotton were inconclusive.

The results in rotation and irrigation tests were largely in favor of the plats under rotation and irrigation. The quantity of water in inches required to mature the different crops in 1901 was as follows: Sugar cane 29.40, cotton 18.70, cowpeas 18.70, corn 18.16, sorghum 15.63, tobacco 11.87, and watermelons 11.06. The analyses of sugar cane showed that irrigation not only increased the tonnage but the sugar content as well.

The following leguminous crops were tested: Cowpeas, velvet beans, peanuts, clover, and alfalfa. Yields of 3,234 lbs. of crimson and 3,732 lbs. of red clover hay were obtained per acre. Alfalfa yielded a total of 2.2 tons per acre. Spanish peanuts yielding 4,410 lbs. of hay with the nuts attached were more profitable than Virginia peanuts.

Three varieties of pumpkins, Large Cheese, Kentucky Field, and Cashaw or Crook Neck, yielded 7,168, 6,865 and 4,280 lbs. per acre, respectively.

Notes are given on the culture of rescue grass, redtop, rape, and tobacco. The work of the station with swine, sheep, and poultry is briefly described.

Fixation of atmospheric nitrogen by alfalfa on ordinary prairie soil under various treatments, C. G. HOPKINS (*Jour. Amer. Chem. Soc.*, 24 (1902), No. 12, pp. 1155-1170, pls. 2).—More fully reported in Bulletin 76 of the Illinois Station (E. S. R., 14, p. 563).

Experiments with barley, REMY (*Deut. Landw. Presse*, 29 (1902), Nos. 87, p. 706, fig. 1; 88, pp. 715, 716).—Breeding experiments were conducted to originate plants adapted to dry localities, and the results obtained and the conclusions drawn are here presented. The measurements and weights of the different parts of the plant for each season from 1900 to 1902, inclusive, are given in tables. Two strains of Hanna and Goldthorpe barley differing in moisture requirements have been obtained and

have been grown in comparison. In each case the plants with the low moisture requirements produced the larger percentage of grain. The strains requiring but little moisture were shorter in the straw and also shorter and closer in the head than those which required the greater quantity of water. The quality for brewing purposes in the new strains was not changed because the protein content of the grain and the percentage of glumes to the grain did not enter into the basis upon which the improvement by breeding was carried on. The author discusses the means other than plant breeding by which plants may be successfully grown in dry localities and further points out how by breeding the period during which the plant uses the greatest amount of moisture can be moved toward the winter season and thus the supply of winter moisture be made to benefit the growing plant.

The fertilizer experiments conducted for several years have shown that an increase in yield due to applications of phosphoric acid is accompanied, as in the case of potash, by a proportional decrease in protein content. On the other hand, phosphoric acid did not affect the size of the grain which is so characteristic of potash. The use of phosphoric acid further caused a uniform and rapid development of the young plants. Owing to the rather rapid growth of the plant readily soluble phosphates are required.

Berseem, D. G. FAIRCHILD (*U. S. Dept. Agr., Bureau of Plant Industry Bul. 23, pp. 20, pls. 14*).—This bulletin gives a historical account of the culture in Egypt of berseem (*Trifolium alexandrinum*), also called Alexandrian and Egyptian clover, and describes its general uses. Three distinct varieties grown in Egypt are discussed. *Muscovi* berseem, the variety commonly grown under irrigation in the delta, is the most important. It is stated that this variety planted in early autumn will give 4 cuttings, the first 2 yielding about 8 tons per acre of green forage each, and the last 2 about 6 tons each. When seed is required the plants are allowed to go to seed in June after the fourth cutting. The yield of seed is reported as much heavier than that of clover. An instance is mentioned where berseem planted January 5 was cut March 11, April 7, and April 30, and the roots then plowed under. In an experiment carried on in Algeria berseem sown July 26 yielded a total of 42 tons of green fodder per acre in 3 cuttings, the first one being made September 12. The usual Egyptian yield for 4 cuttings is about 28 tons. In connection with this discussion the records of temperature and relative humidity for June, July, and October of an average Egyptian season, and a comparison of chemical analyses of green berseem and alfalfa in Egypt, are shown in tables.

"*Fachl* berseem is a variety used in Egypt on land which is irrigated by the basin system—i. e., overflowed for 40 days in the autumn months from August until November, depending on the latitude and Nile overflow. Saida is the name of a variety of berseem which, although yielding less than *Muscovi*, is relatively more nutritious. It possesses a comparatively long tap root which enables it to thrive with much less water than is required for *Muscovi*, and it is, in fact, considered a kind of dry land berseem. It is sown in the basins but requires subsequent irrigation, as it yields 2 cuttings."

The value of berseem as a green fodder and hay crop and its probable adaptability to certain sections in this country are considered.

Experiments with white clover, P. P. DEHÉRAIN and E. DEMOUSSY (*Ann. Agron., 28 (1902), No. 10, pp. 497-522, figs. 3*).—Inoculation, fertilizer, and rotation experiments carried on for several years are reported. The inoculation tests were made in pots with 4 soils from as many different localities. On only one soil did the inoculation with garden soil, containing the proper bacteria for clover, show effect. This soil, a sort of leaf mold, contained the necessary bacteria but they were present in insufficient numbers to be effective. The results also showed that lime on noncalcareous soil is of value in this connection when applied together with superphosphate or a soluble phosphate. Lime alone, or applied with a phosphate in nodular form,

proved detrimental. Phosphates in nodular form were only slightly effective and inferior in this respect to Thomas slag. On one of the soils potash salts proved beneficial to the growth of the clover. As has been often observed, clover after clover or alfalfa did not make a very good growth.

Varieties of white clover, C. FRUWIRTH (*Fühling's Landw. Ztg.*, 51 (1902), No. 24, pp. 877-882).—The results of tests with Italian, Colossal Ladino, Solemacher, and common German white clover carried on for several years are reported. The yields are given, together with measurements of the leaf and stem of the different varieties. The seed of the common German variety was larger and heavier than the seed of any of the other varieties. As compared with the common German the other varieties made a more luxuriant growth, blossomed later and less profusely, and produced larger quantities of green and air-dry substance and also of dry matter and protein. These 3 varieties grew satisfactorily on sand and clay soils and were equally hardy with the common German. The author found no perceptible difference between these varieties, and regards all as belonging to the same form.

Manual of corn judging, A. D. SHAMEL (*Urbana, Ill.: Author, 1902*, pp. 36, figs. 12).—The purpose of this manual is to assist and guide in the more systematic study of the ear of corn. Among other points attention is given to standards of perfection, variety measurements, the score card and its use, the study of characteristics, and the handling and testing of seed corn.

Analyses of hop cones and hop vines, G. E. COLBY (*California Sta. Rpt. 1899-1901*, pt. 2, pp. 252-254).—Analyses of the ashes of hop cones, the ingredients of hop ashes, the soil ingredients extracted by hop cones and hop vines, and analyses of the soils of hop fields are tabulated.

Experiments with yellow lupines, P. P. DEHÉRAIN and E. DEMOUSSY (*Ann. Agron.*, 28 (1902) No. 9, pp. 449-482, figs. 2).—Observations on the growth and culture of yellow lupines during 6 years are reported. When grown in sand destitute of humus, yellow lupines, although given commercial fertilizers and lime, either made no growth or grew very poorly. Humus added to the soil under these conditions enabled the plants to grow and flower and even to ripen their seed without the presence of nodules on their roots. These plants grew without utilizing the nitrogen of the air, but using the combined nitrogen in the soil just as is done by nonleguminous plants. Inoculating the roots with extracts from the nodules of alfalfa, hairy vetch, and furze showed no effect. The lupines grew and produced nodules in leaf mold which had received commercial fertilizers, but a better growth was obtained in soil consisting of sand with an addition of 10 per cent of leaf mold. An addition of lime to the leaf mold caused a rapid destruction of the plants, and even in a good friable, calcareous soil, although well supplied with barnyard manure, the plants did not live. In a test with a noncalcareous soil the lupines grew fairly well when commercial fertilizers were used, and in this case the phosphates gave particularly good results, phosphate of potash and Thomas slag being the most effective. In this soil the roots were found well covered with nodules. In another test with a strong soil low in calcareous matter and obtained from a different locality, the upper portions of the roots were very densely covered with nodules. From these results the conclusion is drawn that the activity of the bacteria causing the nodules differs with the soil. At Grignon yellow lupines on a good but rather light soil containing 4 per cent of lime made a fair growth and ripened their seed, but no nodules were produced on the roots. Inoculating soil at Grignon with soils in which the plants were provided with nodules did not give very good results.

Variety tests of oats and potatoes, G. C. WATSON and E. H. HESS (*Pennsylvania Sta. Rpt. 1901*, pp. 223-234).—The results of tests with oats and potatoes by the station are summarized and the methods of carrying on the work are described.

Oats.—Of 19 varieties tested in 1900 the most productive were Sensation, Irish Victor, Silver Mine, Henderson Clydesdale, and Heavy Weight Champion, yielding

45.69, 44.94, 42.65, 42.56, and 42.53 bu. per acre, respectively. The average yield of all varieties was 38.52 bu. of grain and 2,305 lbs. of straw per acre. Tables are given showing the average yield of varieties for 9, 4, 3, and 2 years. Among the varieties tested for 9 years Japan gave a slightly better yield of grain than the other varieties and as large a yield of straw. The average weight of grain per bushel for this variety was 36 lbs., but the results show that the weight of the grain per bushel and the yield had little or no connection.

Potatoes.—A test of 95 varieties was made in 1900. The yields obtained ranged from 48.23 to 188.68 bu. per acre and the time of ripening from August 18 to October 12. Heath Late Beauty was the most productive, and Polaris, Six Weeks, Early Andes, and New Bovee Seedling the earliest. Tables are given showing the average yield of the varieties tested 6, 5, 4, 3, and 2 years. Of the varieties tested 6 years Carman No. 1 gave the largest total and merchantable yield. The average yields of the most productive varieties of those tested 6 years were over 16 per cent greater and of the varieties tested 5 years over 45 per cent greater than the yields of the sorts producing the smallest quantities of merchantable tubers.

Saltbushes in the Southern Coast Range, C. H. SHINN (*California Sta. Rpt. 1899-1901, pt. 2, pp. 334-345, figs. 4*).—The work with saltbushes by the station is reviewed and recent results with new species are reported. The value of *Atriplex semibaccata* is pointed out in the results obtained by the station and by farmers in the State. A number of species tested at the Paso Robles substation have given good results, and in this connection special attention is called to the following: *Atriplex nummularia*, *A. pamparum*, *A. cuneata*, *Rhus glabra*, and *R. spinescens inermis*. *Atriplex leptocarpa* had no advantages over *A. semibaccata* in that region, and *A. vesicaria* and *A. halimoides* exhibited a tendency to die out in spots when the plants are old. *A. nummularia*, grown from cuttings and without irrigation, gave a yield of 17 tons 485 lbs. of green forage per acre from one cutting. *A. pamparum* and *A. cuneata* yielded over 15 and 12 tons of green forage per acre, respectively. These 3 saltbushes are large-growing species and produce 2 cuttings a year in that locality. Brief descriptive and cultural notes are given on *R. spinescens inermis*, *R. glabra*, *R. billardieri*, *R. parvifolia*, *R. hastata*, *Chenopodium nitrosum*, and *C. atropurpureum*. Directions for the propagation of saltbushes from cuttings and other suggestions as to their culture are also given.

Analyses of sugar beets, M. E. JAFFA (*California Sta. Rpt. 1899-1901, pt. 2, pp. 237-241*).—Analyses of samples of sugar beets from 1898 to 1900 are given in tables and the results are briefly discussed.

The beet-sugar industry in Victoria, A. N. PEARSON (*Melbourne: Robt. S. Brain, Govt. Printer, 1901, pp. 37, pls. 5, fig. 1, dgm. 1*).—This is a paper on the subject published in 1901. The results of experiments with sugar beets in Victoria, including culture, variety, and fertilizer tests, are brought together and the possibilities of the industry are discussed.

Note on the localization of phosphates in the sugar cane, C. H. G. SPRANKLING (*Jour. Chem. Soc. [London], 81 (1902), No. 481, I, pp. 1543-1546*).—Determinations of phosphoric acid and silica in the leaves and in different sections of the stalk of sugar cane are reported. These show that the largest percentage of phosphoric acid was in the leaves, the smallest in the middle sections of the stalk, increasing toward the roots. There appears to be a storage of phosphoric acid as well as silica in the leaves.

Seedling and other canes in the Leeward Islands, 1901-2 (*Imp. Dept. Agr. West Indies, Pamphlet No. 20, 1902, pp. 30*).—This report summarizes the results of experiments with sugar cane carried on at Antigua and St. Kitts-Nevis in 1901-2.

Seedling and other canes at Barbados, 1902 (*Imp. Dept. Agr. West Indies, Pamphlet No. 19, 1902, pp. 67*).—This report summarizes the results of cooperative experiments with selected seedling and other canes. As in previous years, the canes

were cultivated on different estates and on black and red soils. A list of the different varieties, with their more general field characteristics and the more important cultural and chemical results, are given. Barbados Seedling 208 gave the best results, being followed by White Transparent. Barbados Seedling 147 and Sealy Seedling were low in quality of juice.

Report of the agricultural work for 1900-1902, J. P. D'ALBUQUERQUE and J. R. BOVELL (*Rpt. Agr. Work, Imp. Dept. Agr. West Indies, Rpt. 1900-1902, pp. 185*).—The results of fertilizer experiments and variety tests with sugar cane are tabulated in detail, and briefly discussed for each experiment and locality. In addition, the mechanical and chemical analyses of the soil and the rainfall for the different localities in which the work was carried on are given. Experiments with seedling and other varieties of cane are reported, together with descriptions of their general characteristics, yield, and composition.

The origin of starch in the wheat grain, P. P. DEHÉRAIN and C. DUPONT (*Ann. Agron., 28 (1902), No. 10, pp. 522-527*).—This article discusses the formation of nitrogenous substance in the wheat plant and reports the results of experiments conducted to throw further light upon the formation and accumulation of starch in the grain. The authors point out how the nitrogenous substance in the plant rises from the lower to the upper leaves and finally finds its way into the grain, while during the entire vegetative period no starch gathers in the leaves of wheat as is done in the leaves of the potato, tobacco, the vine, and other plants, and still starch accumulates rapidly in the grains shortly before ripening. It is held that since wheat has no reserves of carbohydrates the starch of the grain must be elaborated from new material, but that the difficulty which presents itself in this connection is the small percentage of green leaf surface, which at this stage is practically confined to the glumes and the upper parts of the stems. An investigation to determine whether these organs at that time are capable of using the carbonic acid of the air and forming carbohydrates showed the incapability of the glumes in this respect.

In order to determine the action of the upper portion of the stems, the heads were removed from a number of plants which were then harvested the next day together with an equal number of entire plants. In both cases the stems only were analyzed and the results showed that the quantity of carbohydrates elaborated in the stems without heads was equal to 5.94 per cent of the dry matter, while in the stems on which the heads were allowed to remain only 1.63 per cent was found. This difference is explained as due to the movement of the carbohydrate substance into the grains, and the results are considered as indicating conclusively that the upper portion of the stem, provided it is still green, performs the function of the leaves in other plants and thus elaborates the starch for the wheat grain. Attention is called to certain seasons in which the conditions of the weather and the resulting yield and composition of the grain go to confirm the above conclusion. The harvest of 1888 at Grignon was late and the process of ripening slow, which resulted in a heavy yield with an average gluten content in the grain of 12.60 per cent and a starch content of 77.2 per cent, while the following season, when the summer was hot and the process of ripening rapid, the grain contained 15.3 per cent of gluten and only 61.9 per cent of starch.

HORTICULTURE.

Specific variation in the graft or asexual hybridization, L. DANIEL (*Troisième Congrès International de Défense contre la Grêle et de l'Hybridation de la Vigne. Lyons: Soc. Rég. Vit., 1902, II, pp. 262-265*).—Ancient and modern ideas regarding the existence of variation in grafts are reviewed at length, the author's methods of grafting and carrying on control work discussed, and detailed accounts given of specific variations obtained in scion and stock in grafting a large number of different

kinds of plants involving many different families. Illustrations of the results obtained are given in some instances. A bibliography of the works of 67 authors on various phases of grafting is appended.

Formerly it was believed that grafted scions lost none of their own characteristics and acquired no new ones from the stocks on which they were grafted. Recent experiments indicate that these views must be modified. The author notes that a student of his grafted by approach *La France*, a very double rose, with *Panachée d'Orleans* a semidouble rose. As a result, the roses grown on the grafted branch of *La France* were semidouble, while on all the other branches of *La France* only the very double roses appeared. The author grafted a large red tomato on an eggplant having long violet fruits. The resulting tomatoes changed their shape entirely and took on an elongated form like that of the eggplant fruit. The converse graft produced 3 kinds of fruit—long, smooth, and slightly pyriform like the normal; smooth, ovoid fruits, and fruits slightly flattened like the tomatoes. The *Bergamotte Espéren* variety of pears, which has a rounded form, became more elongated after grafting on the *Curé*, a variety having a fusiform shape. Entirely new varieties produced by grafting are also noted. The *Sylphide* rose budded on *Homère* produced stems with less thorns than either parent, leaves intermediate in size between the two, and blooms intermediate in size and color. Like results with other varieties of roses are also noted. The flavor of Belgian Kidney beans was considerably modified by grafting on another vigorous growing variety (*Haricot de Soissons*). A number of variations in stem, pith, etc., occurred when *Helianthus latiflorus* was grafted on Jerusalem artichoke (*H. tuberosus*) and common sunflower (*H. annuus*). Hedge mustard (*Alliaria officinalis*) when grafted on cabbage lost much of its characteristic odor. Cabbage having an elongated conical head when grafted on a variety having a flattened round head in some instances took the form of the latter. When privet (*Ligustrum ovalifolium*), with persistent leaves, was grafted on the lilac it regularly thereafter shed its leaves in the fall like the lilac. The foxy taste of certain American grapes has been eliminated by grafting on vines not showing this characteristic.

The author shows that hybrids produced by grafting can be fixed and propagated true to kind. Thus the variety of potato *Edouard Lefort*, produced by grafting together *Marjolin* and *Imperator*, and partaking of the character of each, reproduces itself true to kind. A hardy and improved variety of forage cabbage was secured by grafting a rather tender sort of kohlrabi on a very hardy form of head cabbage. The hybrid form produced was more hardy, more resistant to disease, and a better forage plant than either parent, and had a form somewhat intermediate between the two. These characters were transmitted through the seed and became permanent thereafter from seed. Variations in tomatoes obtained by grafting have been more or less completely preserved in the seed.

Other interesting results, showing the variations obtained in grafting wild and cultivated carrots, various beans, peppers, eggplants, etc., are also recorded.

From the experiments and observations cited the author draws the conclusion that asexual hybridization is neither constant, nor regular, nor very frequent. In its results it is somewhat similar to cross pollination, but has a wider application, and the resulting forms obtained are less constant in character. Grafting is not always a certain means of perpetuating variations, although it generally is. Grafting itself may occasion variation which in turn can be fixed by grafting.

In order to produce a given variation by grafting or to add to a plant a character which it lacks, it is necessary to graft it on another plant which is superior to it in the quality sought. Thus in the case of the forage cabbage mentioned above, hardness was obtained in a variety of kohlrabi by grafting it on one of the hardest forms of head cabbage. In grafting hybrid vines to secure a desired character, it is necessary to graft together 2 vines having common blood in such proportions that

the sum of the blood of the characters desired shall be greater than the blood of any other strain in the graft. Thus, if with a sexual hybrid possessing $\frac{2}{3}$ blood A, $\frac{1}{3}$ blood B, and $\frac{1}{3}$ blood C, a character K of the A blood, which is in the minority, is desired, it is likely to be obtained by grafting it on another sexual hybrid having, for example, $\frac{1}{2}$ blood A, $\frac{1}{3}$ blood B, and $\frac{1}{6}$ blood C. The total blood then which will unite to form the new hybrid will be made up of the sum of these or $\frac{5}{6}$ A blood, $\frac{2}{3}$ B blood, and $\frac{1}{6}$ C blood, in which it is seen that the A blood predominates and the character K is likely to appear. Modifications in vines as regards eradication of the foxy flavor, increase in size of berry, resistance to exterior agents, etc., can thus be obtained.

The author states that the problem of the grape industry in France is to unite the resistance of American roots to the quality of French grapes. This will probably be done not by sexual hybridization alone but by sexual hybridization combined rationally with asexual hybridization by the graft and the preservation of the variation thus obtained by budding.

Curious results obtained in grafting, L. DANIEL (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 12, pp. 481, 482; *abs. in Rev. Hort. [Paris]*, 74 (1902), No. 20, pp. 470, 471).—An account is given of some recent work in grafting *Scopolia carniolica* on tomatoes. *S. carniolica* is a perennial herbaceous plant, and one of the first to appear in spring. After fructification its aerial stems remain green for a short time, then gradually wither, and finally entirely dry up during the month of May. Scions of *S. carniolica* were taken after fruiting, and when the stems had begun to wither, and grafted on growing tomatoes. The graft succeeded, producing new buds and leaves, and one branch gave 3 normal flowers. The success of this graft led to the conclusion that similarity of habit of stock and scion is not an absolute condition of success in grafting.

Specific variations in the graft, G. T. GRIGNAN (*Rev. Hort. [Paris]*, 74 (1902), No. 17, pp. 414-416).—This is an abstract of L. Daniel's work noted above.

Specific variations caused by grafting (*Gard. Chron.*, 3. ser., 32 (1902), No. 832, pp. 409, 410).—Review of the work of Daniel and Lindemuth along this line.

Electroculture. Increase in the yield of cultivated crops obtained by electrical treatment, S. LEMSTRÖM (*Elektrokultur. Erhöhung der Ernte-Erträge aller Kultur-Pflanzen durch elektrische Behandlung. Berlin: R. Friedländer & Son, 1902, pp. IV+ 43, figs. 4*).—An abstract of a part of this work has been previously made from current periodicals (*E. S. R.*, 14, p. 352). The pamphlet contains much detailed data in addition to that already noted, including a general description of the electrical machine used. In laboratory experiments it was found that if a capillary tube is placed in a vessel of water which is in electrical connection with the earth, and a fine metal point connected with the negative pole of an electrical machine be suspended over the upper end of the tube, small drops of water soon collect in the upper part of the tube after the machine has been set in motion. This result is believed to throw light on the increased growth of plants subject to electrical currents. Thus when a metal net connected with the negative pole of an electrical machine is suspended above growing plants a more energetic rise of sap containing plant food takes place in the plant and growth is therefore more rapid.

The author's experiments on the whole, with both field and garden crops, show an average increase in growth of 45 per cent due to the use of electric currents. The electrical treatment was most influential in well-tilled fields. On poor soils no noteworthy results were attained. Some plants must be well watered in order to obtain the maximum effect of the electricity. Peas, carrots, and cabbage belong to this class. Electro-culture combined with strong sunlight proved harmful for most plants. It is therefore considered advisable that during the hot, sunny portions of the day the electrical current be stopped.

Growing vegetables under cloth (*Amer. Agr.*, 70 (1902), No. 22, pp. 595, 596).—The success obtained in the culture of tobacco under shade in Connecticut and Florida has led various experimenters to try the growing of vegetables under

like conditions. The results obtained by some of the growers have been brought together in the present article. F. Bunce, of Hartford, Conn., reports that cucumbers, watermelons, and muskmelons grown under shade were not a success. The vines grew well, but the fruits were small. In the case of cucumbers a few reached small pickling size. The melons did not do as well. He states that strawberries, however, on Long Island were 2 weeks earlier under cloth than out of doors, while wild dandelion just inside the tent made an enormous growth.

C. F. Dane, of Hartford, Conn., a tobacco grower, reports that cucumber, watermelon, and tomato vines grew better in the tent than outside, but yielded hardly any fruit, and the little that set shriveled up.

L. W. Ripley, of the same place, grew muskmelons and cucumbers under cloth, but found no advantage in the practice over outdoor culture. The tent shelter did not protect the vines from mildew or blight. Little difference was found by Mr. Ripley in the temperature inside and outside the tent. The general opinion of the experimenters appears to be that nothing is gained in vegetable culture by growing the plants under cloth.

Sewage and night soil or stable manure and commercial fertilizers for vegetables, J. P. WAGNER (*Deut. Landw. Presse*, 29 (1902), Nos. 64, pp. 529, 530; 65, pp. 537-539, figs. 4).—A presentation of some of the objections to the use of sewage and night soil in the culture of vegetables and fruits eaten raw, like lettuce, water cress, radishes, strawberries, etc., with summaries of a number of experiments showing the value of stable manure when supplemented with commercial fertilizers for these crops. The author states that not only is there a natural aversion to the use of such materials as night soil and sewage for growing vegetables to be consumed raw, but, on the authority of Würtz and Bourges, their use is positively dangerous. Recent experiments by these French bacteriologists are cited to show that diseased germs are carried in such material and may be taken up and preserved in the tissues of vegetables. In one instance water cress, head lettuce, and radish seed were sown in pots and the soil watered with diluted sputum that had been saved up for 40 days from a tuberculous patient. After a certain period pieces of the leaves of the vegetables grown were used to inoculate guinea pigs. As a result, 18 of the 30 inoculated pigs developed tuberculosis. Like experiments were also made with typhoid fever bacilli, and in every case, without exception, the typhoid bacillus was easily found in the leaves of the vegetables.

The chief purpose of the article is to show that better and cheaper vegetable crops can be grown by the rational use of commercial fertilizers, supplemented by stable manure, than with city sewage, and the former is less dangerous to health.

List of American varieties of vegetables for the years 1901 and 1902, W. W. TRACY, JR. (*U. S. Dept. Agr., Bureau of Plant Industry Bul.* 21, pp. 402).—All the varieties of garden vegetables, including field corn and herbs, but omitting potatoes and sweet potatoes, catalogued during the years 1901 and 1902 by 245 seed firms in the United States and Canada, have been arranged alphabetically under the different vegetables. The seed firms handling each vegetable are noted, and the synonyms of the different varieties given. The catalogue is intended primarily to serve the purposes of seedsmen and experimenters. It is hoped also that it may serve as a basis for shortening and simplifying our present long and complex list of varieties of vegetables and to prevent the duplication of old names.

The fog fruit or *Lippia nodiflora* as an economic plant, J. J. THORNER (*Arizona Sta. Bul.* 45, pp. 234-238, figs. 2).—This plant is stated to be a perennial, herbaceous, much branched, creeping plant, the stems of which root extensively at the node. In a lawn it gives the effect of white clover, though forming a more compact mass and not requiring the use of a lawn mower. Observations at the station indicate that it can maintain a continuous layer of green with a less amount of water than any other desirable plant within the Territory. It is sensitive to alkaline salts,

and when these were applied at the rate of 1,700 lbs. to the acre the plants stopped flowering, turned a yellowish color, and began to die. When the salts were increased to 5,000 lbs. per acre, 95 per cent of the leaves died. It was stated that the ground upon which these experiments were conducted was already somewhat alkaline, so much so that roses would not flourish on it from year to year. Grazing animals appear to dislike the plant. Its chief value is as a sand and soil binder and as an ornamental in the lawn. When the plants were set 2 ft. apart each way in favorable situations, they completely covered the surface in one season's growth. It is thought to have especial value for planting along reservoirs and storm water embankments to bind the soil and prevent washing. Thus far it has not been observed to produce fertile seed in Arizona. In shaded lawns the plants tend to grow tall, lose their carpet-like formation, and seldom blossom. The plant is recommended for planting among rocks when it is desirable to hide them from view. It is usually propagated by cutting up the stems into 2-in. lengths and sowing them in drills during the spring or summer months. The station had more success in using rooted plants set about a foot apart in the row. The plants must be frequently watered until they have secured a permanent hold.

Ginger, G. LANDES (*Jour. Agr. Trop.*, 2 (1902), No. 13, pp. 203-207; *trans. in Queensland Agr. Jour.*, 11 (1902), No. 5, pp. 354-356).—A detailed discussion is given of the culture of ginger in tropical countries and its preparation for the market.

Propagation of the mango, G. W. OLIVER (*Florists' Exchange*, 14 (1902), No. 16, p. 461, figs. 2).—As the result of some experimental work in the grafting of mangoes the author states that the best time for grafting is when the new leaves are not far enough developed to show a bright green color. At this time the bark is most easily removed. The thick part of the stem a few inches above the ground should be chosen and a rectangular piece of bark about 1½ in. in length cut out. Another piece of bark taken from the variety which it is wished to propagate should be cut to a corresponding size and have a bud in its center. The scion bark should be taken from wood at least 2 years old. After the bark has been fitted in place a light coating of liquid grafting wax in which there is a large quantity of resin should be applied to the cut parts with a small brush, after which the bark should be immediately tied firmly in place with thick pieces of raffia. An 8-in. wide strip of strong wrapping paper is wound around the stem a few inches above the bud, extending downward to protect it, and tied with a cord. The author states that by this method a large percentage of successful unions may be expected.

The culture of onions in Holland, A. PION (*Jour. Agr. Prat.*, n. ser., 4 (1902), No. 51, pp. 802, 803).—A descriptive account of the onion industry of Holland. Silver skin onions are chiefly grown and the work is done mostly on a small scale by farmers and their families.

Peas put to the test, E. S. BROWN (*Amer. Gard.*, 24 (1903), No. 420, p. 22, fig. 1).—The tests with peas at the American Gardening trial grounds lead the author to recommend Surprise and Gradus for early, Gregory Surprise for second early, and Champion of England for third early. If only one pea could be grown the author would choose Surprise.

Manurial experiments with peas (*Gard. Chron.*, 3. ser., 32 (1902), No. 831, p. 391; *abs. in Amer. Gard.*, 23 (1902), No. 418, p. 833).—An increase in yield of 66½ per cent was obtained with the Daniel Best of All peas by dressing them with superphosphate and sulphate of potash at the rate of 3 lbs. of each spaded into 2 sq. rods of soil about 3 weeks before planting.

Cultivation of pepper, V. SEBASTIAN (*Queensland Agr. Jour.*, 11 (1902), No. 5, pp. 356-358).—Methods of cultivation and harvesting the pepper plant (*Piper nigrum*) are given.

Forcing tomatoes, A. C. BEAL (*Illinois Sta. Bul.* 81, pp. 503-524, figs. 5, dgms. 2).—The manner of forcing tomatoes in winter and the yield obtained with several varie

ties at the station are recorded. The author states that many tomato growers do not secure their first ripe fruits in the forcing house until 90 or 100 days after benching, when only about half this time is necessary. In one of the experiments seed of Combination and Yellow Prince varieties were sown in moderately rich soil October 23. They were potted in 2½-in. pots in a fibrous potting soil as soon as large enough, and shifted to 3½-in. pots about December 1. January 9 they were benching. At this time they were all showing open blossoms and were very much pot-bound. "The open blossoms set fruit and the plants continued to blossom at every third or fourth joint. Unchecked plants come into bearing later, as it takes time to fill the soil with roots and thereby check the excessive growth. On such plants the first fruit appears high up on the plant when it should be near the ground with a continuous succession of clusters up the stem."

The bench soil used was made of one-half rich garden loam and one-half well rotted compost. It was light in texture and fertile. Wood ashes at the rate of 20 lbs. per 100 sq. ft. were applied twice after the plants were in full bearing. The soil in the bench was 6 in. deep. The plants were set 2 ft. apart in rows 18 to 20 in. apart. The temperature of the forcing house varied from 70° F. at night to 75 to 80° on cloudy days and as high as 90° on sunny days. The plants were trained to single stems, using binder twine as a support. The leaders were pinched when the plants on the side benches had reached a height of 5 ft. and those in the center benches 8 ft. Shoots pushing out from fruit clusters, as is common in rapidly growing plants, were promptly removed. Hand pollination was practiced every other day when the pollen could be secured.

The first ripe fruits from Yellow Prince were secured February 25, or 47 days after benching, and from Combination February 28, or 50 days after benching. The average yield of Yellow Prince to June 11 was 2.85 lbs. per plant. There were about 16 fruits per plant, and they averaged in size 2.84 oz. The fruit of this variety was very uneven in size. There was no marked demand for the yellow sorts, and it is considered doubtful whether they are worth growing except a few plants for the sake of variety.

With the red variety Combination the yield on a north bench during the months March, April, and May averaged 4 lbs. per plant, or 17½ oz. per square foot of bench space. There were on an average 16½ fruits per plant, averaging 4.07 oz. in weight each. On a center bench set with this variety the yields during the months February to June averaged 8 lbs. per plant, or 2.4 lbs. per square foot of bench space. There was an average of 31 fruits per plant, weighing 4.1 oz. each.

Some of the plants in the above experiments received bottom heat, but the author states that the average size of the fruits and the yield were no greater with bottom heat than without it. During March the average weight of the fruit of Combination was 3½ oz., but with the increase in sunshine the average weight per fruit rose to over 4 oz.

During the winter of 1902 a test was made of 4 of the leading forcing varieties to ascertain their relative adaptation to winter forcing. Plants were sown August 20 and benching November 7. The first ripe fruit was picked December 24 from each of the varieties Combination, Lorillard, and Best of All. This was 47 days after benching. Eclipse did not ripen fruit until December 28 or 51 days after benching. The average total yields per plant for the different varieties were as follows: Combination, 4 lbs. 6 oz.; Lorillard, 4 lbs. 10 oz.; Best of All, 5 lbs., and Eclipse, 5 lbs. 4 oz. Best of All was the earliest and best of the 4 varieties as regards yield during the short, dull days of December, January, and February. Eclipse gave the largest total yield and produced the smoothest and most solid fruits.

Some data are given which show that fruits failed to set during long periods of cloudy weather because of the failure of the pollen to mature. This emphasizes the necessity of hand pollination whenever the sun does shine.

A spring crop was also grown in 1902. Seed was sown December 23, 1901, and the plants benched April 10. The first ripe fruits were obtained 52 days later. In addition to the above varieties, Stone and Roselind were also grown. With this crop Combination and Lorillard both yielded 3 lbs. of fruit per plant, Best of All 3 lbs. 6 oz., and Eclipse 3 lbs. 7 oz. The average yield per square foot for the 2 crops was about 2.37 lbs. When plants were trained to 3 stems a yield of 0.8 lb. per square foot was obtained, as compared with 1.25 lbs. for plants set the same day and trained to a single stem.

Aggregate atavic mutation of the tomato, C. A. WHITE (*Science*, n. ser., 17 (1903), No. 419, pp. 76-78).—The author notes that in one instance when seed of the Trophy tomato was planted in Habana, Cuba, the first crop produced tomatoes like the Trophy, but when seed from these was planted the resulting fruit was exactly like the small Cherry tomato. Similar results are reported from a parish in Louisiana, in which the seed grown in Louisiana produced the Cherry tomato instead of the much improved form from which the seed was obtained.

Edible native bulbs, E. BRAUNTON (*California Cult.*, 19 (1902), No. 26, p. 409).—The use of some native California bulbs, such as wild onions, several species of "Mariposa lilies," wild hyacinth, *Camassia leichtlinii*, and an introduced species of arrow root (*Sagittaria latifolia*), for food are noted.

Orchard studies. I. The fruit plantation. Pome fruits, W. B. ALWOOD (*Virginia Sta. Bul.* 128, pp. 73-102).—This is an alphabetically arranged catalogue of 416 varieties of apples, crab apples, pears, and quinces grown at the station during the past 14 years. "It has been carefully prepared to conform to correct nomenclature and spelling." It is stated that the station is prepared to furnish scions true to name, for purposes of study, etc., of such varieties as are in the orchard.

Climatic influences on the chemical composition of different varieties of apples in the autumn of 1900, as compared with the same sorts in the autumn of 1898, R. OTTO (*Landw. Jahrb.*, 31 (1902), No. 4, pp. 605-618).—In the fall of 1898 18 varieties of apples were analyzed with reference to their sugar, starch, and acid content, and the specific gravity of their musts. These same varieties were again analyzed in 1900. The variations in the 2 series of analyses are pointed out, and a study made of the relation of the differences to the precipitation and temperature during the two seasons—March to October, inclusive. During this period the average monthly precipitation in 1898 was 58.6 mm., while in 1900 it was 61.4 mm. As regards temperature, there was 281.7° C. more heat during the months of June, July, September, and October in 1900 than in 1898. Two-thirds of the varieties ripened considerably earlier in 1900 than in 1898, in many cases 2 weeks and in some cases 22 and 45 days earlier. The specific gravity of the musts of half of the varieties was considerably higher in 1900 than in 1898. In 13 out of the 18 varieties there was a considerable increase in the sugar content, and with 17 varieties a decrease in the acid content in 1900 as compared with 1898. The difference in rainfall and temperature in 1900 is believed to largely account for the earlier ripening and the differences in the chemical composition of the apples.

Astrakhans exported successfully (*Canad. Hort.*, 25 (1902), No. 10, p. 398).—A carload of Red Astrakhans was successfully sent to Glasgow. The carrier cases cost 22 cts. each and the freight and commission amounted to about 50 cts. per bushel. The fruit netted about \$435 at Grimsby, Ontario.

The book of pears and plums, E. BARTRUM (*London and New York: John Lane, 1903*, pp. 96, pls. 5, figs. 5).—This is the eleventh number of the series of Handbooks of Practical Gardening, edited by H. Roberts, and is similar in scope and purpose to the preceding books. In addition to the culture of pears and plums, that of cherries and mulberries is also taken up. Information is given on the cooking and preserving of pears, plums, and cherries. The culture of all these fruits is treated from the standpoint of European conditions.

Fruiting of the hardy orange (*Amer. Gard.*, 23 (1902), No. 416, pp. 797, 798).—It is reported that J. L. Normand, of Marksville, La., has succeeded in producing a hardy orange that will withstand a zero temperature. Ten years ago the hardy Trifoliata orange was crossed on the Satsuma variety of the sweet orange, for the purpose of securing hardiness combined with a palatable fruit. Some of the fruit obtained from this cross measured $6\frac{1}{2}$ in. in circumference. It had a globular form and bright yellow color, with a smooth, thin, and clean skin. The seeds were fewer than in the ordinary sweet orange and the quality was very fair. The tree is said to be prolific. The foliage is that of the Satsuma while the stems and branches have the thorns of the Trifoliata.

Comparative examination of shipping navel oranges from the northern, middle, and southern parts of the State, G. E. COLBY (*California Sta. Rpt. 1899-1901*, pt. 2, pp. 243-251).—This is a preliminary report on a systematic study of the progress of the maturing of navel oranges in the 3 citrus centers of the State of California. Analyses are reported of 5 samples of shipping navel oranges from the northern California citrus region, 7 from the San Joaquin Valley, and 16 from the southern citrus region. The averages of those packed during the month November 23 to December 23, compared with the standard for California navels, are shown in the following table:

Composition of California shipping navel oranges.

	Physical analysis.				Analysis of juice.			Flavor (30 points).
	Average weight.	Rind.	Flesh.		Total sol- ids (by spindle).	Total sugars.	Acid (cit- ric).	
			Pulp pressed.	Juice.				
	<i>Grams.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	
Northern region	240	27.4	24.2	48.4	10.00	7.37	0.94	18
San Joaquin Valley region ..	261	27.7	24.4	47.9	11.90	8.78	1.22	19
Southern region	184	29.5	25.4	45.1	11.80	8.77	1.43	19
Standard for California navels	288	28.4	30.0	41.6	13.30	10.46	.97	25

The quantity of sugar in oranges is believed to be a safe guide to the degree of ripeness of the fruit. The ratio of acid to sugar in standard California navels is 1 per cent of acid to 10.5 per cent of sugar. In the table above the proportion varies from 1:7 or nearly 8 in all the shipping navels of November and December. This fruit is roughly estimated to be about four-fifths ripe.

"It seems improbable that the shipping fruit of November and December would ever ripen enough in transit, or afterwards in the market, to bring up the sugar to that produced in the orchard in later-picked fruit, or to that of the standard. Our experience with keeping oranges over 2 months has been that the increase in sugar is very small—only $\frac{1}{3}$ of a point; e. g., from 10 to only 10.3 per cent total sugar."

In one instance a sample of oranges picked in the northern district December 5 contained 10.52 per cent of sugar. "This amount of sugar is only found in one other sample, the March 12 navel from Duarte, southern California region. Probably, as the northern orchards grow older, it will be more common for their earliest output to reach full maturity in early December. At any rate there seems to be a possibility of navels attaining very early full maturity in the northern citrus regions."

A table of analyses of shipping and fully ripe navels for the 3 citrus districts noted above for fruit picked between November 23 and March 12 is also included in the report.

Diagrams for packing citrus fruits, H. H. HUME (*Florida Sta. Bul. 63, folio, figs. 4, dgms. 34*).—Diagrams are given showing how different sizes of sweet oranges, Satsuma oranges, pomelos, mandarins, lemons, and limes should be packed. The

size measurements of the boxes used are given in each case and brief suggestions given regarding picking, packing, and handling the fruit. Kumquats, it is stated, should be packed in quart baskets and shipped in strawberry carriers.

Smyrna figs, G. E. COLBY (*California Sta. Rpt. 1899-1901*, pt. 2, pp. 242, 243).—Analyses are given of dried packed commercial Smyrna figs grown at Fresno in 1900 and of other dried but unpacked figs of the same crop. An analysis of imported packed Smyrna figs is given for comparison. The California packed Smyrna figs were very large, averaging $\frac{3}{4}$ oz. in weight, and had apparently not gone through the sweating process. The skin appeared thicker than on ordinary Smyrna figs and tougher. This fruit contained 33.43 per cent of water as compared with 21.06 per cent in the imported Smyrna figs. Recalculating the data on the basis of the same water content for both the comparative composition is as follows:

Composition of California and imported Smyrna figs.

	California grown.	Imported.
	<i>Per cent.</i>	<i>Per cent.</i>
Water	21.06	21.06
Ash	1.72	1.80
Proteids	4.37	4.06
Crude fiber	8.02	10.58
Fat91	
Sugar (grape and fruit)	68.92	62.50

This shows $1\frac{1}{2}$ per cent more sugar and nearly $\frac{1}{3}$ per cent more proteid for the California fruit than for the imported figs. Three varieties of unpacked figs ranged in water content from 23.02 per cent to 24.25 per cent; protein, from 3.94 per cent to 4.42 per cent; and sugar, from 62.5 per cent to 64.10 per cent. An analysis of the seed of the dried California-grown Smyrna fig Black Bulletin gave the following data: Water, 6 per cent; protein, 14 per cent; carbohydrates (showing a few starch grains), 13.5 per cent; fat, 34.4 per cent; fiber, 30.4 per cent; and ash, 1.7 per cent.

Culture and preparation of cacao in Trinidad, A. ÉLOT (*Culture et préparation du cacao à la Trinidad*. Paris: Augustin Challamel, 1900, pp. 31, pls. 2, figs. 3).—The climate and soil of Trinidad are discussed, together with the methods observed in that island in cacao culture and preparation for market.

The tea plant, F. COULOMBIER (*L'arbre à thé*. Paris: Augustin Challamel, 1900, pp. X+164, pls. 12, figs. 26).—An elementary work on tea culture, beginning with the soil, climate, and planting of the seed, and including all the cultural operations to the fermentation, drying, packing, and disposal of the product. It is designed as a catechism in tea culture for planters.

Tests of potash fertilizers on vines, E. MARRE (*Prog. Agr. et Vit. (Éd. L'Est)*, 24 (1903), No. 1, pp. 13, 14).—By the use of sulphate of potash the average yield of grapes per hectare in 3 different experiments was increased 8, 11, and 20 per cent, respectively, over the yields obtained when only superphosphate and nitrate of soda were used.

The preparation of Malaga raisins, V. SEBASTIAN (*Queensland Agr. Jour.*, 11 (1902), No. 5, pp. 343-346).—The methods of preparing Malaga grapes, both in Spain and in California, are described in considerable detail.

Expedition to Central and South America, P. PREUSS (*Expedition nach Central- und Südamerika*. Berlin: Kolonial-Wirtschaftliches Komitee, 1901, pp. 452, pls. 20, figs. 78, plan 1).—Under the direction of the Kolonial-Wirtschaftliches Komitee the author made an agricultural expedition into Central and South America. Following a description of several of the countries of South America and Mexico and of the characteristics of the agriculture and people in the different countries, the methods followed in the various districts in the culture, curing, and preparation for market

of cacao, vanilla, Peru balsam, coffee, caoutchouc, gutta-percha, and nutmegs are given. The best practices in the case of each of these different crops are concisely summarized. The most attention has been given to the culture of coffee, cacao, and vanilla. An inventory of the plant material, etc., gathered on the journey is given in an appendix.

First year in tropical agriculture, G. SAUSSINE (*La première année d'agriculture tropicale*. Paris: Augustin Challamel, 1900, pp. VI+316, figs. 84).—An elementary school text-book on the general subject of tropical agriculture. A discussion of tools, stock, and the usual tropical plants is included.

Refrigerator cars (*Canad. Hort.*, 25 (1902), No. 10, p. 407).—It is reported that the Hanrahan refrigerator cars running between Grimsby and Ottawa have carried fruit as satisfactorily as the regular express cars.

Forcing branches of hardy shrubs (*Gardening*, 11 (1903), No. 248, p. 121).—It is stated that branches of flowering shrubs may be brought into bloom during the winter by timely cutting and bringing into the greenhouse. The branches should be put into a barrel of water in a warm house and occasionally sprinkled with lukewarm water. The flowering almond (*Prunus amygdalus*) is especially suited for this work, and if wanted for the Christmas trade it should be cut and brought into the house the latter part of November. Forsythia and ribes may also be treated in the same manner. The forsythia requires a little longer time to come into bloom than the flowering almond, and the ribes about the same length of time. Hardy magnolias have also proved very satisfactory in this work. The white-flowered kinds are stated to produce flowers of a much finer and more satin-like texture than those grown out of doors. Magnolia flowers thus obtained are very durable, remaining in perfect condition sometimes for 8 to 10 days after the development of the flowers.

Correlation between the color of roots of carnations and the flowers (*Rev. Hort.* [Paris], 74 (1902), No. 24, p. 567).—It is stated that Chabaud has observed that carnations with red roots have red flowers, those with white roots produce white flowers or a white ground, and those with yellow roots produce yellow flowers or a yellow ground. The advantage to be gained from this knowledge is in the production of new varieties, the color of the flowers being indicated by the color of the seedling roots without waiting for the plants to blossom.

Raising gladiolus hybrids (*Amer. Gard.*, 23 (1902), No. 418, p. 834).—An account is given of the origin of the hybrid gladiolus *Princeps*, originated by D. W. Van Fleet. This is a very vigorous growing gladiolus of a true *Salvia* scarlet color. It was obtained from seed produced as a result of hybridizing *G. cruentus* from South Africa with a large-flowered garden variety of the Childsii strain. This gladiolus has been successfully grown nearly everywhere in the United States and in several European countries.

The book of orchids, W. H. WHITE (*London and New York: John Lane, 1903, pp. 118, pls. 11*).—This is the eighth in the series of Handbooks of Practical Gardening, edited by H. Roberts. The work discusses orchid houses, materials for potting, watering, diseases, etc., and gives brief accounts of 89 genera of orchids and their species, with many cultural suggestions.

Greenhouse construction and management, S. T. MAYNARD (*Massachusetts State Bd. Agr.*, Bul. 6, 1902, pp. 29-40, figs. 16).—A popular discussion of materials, foundations, superstructures, painting, glazing, heating, ventilating, beds, benches, and insects.

FORESTRY.

Economics of forestry, B. E. FERNOW (*New York: Thos. Y. Crowell & Co., 1902, pp. XII+530*).—The author treats of forestry from the standpoint of political economy, aiming to present such information as is required to fully appreciate the proper rôle of forests and forest products in public affairs. This is one of a very few

such books, and is probably the only one published in the English language which attempts a systematic discussion of the various topics treated. The book is not only a contribution to economic science, but also to the technical literature of forestry. The chapters are: The relation of the State to natural resources, the forest as a resource, the forest as a condition, forest and forestry defined, the business aspects of forest production, natural history of the forest, silviculture, forest economy, principles and methods of forest policy, forest policies of foreign nations, the forest conditions of the United States, and the forestry movement in the United States. A bibliography and numerous notes, tables, and other references are added in the appendix.

Among green trees, JULIA E. ROGERS (*Chicago: A. W. Mumford, 1902, pp. XXII+202, pls. 25, figs. 196*).—This is a popular treatise describing a limited number of trees, and giving account of their physiological activity, their cultivation, and their systematic relations. In all about 125 different kinds of trees are described, the author aiming to include the more common and important trees growing in the States north of Virginia and Arkansas and east of the Rocky Mountains. The first part of the book is taken up with a nature-study consideration of trees, followed by chapters on the growth, reproduction, and other physiological functions of the trees. In the third part of the book the horticultural phases of tree growth are discussed, and directions given for planting, pruning, and protection of different kinds of trees. The book concludes with a description of the species as indicated above.

Studies of trees in winter, ANNIE O. HUNTINGTON (*Boston: Knight & Millet, 1902, pp. XVIII+198, pls. 79, figs. 3*).—A description is given of the winter aspect of a number of the deciduous trees occurring in the northeastern United States, with an introduction by C. S. Sargent, of the Arnold Arboretum. The characters upon which the recognition of the trees in winter depend are based largely upon the aspect of the trunk and branches, stems and twigs, leaf scars, bud scars, and shape and position of the buds. After describing these at length the author takes up and describes about 40 different kinds of trees, the best known of which are the horse chestnut, maples, ashes, walnuts, hickories, birches, beeches, chestnut, oaks, elms, sycamore, locusts, lindens, magnolias, willows, poplars, larch, etc. In addition to describing the winter aspect of these trees so that they may be readily recognized, notes are given on the distribution and general characters of the trees, together with statements regarding their value from economic and other standpoints. The book is an important contribution to our knowledge of the forest flora of a considerable portion of this country, since the species described are not by any means restricted to the northeastern part of the country.

Timber resources of the United States (*Tradesman, 48 (1903), No. 10, p. 74*).—According to recent estimates the merchantable timber of the United States, not including Alaska or the island possessions, aggregates 1,300,000,000,000 ft. B. M. Another estimate, based upon the annual product and the prospective life of the lumber industry from the standpoint of those who are familiar with the various sections, is somewhat lower—in round numbers 1,093,000,000,000 ft. B. M. This estimate takes into account only the timber which is adapted to use as saw timber, and does not take into consideration the production of cord wood, posts, poles, etc.

History of the lumber industry in the State of New York, W. F. FOX (*New York State Forest, Fish, and Game Com. Rpt. 1900, pp. 237-305, pls. 24, map 1*).—This is a reprint of Bulletin 34 of the Bureau of Forestry of this Department (E. S. R., 14, p. 575).

Manuring woodlands (*Farmers' Gaz., 61 (1902), No. 21, p. 388*).—A summary is given of investigations conducted on the continent of Europe in which the value of fertilizers in promoting forest growth was studied. In several examples the increased growth of the forest trees due to the dressings of fertilizers and cultivation much more than paid for the cost of application. In one experiment where

similar plats of Scotch pine were planted, the first was retained as a check plat, the second received 700 lbs. of slag and 4 cwt. of kainit, while the third plat received 12 cwt. each of slag and kainit. The trees at the age of 8 years were from 30 to 40 in. in height on the unmanured soil, 50 to 69 in. in height on the plat receiving the smaller amount of fertilizer, and from 58 to 88 in. in height on the one receiving the larger application.

The use of nitrate of soda in silviculture, J. HUBERTY (*Bul. Soc. Cent. Forest. Belg.*, 9 (1902), No. 7, pp. 411-421, pls. 2).—The results of experiments with nitrate of soda upon the growth of forest trees in nurseries are given. The experiments were conducted in a number of regions with almost uniform results. The application of from 300 to 400 kg. of nitrate of soda per hectare had a marked effect upon the young trees, causing a greatly increased growth of spruces, white pine, oaks, maples, etc. The increase in growth was considered much in excess of the cost of the fertilizer and its application.

Tree growing in Nebraska, C. E. BESSEY (*Forestry and Irrig.*, 8 (1902), No. 11, pp. 453-456, figs. 2).—A brief popular description is given of the recent undertaking of this Department in tree planting in western Nebraska. For this purpose 2 forest reserves have been proclaimed which embrace 212,000 acres. The tree planting which was undertaken in the Sand Hills of Holt County about 1890 by this Department is briefly described, and the trees are now said to be from 16 to 18 ft. high and growing vigorously. The predominating species are pines, and the results obtained seem to indicate the possibility of foresting this area.

Recent forest fires in Oregon and Washington, W. T. COX (*Forestry and Irrig.*, 8 (1902), No. 11, pp. 462-470, pl. 1, maps 2).—An account is given of the severe forest fires which occurred during September in Washington and Oregon. In all more than 600,000 acres were swept by fire. In some regions not a single living tree remains to seed the burned areas. In a few places the Douglas spruce remains in sufficient abundance to secure the reproduction of the forest, but cedar, arbovitæ, and hemlock, being less resistant to fire, were invariably killed. The money loss in both States is estimated at more than \$12,750,000.

A plantation of European larch, A. F. HAWES (*Forestry and Irrig.*, 8 (1902), No. 11, pp. 472-474, fig. 1).—An account is given of a small plantation of European larch near New Haven, Conn., which was planted about 23 years ago, the trees being imported from Europe. When planted the trees averaged 2½ ft. in height and were set in rows 4 ft. apart in each direction. A study was made of the stand of trees and the value estimated. The present value of the plantation is estimated to be about \$80 per acre. A large proportion of trees has been suppressed owing to close planting. Through ignorance of the intolerance of larch to shade this experiment has proved a failure, where had more open planting been adopted the results might have been profitable.

A contribution to the knowledge of the timber of the yew tree, G. THOMS (*Korbl. Naturforsch. Ver. Riga*, 45 (1902), pp. 28-33).—The yew tree (*Taxus baccata*) is said to live to a great age and attain a diameter of a meter or more. Its distribution is briefly indicated, and analyses of the ash of the wood are given. The specific weight, as compared with that of oak, beech, ash, birch, etc., is shown to be greater than all those woods.

The mesquite, S. J. HOLSINGER (*Forestry and Irrig.*, 8 (1902), No. 11, pp. 447-453, figs. 5).—A description of the habits and uses of the mesquite (*Prosopis juliflora*) is given. While as a rule this plant over the greatest extent of its range does not attain tree-like proportions, yet in parts of Colorado and Arizona it is met with growing to a height of 35 to 65 ft., with a diameter of 18 to 30 in. or more. As an economic plant it is one of the most valuable of the southwestern region. Its wood is close, hard grained, and adapted to various uses; while as an ornamental and shade tree it is superior to many other species. On account of the great extent of the root develop-

ment it is considered valuable to protect soils against erosion, and its reproduction and growth as coppice is rapid and the second growth wood which matures in from 10 to 20 years is said to be better than the original growth. In addition to its timber value, the beans which are produced in great abundance have a distinct value both as food and feeding stuff. The bark also contains a high percentage of tannin which is locally used, and a gum which is capable of making fine mucilage exudes from the branches. The distribution of the mesquite is indicated and its related species, the screw bean (*P. pubescens*), is also briefly mentioned.

Difficulties and errors in stem analysis. A. S. WILLIAMS (*Forestry Quart.*, 1 (1902), No. 1, pp. 12-17).—A number of the difficulties which are met with in attempting stem analysis, and the sources of a number of errors are pointed out.

DISEASES OF PLANTS.

Spore resistance of loose smut of wheat to formalin and hot water. W. STUART (*Proc. Indiana Acad. Sci.* 1901, pp. 275-282).—On account of the apparent difference in the resistance of the spores of loose smut to various media, a series of experiments was undertaken in which spores from smutted heads were subjected to various germination tests. Before being placed to germinate, they were treated with varying strengths of formalin and different temperatures of hot water for varying periods of time. As a result of the experiments it was concluded that the smut spores themselves are easily destroyed by either formalin or hot water treatments, but owing to the somewhat impervious nature of the seed coats of wheat the spores frequently find lodgment in the interstices and it is difficult to reach and kill them in the ordinary methods of treatment. To render the seed coats of wheat susceptible to such agencies as are commonly employed for the prevention of smut, it is recommended that the seed should be soaked for several hours in cold water prior to the treatment. When so treated, a short immersion in an 0.18 per cent solution of formalin or 10 minutes in water at 120° did not materially influence the germination of the wheat and destroyed the smut.

Experiments in the prevention of smut in oats. T. JOHNSON (*Jour. Dept. Agr. and Tech. Instr. Ireland*, 2 (1902), No. 3, pp. 426-436, figs. 2).—An account is given of experiments conducted for the prevention of oat smut (*Ustilago avenae*) in which the relative efficiency of potassium sulphid, copper sulphate, formalin, hot water, and the "sar" or sodium sulphid solution, previously described (E. S. R., 10, p. 154), were tested. As a result of the experiments it is shown that smut of oats, which is very prevalent in the west of Ireland, can be almost entirely prevented by treatment of the seed, and when the cost of application and efficiency is considered the "sar" or sodium sulphid solution is preferred.

The specialization of Erysiphe graminis. E. MARCHAL (*L'Ing. Agr. Gembloux*, 13 (1902), No. 1, pp. 10-13).—An account is given of a series of experiments conducted with *Erysiphe graminis* to determine the possibility of cross inoculations of this fungus from one host to another. There are said to be about 55 species of grasses affected by this fungus, and the experiments briefly outlined were conducted from March to June, 1902. Plants of wheat, barley, rye, and oats were cross inoculated with the Erysiphe from different hosts. In about 15 days an abundant development took place but only in those cultures where the spores had been taken from host plants of the same species. A series of experiments was then undertaken in which the attempt was made to transfer the mildew from various wild grasses to the cultivated cereals. As a result of all his experiments, the author is led to conclude that there are a number of well defined forms of *Erysiphe graminis* which are specialized to their respective hosts. Morphologically no differences can be detected, but infection experiments invariably failed when the species of host plants were not rather closely related.

On the specialization of *Erysiphe graminis*, E. MARCHAL (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 3, pp. 210-212).—A report is given of studies made of this common grass mildew in which reciprocal inoculations were made with material obtained from a number of different host plants. The results of his experiments, which have been already noted above, show that *Erysiphe graminis* has become specialized on a number of hosts. Descriptions are briefly given of the specialized forms, to which the author gives names based upon the principal host plants. The form species recognized are *tritici*, *hordei*, *secalis*, *avenae*, *poae*, *agropyri*, and *bromi*.

Cotton disease in Egypt, G. DELACROIX (*Agr. Prat. Pays Chauds*, 2 (1902), No. 8, pp. 135-143; *Jour. Agr. Trop.*, 2 (1902), No. 14, pp. 231-233).—A description is given of a cotton disease in Egypt, the diseased material of which was sent to the author for determination. From the description of the disease furnished the author, and the examination of the infected material, he is led to believe that the disease is identical with that known in the United States as cotton wilt. A study of the parasite offers no differences so far as he can determine from that described as *Neocosmospora vasinfecta* (E. S. R., 11, p. 944). The author states that the resistance of Egyptian cotton to disease observed in this country does not seem to have been noted in Egypt.

Cucumber and melon leaf blotch (*Jour. Bd. Agr. [London]*, 9 (1902), No. 2, pp. 196-198, pl. 1).—The fungus causing this disease was first observed and described as *Cercospora melonis* in 1896, and has spread with marked rapidity. It attacks the foliage, causing small pale green spots on the upper surface of the leaf. These gradually increase in size, passing from gray to a brownish or yellowish color. Frequently the leaf becomes dry and crumbles within 24 hours of the first appearance of infection. Such dead leaves are a source of continued infection and should be destroyed. The disease seems to assume destructive tendencies only upon plants grown under glass where high temperature and excessive moisture are present. Such conditions result in the production of soft growth rendering the attack of the fungus possible. The distribution of the disease through shipping boxes has been demonstrated. For preventive measures the spraying with potassium sulphid is recommended. The diseased leaves should be removed and burned, and after the diseased crop is removed the soil should be thoroughly disinfected.

The finger-and-toe in turnips (*Jour. Bd. Agr. [London]*, 9 (1902), No. 2, pp. 145-149, fig. 1).—A description is given of the club root of turnips caused by *Plasmodiophora brassicae*. This disease in addition to attacking turnips affects nearly all plants belonging to the family Cruciferae. As means for the prevention of the disease the application of fresh burned lime to infected land is recommended. In order to secure the best results this should be spread on the land 18 months or more before the turnip crop is sown. Other forms of lime are more or less effective but none are as efficient as the common burned limestone, which is slaked just before spreading. In addition to the treatment with the lime the rotation of crops is recommended, and turnips or similar crops should not occupy the land oftener than once in 8 years. Experiments have shown that acid fertilizers encourage the development of this disease and should in no case be used. The author states that while no varieties seem entirely immune to disease some appear markedly resistant.

Notes on apple rusts, H. H. WHETZEL (*Proc. Indiana Acad. Sci.* 1901, pp. 255-261).—Notes are given on the general prevalence of apple rust throughout the region, and attention called to the fact that while the fungus was exceedingly abundant on cedars during 1900 it was markedly scarce the following season. The Roestelia stage was sufficiently abundant for the purposes of investigation during the summer of 1901, although not as abundant as the previous year. An experiment was attempted in which parts of apple trees were inclosed with cheese cloth just as the buds were beginning to swell and when the teleutospores had not yet ripened on the cedars. The protected leaves were examined from time to time, and while infected

to some extent they did not exhibit nearly as many spots as the unprotected portions of the tree. It is believed that the infection was caused through the development of the sporidia of the fungus and not directly through the distribution of the teleutospores. Laboratory experiments were conducted with the teleutospores, in which it was found that the best germination took place on slides which were moistened and placed in the sunlight under bell jars. This allowed the spores to dry slowly, thus affording natural conditions for sporidia production. The galls produced on the cedar are believed to be perennial. The mycelium passing the summer in the old gall produces new outgrowths and a second crop of spores in the following spring. In this way the occurrence of the Roestelia stage of the disease in 1901, following an almost total disappearance of the cedar apples, may be explained. Marked differences are reported on the immunity of different varieties of apples as observed in the different orchards.

Pink rot, an attendant of apple scab, J. CRAIG and J. M. VAN HOOK (*New York Cornell Sta. Bul. 207, pp. 161-171, pls. 2, figs. 5*).—Attention is called to a very destructive rot which accompanies and follows apple scab. This is caused by a parasite which appears only on apples infested with scab. It is first noticed as a thin gray mildew, always thicker around the margin of the scab spots. Later it assumes a pink color, due to the maturing of the fungus. The apple scab fungus as it matures ruptures the skin of the apple and the edges are left somewhat upturned, and it is through these broken surfaces that the pink fungus gains entrance. The first appearance on the apples is the browning of the epidermis about the scab spots. This gradually extends in all directions, until by the merging of the spots large areas or the entire surface may be involved. As the spots increase in size the surface becomes sunken by the dissolution of the solid parts of the apple underneath, as well as the evaporation of water through the spots. The fungus, which has been identified as *Cephalothecium roseum*, is not ordinarily considered as a parasite, but usually grows upon decaying vegetable matter. The atmospheric conditions for spraying were very unfavorable during this season, and as a consequence there was an unusual development of apple scab. The injury caused by the scab made possible the abundant development of the pink fungus. Good tillage, careful pruning and spraying, which will result in the production of apples free from scab, would also prevent the occurrence of this pink rot. Experiments were carried on to test the practicability of disinfecting apples by dipping or fumigating them to prevent the growth of this fungus. Samples were dipped in solutions of copper sulphate and formalin and were fumigated with formaldehyde gas and with vapors of sulphur, the best results being obtained where the formaldehyde gas was used. Storing the apples at low temperature will retard the development of the pink rot, but it is probable that removing fruit from cold storage would increase the rapidity of the decay.

The bitter rot of apples, H. VON SCHRENK and P. SPAULDING (*Science, n. ser., 16 (1902), No. 408, pp. 669, 670*).—A description is given of recent investigations on the origin and distribution of the bitter rot of apples, a note on which has been given elsewhere (*E. S. R., 14, p. 367*). It is claimed that the bitter rot can be traced to canker spots on the limbs of the apple tree. Spores from apples inoculated into living apple branches produced the canker, and healthy apples reinoculated from the canker produced the bitter-rot disease on the fruit. Inoculations of pure cultures gave similar results, and it appears that there is a causal relation between apple cankers found in the orchard and the bitter-rot disease. It is considered probable that the fungus *Glaeosporium fructigenum* is capable of living both in the bark and fruit of the apple. This fact is important in assisting apple growers to combat the disease.

Brown rot of stone fruits, F. T. BIOLETTI (*California Sta. Rpt. 1899-1901, pt. 2, pp. 330-333, fig. 1*).—The brown rot of stone fruits caused by *Monilia fructigena* has

been observed in California for some time, but until 1900 did not occasion very serious damage. During that summer 50 per cent of the prune crop in one locality was destroyed and in another it was estimated that 25 per cent of the apricots were seriously affected. As there appeared to be a tendency on the part of the disease to spread throughout the State, a brief report is given describing the disease and giving suggestions for its preventive treatment. It is recommended that all mummy fruits be collected and destroyed and trees given thorough spraying with Bordeaux mixture, one application to be given before the blossoms open and a second after the fruit has set. It is believed that the use of a winter wash consisting of lime, salt, and sulphur would doubtless be effective against the brown rot. In the case of late ripening varieties a third spraying should be given after the others as recommended above, but in this case a copper acetate solution is to be preferred, as the Bordeaux mixture would stain the fruit at this time.

A new disease of bananas (*Queenstown Agr. Jour.*, 11 (1902), No. 4, p. 284).—A brief note is given of the nematode disease of bananas in Egypt, which has been noted (E. S. R., 14, p. 581). This disease is said to have been noted some time since in Australia and to have been investigated by the pathologist of the department of agriculture of that country.

Brunissure of the grape, J. DUFOUR (*Prog. Agr. et Vit. (Éd. L'Est)*, 23 (1902), No. 36, pp. 279, 280).—According to the author the disease known in France as brunissure has been attributed to a number of different causes, among them fungi, various insects, physiological causes, etc. In the present contribution he gives a description of a form of the disease which has been quite prevalent during the past season, which is characterized by the presence of minute larvæ on the surface of the diseased leaves. When examined microscopically these larvæ seem to resemble to a considerable degree those of *Phytoptus vitis*. There are said also to be certain acarids of the genus *Phyllocoptes* which cause a form of brunissure on cherries, plums, nut trees, etc. It is believed that these insects are widely distributed and that they are the evident causes of certain forms of the disease which is generally described under the name brunissure.

A cause of brunissure, L. RAVAZ (*Prog. Agr. et Vit. (Éd. L'Est)*, 23 (1902), No. 43, pp. 481-486).—According to the author's investigations brunissure seems to attack certain varieties of the grape more than others, and apparently those grafted upon certain stock are the most susceptible to the disease. There appears to be a relation also between the disease and the productivity of the varieties, those yielding most abundantly being most subject to the disease. The tendency to disease may be diminished by close pruning so as to reduce the production of fruit, and by stimulating the vegetative growth through the use of fertilizers, irrigation, and cultivation, or by the selection of vigorous resistant stocks.

On the possibility of combating the downy and powdery mildew of grapes by a combined fungicide, J. M. GUILLON (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 4, pp. 261, 262).—A study has been made of mixtures of sulphur and the principal copper fungicides in order to ascertain whether a combination of the two might not be practically useful in controlling both these diseases. In general the sulphur, either sublimed or triturated, remained on the surface of the liquid, but the author found that thoroughly mixing the sulphur with the lime of the Bordeaux mixture or the carbonate of soda in Burgundy mixture would cause its complete suspension in the liquid for a considerable time. The suspension of the sulphur can be further brought about by the use of a small amount of resin. When used with verdigris the sulphur should be thoroughly mixed and the liquid of the fungicide kept agitated. In no case was the adhesive property of the fungicide lessened by the presence of the sulphur, and the mixture of sulphur and copper seemed to be advantageous for the control of both diseases.

Experiments for the prevention of gray rot, L. RAVAZ (*Prog. Agr. et Vit. (Éd. L'Est)*, 23 (1902), No. 35, pp. 250-253).—During the past season the attack of

Botrytis cinerea on certain varieties of grapes has been of exceptional severity. Usually this mold is saprophytic, but under the conditions which have recently existed it has become a parasite of great activity, destroying the fruit in all stages of development. The application of liquid fungicides to the grapes is said to be attended with certain difficulties, and the author has investigated the subject of powders which do not offer the same objection. He recommends the use of either a mixture of 90 per cent gypsum and 10 per cent copper sulphate or 80 per cent gypsum and 20 per cent neutral verdigris. If it is found desirable powdered sugar may be added, in which case the copper will be present in the form of a sucrate.

On the resistance of *Botrytis cinerea* to metallic poisons, L. DEGRULLY (*Prog. Agr. et Vit. (Éd. L'Est)*, 23 (1902), No. 38, pp. 330-332).—An editorial review is given of investigations on the resistance of a number of molds to metallic poisons. The experiments reported were conducted with *Mucor mucedo*, *Aspergillus niger*, *Botrytis cinerea*, and *Penicillium glaucum*. The spores of these fungi were cultivated on the media containing different quantities of salt, and the *Penicillium* was found to be the most resistant. The toxicity or poisonous property of the metals in the increasing order of progression was manganese, zinc, copper, iron, lead, nickel, cadmium, cobalt, mercury, and thallium, the sulphates of the metals being the forms used. In another series of experiments it is stated that spores of *Penicillium* which germinate in the presence of metallic poisons give a growth, the spores of which are more resistant than those of the first generation. In this way it seems that molds in general are able to increase their resistance to toxic substances. The importance of this on the treatment for the prevention of the disease of grapes due to *Botrytis cinerea* is very great.

A form of *Gloeosporium nervisequum* on plane trees, J. BEAUVÉRIE (*Ann. Soc. Bot. Lyon*, 26 (1902), p. 5; abs. in *Bot. Centbl.*, 90 (1902), No. 28, p. 29).—The ordinary form of *Gloeosporium nervisequum*, which is said to be identical with *G. platani* and *G. valsoideum*, is found only upon the leaves of the host plant. A new form is described which attacks the branches and twigs, the mycelium entering the cortical layer and extending to the medullary rays and pith. The pycnidia are formed in the cortex. When the attack is severe the trees are frequently entirely destroyed.

Concerning *Tuberculina persicina*, E. MARCHAL (*Bul. Soc. Cent. Forest. Belg.*, 9 (1902), No. 5, pp. 332, 333).—The acidia produced upon *Pinus sylvestris* by *Cronartium asclepiadeum* are said to be frequently attacked by the fungus *Tuberculina persicina* to the complete obliteration of the characteristics of the former fungus. It has been previously claimed that *Tuberculina* is parasitic upon the *Cronartium*, but the author doubts the accuracy of this statement and thinks that it is merely an association, the *Tuberculina* being able to live only in tissues which have been disorganized by the rust fungus. A related species (*T. maxima*) is said to be associated with the acidia produced on the white pine by *Cronartium ribicolum*.

The rust of spruces, E. MARCHAL (*Bul. Soc. Cent. Forest. Belg.*, 9 (1902), No. 5, pp. 333, 334).—A brief description is given of the rust of spruces produced by *Chrysomyxa abietis*. This disease is said to prefer moist localities and is most abundant in valleys. The meteorological conditions which occur in the spring at the time of the germination of the teleutospores are said to exercise a marked influence on the disease, it being favored by considerable humidity. The disease was present in 1899 and in 1900, but in 1901 it had almost entirely disappeared.

Two fungus diseases of the white cedar, J. W. HARSHBERGER (*Proc. Acad. Nat. Sci. Philadelphia* 1902, pp. 461-504).—The white cedar (*Cupressus thyoides*), which ranges from Maine to Florida and west to the Mississippi, is said to be the host plant for 19 species of fungi, most of which are not of serious importance. The only species considered as serious parasites are *Gymnosporangium bisepatum* and *G. ellisii*. These 2 fungi are very prevalent on the white cedar in New Jersey. The swellings

produced by *G. bisepatum* are usually nodose, increasing year by year until they attain a size of 6 to 8 in. in diameter. Those produced by the second species are never as thick, but the involved branches radiate in a fan-like growth resembling witches' brooms. The effect of the different fungi upon the tissues of the host is shown, and the belief is expressed that the fungi cause marked metabolic changes in the stem, accompanied by the considerable accumulation of resin and other substances.

Studies of some tree-destroying fungi, G. F. ATKINSON (*Trans. Massachusetts Hort. Soc. 1902, I, pp. 109-130*).—A report is given of a lecture, in which the author described *Polyporus borealis*, *P. sulphureus*, *P. igniarius*, *Trametes abietis*, and *Rhizoctonia* sp. The effect of these different fungi upon the trees is shown and the methods of growth and distribution of the fungi are indicated.

Suggestions for the removal of epiphytes from cacao and lime trees, A. HOWARD (*West Indian Bul., 3 (1902), No. 2, pp. 189-197*).—A discussion is given of the presence of epiphytes upon cacao, lime, and other trees, and suggestions given for their removal. The larger forms, like ferns, orchids, etc., are best removed by hand, while the smaller ones can probably be best removed by spraying the trees with a 6 per cent solution of copper sulphate or one of the resin compounds.

The general treatment of fungoid pests, A. HOWARD (*Imp. Dept. Agr. West Indies, Pamphlet No. 17, 1902, pp. 43, figs. 5*).—A general discussion is given of the various diseases caused by fungi, and suggestions given for their prevention.

ENTOMOLOGY.

Some miscellaneous results of the work of the Division of Entomology (*U. S. Dept. Agr., Division of Entomology Bul. 38, n. ser., pp. 110, pls. 2, figs. 9*).—*The southern grain louse*, T. Pergande (pp. 7-19).—Notes are given on the appearance and habits of this insect as learned through correspondence and newspaper clippings. The life history of the species is not well understood. A description is given of the wingless and migratory females. A number of natural enemies are known, including ladybirds and an internal parasite, *Lisiphlebus tritici*. No artificial remedies are effective.

Report of an investigation of diseased cocoanut palms in Cuba, A. Busck (pp. 20-23).—An investigation of the diseased cocoanut palms in Cuba was carried out with the result that a fungus (*Pestalozzia palmarum*) was found to be the primary cause of the disease. The trunk is destroyed within 3 months after the beginning of the attack and is then completely disintegrated by white ants and other insects. For preventing the spread of the disease the author recommends cutting down and burning diseased palms. The insects found upon the cocoanut palm were few in number and of little or no economic importance.

The palm and palmetto weevils, F. H. Chittenden (pp. 23-28).—Descriptive economic and biological notes are given on *Rhynchophorus palmarum* and *R. cruentatus*. A number of insects were found associated with the first named species, among which were 2 species of mites which are doubtless of some value in destroying the weevils. *R. cruentatus* has been observed at Ft. Ogden, Fla., on seedling dates, the trunks of which it thoroughly destroyed. The treatment recommended for this insect is both cultural and mechanical. It is suggested that young trees or wild species of palm be cut down or wounded; the sap which exudes from wounded trees strongly attracts the beetles and they may thus be easily captured.

Notes on the rhinoceros beetle, F. H. Chittenden (pp. 28-32).—Notes are given on the habits and life history of *Dynastes tityus*. The larva of the insect is described for the first time and descriptions are given of the other stages.

Notes on enemies of mushrooms and on experiments with remedies, A. Busck (pp. 32-35).—The chief enemies of mushrooms are considered as being snails, roaches,

dipterous maggots, and mites. Snails may be captured under loose boards; roaches may be driven away by pyrethrum and bisulphid of carbon; the attacks of maggots may be partly prevented by screening windows and by liberal use of pyrethrum. The greatest damage to mushrooms is due to *Tyroglyphus lintneri*. A number of remedies were tried without encouraging results. These remedies include bisulphid of carbon, pulverized sulphur, vapors of sulphur, pyrethrum powder, hydrocyanic-acid gas, tobacco dust, chlorid of lime, gasoline, and moisture. Further experiments will be tried for the purpose of determining an effective remedy.

Notes on Colorado insects, A. N. Caudell (pp. 35-38).—Brief notes on *Nysius minutus*, beet army worm, bean ladybird, apple flea-beetle, cabbage looper, cottonwood leaf-beetle, *Clisiocampa fragilis*, *C. tigris*, bollworm, and grasshoppers.

Grasshopper notes for 1901, L. Bruner (pp. 39-49).—Detailed notes are given on the itinerary of the author through Nebraska, Colorado, and Wyoming to determine the extent of grasshopper ravages. A large number of species of grasshoppers were observed, among which *Melanoplus differentialis*, *M. bivitatus*, *M. atlantis*, *M. packardii*, and *M. femur-rubrum* were most important. Other species were found on prairies and uncultivated grounds feeding upon wild plants. In some localities the grasshoppers appear to breed chiefly in alfalfa fields and along roadsides. The author believes that the destruction of birds is in some localities responsible for the great increase in the number of grasshoppers. The other causes for this abnormal increase are the abandonment of cultivated fields, allowing weeds to grow too extensively, failure to burn prairies, and growing alfalfa without disking the ground in the spring.

Killing destructive locusts with fungus diseases, L. Bruner (pp. 50-61).—A detailed account is given of the various fungus diseases which have been used in destroying locusts. The author experimented with the most of these parasitic fungi and concludes from his experiments that the best results are obtained from the use of native fungi, and that the value of introduced fungi in destroying locusts has been greatly overestimated. It is believed that the cultures distributed from Australia under the name *Mucor racemosus* are properly labeled, but that they do not contain the fungus which caused the death of the grasshoppers from which the cultures were made.

The conflict of the Russian Zyemstvos with the enemies of agriculture, V. Moracherski (pp. 61-66).—An abstract of a paper previously noted (E. S. R., 11, p. 658).

The tobacco-stalk weevil, F. H. Chittenden (pp. 66-70).—Notes are given on the habits and life history of this insect, based partly on the correspondence from L. H. Shelfer in Texas. The species is *Trichobaris mucorea* and is closely related to *T. insolita*, which occurs in Florida. In controlling this insect Paris green is found effective. It was also suggested that the tobacco stems should be destroyed as soon as the leaves are cut.

The leaf-mining locust beetle, with notes on related species, F. H. Chittenden (pp. 70-89).—*Odontota dorsalis* is said to have been unusually destructive in the District of Columbia, Maryland, and Virginia during the past season. The injury was most severe to young trees. The beetle is described in its different stages and notes are given on the geographical distribution, food plants, life history, habits, and natural enemies of the species. The beetles may be destroyed by application of an arsenical spray. Notes are also given on *O. rubra*, *O. nerrosa*, *O. bicolor*, *O. horni*, *O. notata*, *O. californica*, *O. scapularis*, *Microrhopala vittata*, *M. xerene*, *M. melsheimeri*, *M. floridana*, *Ocotoma plicatula*, *O. marginicollis*, and *Stenopodius flavidus*.

The bulletin also contains general notes on the introduction of *Liparis monacha* in America, the loss caused by the variegated cutworm in 1900, Mediterranean flour moth in Minnesota and other States, angoumois grain moth in 1901, recent injury by the cigarette beetle, the occurrence of *Dermestes cadaverinus* in the United States, blister beetles injurious to fruit trees, vine chafers, Colorado potato beetle in the South, rice weevil, cane borer, and various other notes from correspondents.

Elementary studies in insect life, S. J. HUNTER (*Topeka, Kans.: Crane & Co., 1902, pp. XVIII + 344, pls. 2, figs. 259*).—This volume contains an account of insect metamorphosis, special senses, protective devices, solitary life, social life, instinct, mutual relations of plants and insects, injurious and beneficial insects, the extent of insect life, geographical distribution of insects, structure, collection and classification of insects, laboratory exercises, habits of ants, form and function of different parts of insects, and an appendix on methods of dealing with injurious insects. In this appendix economic plants are arranged in alphabetical order with brief notes on their chief insect pests. The volume contains many original illustrations and is written for the purpose of inducing students to make personal observations in the field and laboratory on some of the more important biological problems presented by insects.

Report of the State entomologist, W. M. SCHÖYEN (*Larsbr. Offent. Foranstält. Landbr. Fremme, 1901, I, Statsforanstält., pp. 90-129, figs. 27*).—As in previous reports by the author, notes are given on the more important insect pests and plant diseases observed in Norway during the year. The chief pests discussed in the report include *Hydrellia griseola*, injurious to cereals; oat smut; wheat rust; *Charaas graminis*, *Admonia tenaceti*, and *Tipula oleracea*, injurious to grasses; *Plutella cruciferarum*, *Mamestra brassicae*, and *Limax agrestis*, injurious to cabbages and related plants; codling moth, *Argyresthia conjugella*, *Aporia crataegi*, *Hyponomeuta variabilis*, pear psylla, apple plant louse, and oyster-shell bark-louse, injurious to fruit trees; *Nematus ribesii*, *Zophodia conrotutella*, and *Puccinia ribis*, injurious to gooseberries and currants. Brief notes are also presented on the insect and fungus pests of shade trees, conifers, ornamental plants, and also upon a number of household insects.

Studies on insects, E. FLEUTIAUX (*Agr. Prat. Pays Chauds, 1 (1902), No. 6, pp. 768-773; 2 (1902), No. 7, pp. 111-124, figs. 7*).—Notes are given on a number of beetles which have been introduced into Tunis which are likely to be transported by means of shipping.

Experiments were tried with a race of silkworms known as Massourah, from Asia Minor. This race proved to be a very profitable one in Tunis, and it is recommended that more extensive experiments be tried with it.

In combating *Physopus rubrocincta*, an enemy of the cacao, it was found that best results were obtained from the use of kerosene emulsion. Notes are given on the use of sulphur fumes generated by special machines devised for that purpose in the destruction of rice weevils and other insects in various situations. A list is given of insects collected by Landes and Tonin at St. Pierre. Notes are given on *Sphenophorus litatus* injurious to bananas, and a number of insects especially injurious to agriculture in Madagascar.

Injurious insects, E. FLEUTIAUX (*Agr. Prat. Pays Chauds, 2 (1902), No. 9, pp. 377-380*).—Brief notes are given on a number of insects injurious to tobacco and bamboo, and mention is made of certain other butterflies and injurious Diptera. In Madagascar tobacco was injured by *Dermestes bicolor*, *Ptinus fur*, various species of cockroaches, and other insects.

Corn billbugs in Illinois, S. A. FORBES (*Illinois Sta. Bul. 79, pp. 435-461*).—Injury to corn from billbugs has been found to prevail in Illinois chiefly under one or the other of 3 conditions, viz: (1) Where swamp lands are broken up in the spring and planted to corn; (2) where such land is poorly cultivated, allowing coarse grass to grow up again; and (3) where timothy sod is plowed under in the spring and immediately planted to corn. The largest species of billbugs breed chiefly in the bulbous roots of certain coarse sedges or rushes, while the majority of the medium-sized species breed largely in timothy fields. This explains the danger of planting corn immediately after breaking up such land. As a general preventive measure against injury from billbugs it is recommended that grass lands infested by these insects be plowed in the early fall or summer before the time for the hibernation of

the adult insects. This has been found by experience to be a quite effective remedy for preventing infestation by billbugs. Detailed descriptive economic and biological notes are given on a number of species of these insects, including *Sphenophorus parvulus*, *S. placidus*, *S. ochreus*, *S. pertinax*, *S. curvatus*, *S. scoparius*, *S. sculptilis*, and *S. robustus*. *S. parvulus* is said to hibernate in the adult stage. The beetles deposit their eggs in the early summer, the larvæ hatch in June and pupation takes place in July. The adults appear late in July or during August. The most injurious species of those mentioned is *S. ochreus*. A brief bibliography of recent literature on these insects is appended to the bulletin.

Extermination of the cane grub, A. J. BOYD (*Queensland Agr. Jour.*, 10 (1902), No. 6, pp. 468, 469).—The ravages of the cane grub are reported to have been unusually severe. This condition is believed to be attributable in part to the great destruction of moles which took place in consequence of the severe drought. The feeding habits of the mole are briefly considered and notes given on its natural enemies. It is believed that the mole is one of the most valuable helps to the cane grower in preventing damages from the cane grub.

Cleonus punctiventris and green muscardine, S. G. TOPORKOV (*Zhur. Opuin. Agron. [Jour. Expt. Landw.]*, 3 (1902), No. 1, pp. 1-28).—The author found that this beetle does not feed upon grass when it first appears in the spring, and in this respect the author's observations do not agree with those of Danyasz. During the winters of 1900 and 1901 it was found that the beetles did not penetrate into the soil below a depth of 45 cm. and that 87 per cent of the beetles were found in the layer of soil between 9 and 36 cm. below the surface. According to the author's observations there is but 1 generation. The larvæ and beetles are more quickly and seriously affected with the muscardine when they occur in crowded conditions. It is therefore recommended that sugar beets be planted at greater distances from one another in order to prevent the accumulation of the insects in large masses at intervals so great that the fungus does not succeed in passing from one mass of insects to another. The author believes that the muscardine, which is found in the government of Kiev, is not the white variety but rather the green. In combating the attacks of *Cleonus punctiventris* upon sugar beets it is recommended that a rotation of crops extending over 2 or 3 years be adopted in the place of one occupying from 4 to 6 years. This would prevent the destruction of the muscardine in the soil between any 2 successive crops of sugar beets.

Cleonus punctiventris and green muscardine, S. G. TOPORKOV (*Zhur. Opuin. Agron. [Jour. Expt. Landw.]*, 2 (1901), No. 2, pp. 134-168).—In combating the attacks of this insect upon sugar beets, the author believes that no reliance can be placed upon the white muscardine, but that the green and red varieties are quite effective. It is thought that the green muscardine is better adapted than the other varieties to the climatic and other conditions of the government of Kiev. The author summarizes the results of his extensive observations on this insect since 1892. It was observed that the beetles are most affected by the fungus when they occur in large masses in the soil. Numerous observations were made for the purpose of determining the depth to which larvæ penetrate. An examination of the soil to ascertain the number of dead and living larvæ and beetles indicates that the distribution of the muscardine and the intensity of its effect upon the beetles are in inverse proportions to the distances between the individual insects. The author recommends the preservation over winter in cellars of masses of soil containing large quantities of the muscardine. This material may then be scattered upon ground to be infested and may be plowed under. It is also recommended that in the fall the soil be plowed at a depth sufficient to expose the larvæ to the action of frost.

Cleonus punctiventris and muscardine, J. DANYSZ (*Zhur. Opuin. Agron. [Jour. Expt. Landw.]*, 2 (1901), No. 4, pp. 464-482).—This insect is said to have been injurious to sugar beets for the past 30 years. From the results of experiments with

artificial insecticide methods it is believed that the insect can not be thus exterminated or even held sufficiently in check. Great hopes, however, are expressed for the ultimate beneficial effects of the use of white muscardine as a fungus disease for destroying the beetles.

Methods and results of field insecticide work against the San José scale, 1899-1902, S. A. FORBES (*Illinois Sta. Bul. 80, pp. 463-502, pls. 9*).—In this bulletin a report is made on extensive operations conducted in a practical manner and under ordinary conditions in exterminating San José scale in infested orchards. During the progress of this work 4 treatments were used in winter, viz, hydrocyanic-acid gas, whale-oil soap, kerosene emulsion, and lime-sulphur-salt wash. It was found that all of these methods were effective under favorable conditions. Fumigation with hydrocyanic-acid gas is believed to be practically restricted to comparatively small trees and quiet weather, while the California wash has a decided advantage in the persistence of its effectiveness. The 4 insecticides differ in convenience of application, and safety. Considerable injury was done to the peach, and in 1 case to an apple tree, by a kerosene emulsion of only 20 per cent. The total cost of preparation and application did not differ greatly for the 4 insecticides. The fumigation process is much more expensive with respect to cost of materials. From the standpoint of convenience of application the author prefers kerosene emulsion and California wash. As a result of the whole comparison of these 4 insecticides it is concluded that the best treatment for ordinary use against the San José scale consists in spraying in winter with the California wash.

The use of hydrocyanic-acid gas in greenhouses, G. C. BUTZ (*Pennsylvania Sta. Rpt. 1901, pp. 319-395*).—Experiments were made in fumigating greenhouses containing a considerable variety of plants. It is apparently possible to fumigate greenhouses successfully without injury to the plants, provided only 1 or 2 species of plants of about equal hardness are kept in each house. In conservatories and greenhouses with a large assortment of plants the gas can not be used without injury to the more tender species. In the experiments reported in this paper fumigation was begun at about sundown, while the plants were dry, and the length of exposure in every case was 25 minutes. The insects which it was sought to destroy by these experiments were thrips, mealy bug, plant lice, scale insects, and red spider. In 2 greenhouses 0.15 gm. potassium cyanid per cubic foot of air space was employed, while in the third only 0.12 gm. was used. As a result of these experiments a considerable difference in the resisting power of different plants to hydrocyanic-acid gas was found. The various plants in the greenhouses are arranged in 3 categories according as they were uninjured, slightly injured, or totally killed. Ferns, grasses, mosses, begonias, etc., were uninjured; fuchias, geraniums, heliotropes, nasturtiums, palms, cacti, etc., had the tender leaves injured; while *Pellea* and *Tradescantia bicolor* were killed. Plant lice were all destroyed by the fumigation. Isolated mealy bugs were killed, but where they occurred in large masses the older individuals and the eggs were not destroyed. Scale insects were killed, except eggs under old scales. Red spiders were killed only to the extent of about 10 per cent.

The white fly or plant-house aleurodes, W. E. BRITTON (*Connecticut State Sta. Bul. 140, pp. 17, pls. 4, figs. 5*).—The white fly has been the most serious pest of tomatoes in forcing houses for the past 8 years. It also lives on outdoor plants in the garden throughout the summer. Notes are given on its relationship to other insects and on the nature of its injuries and its habits and life history. A detailed description is given of the insect in its various stages, chiefly based on the notes of Westwood. The insect is most injurious in forcing houses to tomato, cucumber, and melon plants, while florists complain of its injury to lantana, heliotrope, and ageratum. A list is given of the food plants upon which the author observed the insect in its nymph stage. A number of remedies have been tried in combating this insect. Fumigation

with tobacco does not kill a large proportion of the insects. Fumigation with hydrocyanic-acid gas kills all of the white flies, but since the tomato is especially susceptible to the effects of this gas, more or less serious injury may be experienced from its use. Whale-oil soap in the proportion of 1 lb. to 5 gal. of water destroys the nymphs, but produces a disagreeable odor. Fir-tree oil at the rate of $\frac{1}{2}$ lb. to 2 gal. of water gives excellent results, but is too expensive. A 15 per cent mechanical mixture of kerosene gives good results in killing the insects, but lends an unpleasant odor to the tomatoes. The best results were obtained from spraying tomato plants with common soap and water in the proportion of 1 lb. of soap to 8 gal. of water.

"Termes taprobanes"—white ants as a pest of trees (*Dept. Land Records and Agr., Central Provinces Bul. 6, 1902, pp. 3*).—Notes are presented on a number of experiments conducted for the purpose of determining effective and convenient remedies for destroying white ants. These experiments were duplicated in a number of different localities under different conditions. Tobacco decoction, kerosene, salt and soap, were among the remedies tried, but all of these gave unsatisfactory results. Excellent results were obtained from the use of Gondal fluid, containing 1 part gum of *Gardenia gummifera*, 2 parts asafetida, 1 part Bazar aloes, and 2 parts castor-oil cake. This fluid is to be applied in a continuous band around the trunks of trees which are to be protected against the attacks of the white ants.

On mites attacking beetles and moths, W. W. SMITH (*Trans. and Proc. New Zealand Inst., 35 (1901), pp. 199-201*).—Brief notes are given on *Uropoda vegetans*, which was observed as a parasite on 9 species of beetles and 2 species of moths. The beetles and moths which are parasitized by this mite have the habit of resting in moist places, and it is believed that the mite thus gains opportunity for attaching itself to its hosts.

The destruction of certain injurious insects, especially Hyponomeuta padella, J. LABORDE (*Compt. Rend. Acad. Sci. Paris, 134 (1902), No. 20, pp. 1149-1151*).—Since hand picking of the caterpillars of *Hyponomeuta* and spraying with ordinary insecticides have been found slow or ineffective methods for destroying this insect, the author conducted a number of experiments for the purpose of developing a more efficient insecticide. The material used in these experiments contained 1,500 gm. pine resin, 200 gm. caustic soda, and 1 liter ammonia to 100 liters of water. It was found that this insecticide readily penetrated the silk threads which protected the larvæ and proved to be an efficient agent for destroying the latter. It appears to be valuable as an insecticide application up to the time of pupation of the insects.

The migratory locusts and means of combating them in our African colonies, L. SANDER (*Die Wanderheuschrecken und ihre Bekämpfung in unseren afrikanischen Kolonien. Berlin: Dietrich Reimer, 1902, pp. 544, figs. 40, maps 6*).—In this volume the author presents an elaborate account of extensive investigations made for the purpose of determining the distribution, habits, and means of combating the migratory locusts of the German colonies in Africa. A detailed historical account is presented on the various outbreaks which have occurred in East Africa, Southwest Africa, Cape Colony, Togo, and Kamerun. An account is given of the anatomy and development of locusts, together with descriptions of the different forms under which they appear. The migratory species which are most important in Southern Africa are *Pachytylus cinerascens*, *P. migratoroides*, *P. sulciollis*, *Schistocerca peregrina*, and *S. paranensis*. An elaborate discussion is given of the following subjects: Migrations of locusts, causes and consequences of their migration, food plants, natural conditions for the rapid multiplication of locusts, peculiarities of the habits of locusts in South Africa, natural enemies of locusts, the remedies which have been adopted for combating the locust, and various official regulations which have been adopted for destroying them. In the chapter on natural enemies of locusts mention is made of various birds, reptiles, insects, and other animals which prey upon or parasitize them, and an account is also given of the fungous and bacterial diseases

which have been tested in destroying them. In a chapter on methods for combating locusts an elaborate account is presented of the various mechanical and chemical remedies with which experiments have been made.

The secondary adaptation of the front leg of *Gryllotalpa vulgaris*, C. VANEY and A. CONTE (*Ann. Soc. Lim. Lyon, n. ser.*, 47 (1900), pp. 151-153, figs. 3).—Brief notes on the changes which the digging feet of the mole cricket undergo during its development from the larval to the adult form.

A review of the North American species of *Athysanus*, H. OSBORN and E. D. BALL (*Ohio Nat.*, 2 (1902), No. 6, pp. 231-256, pls. 2).—The authors have excluded a number of species which had previously been referred to this genus and now admit 26 species, all of which are described, together with notes on their habitat.

The butterflies of the vicinity of New York City, W. BEUTENMÜLLER (*Jour. Amer. Mus. Nat. Hist.*, 2 (1902), No. 5, Sup. (Guide Leaflet No. 7), pp. 52, figs. 96).—Brief notes are given on the occurrence and feeding habits of nearly 100 species of butterflies which occur within a radius of 50 miles from the city of New York.

A natural history of the British Lepidoptera, III, J. W. TUTT (*London: Swan, Sonnenschein & Co.*, 1902, pp. XII+558).—This volume continues the author's text-book on the subject of British Lepidoptera, and contains a detailed account of the Sphingidae belonging to the group which the author names the *Sphingo-micropterygid stirps*. As in previous volumes, the synonymy of each species is given in great detail and extensive notes presented on the biology of the different species. The volume is furnished with numerous bibliographical notes and with a complete index.

Some plants which live upon and in insects, J. L. SHELDON (*Nebraska State Bd. Agr. Rpt. 1901*, pp. 131-141, figs. 11).—This paper is occupied with a discussion of bacteria and fungus diseases which have been found more or less useful in controlling insect pests.

The common spiders of the United States, J. H. EMERTON (*Boston: Ginn & Co.*, 1902, pp. 225, figs. 501).—The purpose of this volume is to present an account of the common species of spiders which will enable the ordinary observer to identify them and learn something of their habits and economic relations. The author discusses the anatomy and habits of spiders in general and gives a special account of a number of families of spiders, including Drassidae, Dysderidae, Thomisidae, Attidae, Lycosidae, Agelenidae, Therididae, Linyphiidae, Epeiridae, and Cniflonidae.

A short description of the Culicidæ of India, with descriptions of new species of *Anopheles*, F. V. THEOBALD (*Proc. Roy. Soc. [London]*, 69 (1902), No. 456, pp. 367-394, pl. 1, figs. 2).—In this report on the mosquitoes of India the author briefly describes the known species, together with a number of new ones, and presents a table for use in the identification of all species.

Observations on the larvæ of *Anopheles* and *Culex* in winter, B. GALLI VALERIO and G. ROCHAZ (*Centbl. Bakt. u. Par.*, 1. Abt., 32 (1902), No. 8-9, Orig., pp. 601-608).—The authors repeatedly found recently hatched and older larvæ of mosquitoes in pools and swamps throughout the winter season. Experiments made in the laboratory on the resistance of eggs of *Culex* to various physical and mechanical agencies indicate a considerable degree of resistance to these agencies. It is believed, therefore, that the eggs of mosquitoes may hatch during the warm days of winter, even under dry conditions. Subjection of eggs for 22 hours to a temperature of 0 C. had no effect in preventing the subsequent hatching. The same results were obtained from placing eggs on ice for 48 hours. It was found that under laboratory conditions the eggs are readily hatched when barely moist or while quite dry.

Reports on plans for the extermination of mosquitoes on the north shore of Long Island between Hempstead Harbor and Cold Spring Harbor, W. T. COX, H. C. WEEKS, ET AL. (*New York: North Shore Improvement Association, 1902*, pp. 125, figs. 8, map 1).—In the present volume the report is made on a survey of the northern

shore of Long Island for the purpose of locating the breeding grounds of mosquitoes and suggesting methods for destroying them. Popular notes are given on the habits and life history of mosquitoes by F. E. Lutz and C. B. Davenport. As the result of the survey of this region, recommendations are made concerning the methods of treatment of the various pools and bodies of stagnant water in which *Culex* and *Anopheles* were found to breed. It is believed by the authors that mosquitoes are not carried by their own flight or by the action of the wind to any great distance from their breeding ground. The north side of the island is thought, therefore, not to become infested by mosquitoes from the southern shore. A report was made by N. S. Shaler on the origin and present condition of the marshes and swamps of northern Long Island.

Notes on species of sand fly, W. R. COLLEDGE (*Proc. Roy. Soc. Queensland*, 17 (1902), No. 1, pp. 17-24, pls. 4).—Detailed notes are given on the appearance, habits, and life history of a species of sand fly which is believed to be closely related to *Ceratopogon albopunctus*. The insect is described in its various stages and notes are given on the difference in the habits of the 2 sexes. Apparently only the females attack man and domesticated animals.

The horse bot fly, C. FRESCH and J. R. WEIR (*Jour. Dept. Agr. Victoria*, 1 (1902), No. 7, pp. 693-697, pl. 1).—Notes are given on the habits and life history of *Gastrophilus equi*. Mention is made of the usual remedies adopted in preventing or curing infestation with the larvæ of this insect.

The influence of feeding cane sugar and starch sirup on the composition of honey, E. VON RAUMER (*Ztschr. Analyt. Chem.*, 41 (1902), No. 6, pp. 333-350).—Experiments were conducted by the author for the purpose of determining the extent to which the ferment of the honey stomach of the bee acts as an inverting or hydrolyzing agent on cane sugar and dextrin. During the feeding experiments the total amount of carbohydrates fed to the bees amounted to 1,336 gm., while the total amount of honey collected was 1,769.92 gm. Of the 456 gm. of cane sugar fed to the bees only 16.9 gm. were found in the honey, while of the 532 gm. of dextrin which was fed, 249.98 gm. were recovered in the honey. It is considered quite a remarkable fact that so small a quantity of cane sugar remained uninverted, while in previous feeding experiments a much larger percentage had passed over into the honey.

The long-tongued bees (Apidæ) of California, C. FOWLER (*California Sta. Rpt.* 1899-1901, pt. 2, pp. 316-330).—The author gives brief notes on the occurrence and distribution of the long-tongued bees of California. The notes are based largely on material which was collected near Berkeley in 1898. A number of new species were found in this collection and have been described elsewhere.

Studies on the organism of foul brood of bees, U. LAMBOTTE (*Ann. Inst. Pasteur*, 16 (1902), No. 9, pp. 694-707).—The author conducted a series of experiments with material obtained from various infested colonies of bees in different localities. As the result of extensive bacteriological study it is concluded that the so-called *Bacillus alvei* is not a distinct species but is identical with *B. mesentericus vulgaris*. This organism is an exceedingly common species and forms spores in the manner which had already been observed in the bodies of bee larvæ affected with foul brood. Inoculation experiments with healthy bees demonstrated that all the symptoms of foul brood could be produced by pure cultures of *B. mesentericus vulgaris*. Upon making a comparison of cultures of organisms obtained from bees affected with foul brood and of authentic cultures of *B. mesentericus vulgaris*, the 2 organisms were found to agree in every respect.

Silks of the Far East and French colonies; silkworms and related species, H. J. DE CORMEY (*Les soies dans l'extrême Orient et dans les Colonies Françaises; les vers à soie et leurs similaires*. Paris: Augustin Challamel, 1902, pp. 112, pl. 1).—The author presents a general account of the silk industry and discusses the present conditions of this business in China, Japan, India, Indo-China, Madagascar, Western Africa,

Algeria, and Tunis. In this discussion the author gives attention to a large number of species of insects from which silk has been produced. The species discussed belong to the genera *Antheraea*, *Attacus*, *Bombyx*, *Caligula*, *Saturnia*, *Sericaria*, etc.

FOODS—NUTRITION.

The influence of preservatives upon the food value of milk, C. F. DOANE and T. M. PRICE (*Maryland Sta. Bul. 86, pp. 64*).—Using the experimental methods described in a previous publication (*E. S. R.*, 13, p. 674), the authors quote a number of experiments with calves in which the digestibility of milk with and without added preservatives was tested. The preservatives used were boric acid, borax, salicylic acid, and formaldehyde, the boric acid and the salicylic acid being added to the milk in the proportion of 1:1,000, the borax in the proportion of 1:375, and the formaldehyde 1:10,000, it being recognized that all these amounts are in excess of the quantities usually regarded as sufficient. The average results of the experiments, which extend over 2 years, follow:

Average digestibility by calves of milk with and without preservatives.

Kind of preservative.	Protein.	Fat.
	<i>Percent.</i>	<i>Percent.</i>
Salicylic acid (added just before feeding)	98.02	93.96
Boric acid (added just before feeding)	93.84	97.16
Formaldehyde (added just before feeding)	95.01	97.75
Boric acid (added 24 hours before feeding)	91.00	97.57
Borax (added 24 hours before feeding)	92.22	97.35
Formaldehyde (added 24 hours before feeding)	94.83	98.36
Salicylic acid (added 24 hours before feeding)	90.04	92.81
No preservative	93.52	97.37

From these figures it appears that on an average 1.31 per cent more protein and 0.99 per cent more fat were digested when the milk was preserved with formaldehyde than when no preservative was added. In the case of salicylic acid there was a difference of 3.48 per cent protein and 4.56 per cent fat in favor of the untreated milk. With borax and with boric acid the difference was also in favor of the untreated milk, being for the borax 1.3 per cent protein and 0.02 per cent fat, and for the boric acid 2.52 per cent protein and 0.19 per cent fat.

"In all of the series the comparative results were nearly the same and the results in the 2 seasons' work were so nearly the same that it would appear that the work was exhaustive and could be depended upon to represent fairly well the results that would be obtained if this same line of work was carried on indefinitely. The results obtained in our work are practically the same as obtained by other workers. Borax and boric acid in the experiments conducted by other men appeared to slightly prevent digestion, while formaldehyde had the opposite effect.

"From the results of this work many people may be inclined to think that milk preserved with formaldehyde is even to be preferred to milk treated with no preservative, as the tables evidently show it to be more digestible. . . . But it would be entirely possible for the preservative to render the milk more digestible and still have properties that would prove injurious. It is entirely possible for the preservative to unduly stimulate the digestive organs and in the course of time bring them to a diseased condition. For this reason it is impossible to say that formaldehyde, if injurious, is the least injurious of any of the preservatives used in the milk business. The fact that the other preservatives used made the milk less digestible is sufficient to condemn them. Adults could possibly drink such milk with impunity, but in the tenement districts of cities, where the babies have a hard struggle for existence, it takes a very little to turn the scale either in favor or against their chances for life."

The average gain in weight per calf during the 3-day periods in which milk with boric acid was fed was 0.5 lb., milk with salicylic acid 3 lbs., with formaldehyde 5 lbs., and milk with no preservative 1 lb.

"The calves fed for an extended period with milk preserved with boric acid and formaldehyde made very satisfactory gains in weight. The two receiving the boric acid lost a good share of their hair, presumably from the effects of the acid."

The effect of curdling with rennet upon the digestibility of milk, R. POPPER (*Arch. Physiol. [Pflüger]*, 92 (1902), No. 10-12, pp. 605-614).—Artificial digestion experiments showed that milk coagulated with rennet was somewhat less digestible than untreated milk, but the author believes that the difference is not as marked as has been claimed by some other investigators, since he found that there was a considerable range in the results of parallel experiments.

The digestibility of food consumed with varying quantities of water, S. RŮŽIČKA (*Arch. Hyg.*, 45 (1902), No. 4, pp. 409-416).—The author was himself the subject of experiments in which the digestibility of a mixed ration was determined when a fairly large quantity of water was consumed at intervals during the day and when practically the same amount was consumed immediately before, during, and after meals. In each case the amount of water consumed daily was practically the same, averaging nearly 1,480 gm. daily. The results obtained showed that the mixed diet was somewhat more thoroughly digested when the bulk of the water was taken near meal times. The author believes that the results are not numerous enough for general deductions, but that they do warrant the conclusion that a reasonable amount of fluid taken at meal times can not have any bad effect.

The digestibility of foods and condiments as shown by microscopical studies of the feces, F. SCHILLING (*Die Verdaulichkeit der Nahrungs- und Genussmittel auf Grund mikroskopischer Untersuchungen der Faeces*. Leipzig: H. Hartung & Son, 1901, pp. 132, figs. 102).—Believing that the digestibility of different materials can be most accurately determined by a microscopical examination of the undigested residues, the author describes methods and reports results of a large number of such investigations. Some of the general conclusions follow: All foods which are not soluble in water or rendered soluble by the digestive juices give larger or smaller amounts of undigested residue. An abundant vegetable diet hinders the digestibility of animal foods. There are no large undigested fragments from raw, finely chopped loin of beef. When it is eaten with black bread large muscle fibers are found in the feces together with rye hulls. Vegetable foods furnish the greater part of the feces. When a mixed diet is eaten isolated starch cells are always found in the feces and distended starch cells are regularly found, derived from the endosperm or the interior of cereals, potatoes, and legumes, even if these materials were finely ground or otherwise finely divided. The method of cooking, the mechanical condition of food, habit, and regularity in eating are of the greatest importance in the digestion of food and hence for the nutritive value of different materials under normal conditions. Undigested residue from a given diet is generally excreted on the second day after the food is eaten. Mechanical stimulation of peristaltic action is less important than thermic and chemical stimulation.

On the causes, variations, and significance of the color of the feces, L. A. CONNER (*Med. News, New York*, 81 (1902), No. 9, pp. 400-403; *abs. in Jour. Amer. Chem. Soc.*, 24 (1902), No. 11, p. 500).—The color of normal feces of adults on a mixed diet is a brown of varying degrees of darkness. This color, while due in large measure to the presence of modified bile pigment, is the result of a number of causes. The elements which go to make up the color may be grouped as follows: (1) Digestive secretions, (2) food residues, (3) discharges from the intestinal mucous membrane, and (4) accidental ingredients, such as drugs, etc.

Observations on vegetable proteolytic enzymes, with special reference to papain, L. B. MENDEL (*Amer. Jour. Med. Sci.*, 124 (1902), pp. 310-318).—The

experiments which are reported on the character of the proteolytic action of papain led to the following conclusions: "While the products of the papain digestion of proteids resemble quite closely those of pepsin, so far as they have been examined in detail, the enzym differs from ordinary animal pepsin in that it acts readily in both neutral and alkaline media. On the other hand, although papain is comparable with trypsin in exerting a solvent action in fluids of various reactions, the failure to form leucin, tyrosin, or tryptophan in inappreciable quantities—at least under conditions in which they are readily formed in large quantities by the other tryptic enzymes—places it in a class of its own for the present."

A new method of measuring the effect of pepsin, E. I. SPRIGGS (*Ztschr. Physiol. Chem.*, 35 (1902), No. 6, pp. 465-494, pls. 2, figs. 8).—From experimental data which are reported, the author believes that a study of the viscosity of solutions treated with pepsin furnishes a means of judging of its effects. His conclusions follow: The viscosity of a solution of coagulable protein diminishes during the process of digestion. A similar effect is observed when hydrochloric acid is present without the pepsin, but it takes place much more slowly. If the change in viscosity during digestion is shown graphically as a curve, it will be seen that the change is at first rapid, then slower, and finally very small. When the viscosity remains constant the greater part of the coagulable protein is transformed into the uncoagulable form. Portions of the same protein solution treated with different quantities of pepsin contain like amounts of coagulable and uncoagulable protein when the viscosity is the same. The decrease in viscosity shown by curves can be explained mathematically, and furnishes a means of measuring the rapidity of digestion of different pepsin solutions.

The effect of different chemical bodies upon the activity of pancreas diastase ferment, P. GRÜTZNER (*Arch. Physiol. [Pflüger]*, 91 (1902), No. 3-4, pp. 195-207, figs. 3).—The chemical bodies included in these experiments, which were conducted by M. Wachsmann, were halogen salts, alkalis and alkali salts, sulphates and other salts, inorganic and organic acids, alcohol, and chloroform.

Concerning the process of digestion in the small intestine, II, F. KUTSCHER and J. SEEMANN (*Ztschr. Physiol. Chem.*, 35 (1902), No. 4-5, pp. 432-458).—A study of the ferments of the small intestine.

Concerning the absorption of simple stereoisomeric sugars in the small intestine, J. NAGANO (*Arch. Physiol. [Pflüger]*, 90 (1902), No. 7-8, pp. 389-404, fig. 1).—Using dogs with fistulas the author studied the absorption of 4 hexoses, i. e., d-glucose, d-galactose, d-mannose, and d-fructose, and 2 pentoses, i. e., l-xylose and l-arabinose. It was found that the stereoisomeric sugars had a different rate of absorption. Sugars with 5 carbon atoms were more slowly absorbed than those with 6 carbon atoms. When sugar solutions of like concentration were taken, the water absorption showed the same differences in rapidity as the sugars. The absorption of water diminished in proportion to concentration of a given sugar solution. In the upper part of the intestine, relatively speaking, sugar is more rapidly absorbed than water; in the lower part of the intestine the reverse is true.

On the lymphagogic action of the strawberry, and on post-mortem lymph flow, L. B. MENDEL and D. R. HOOKER (*Amer. Jour. Physiol.*, 7 (1902), No. 4, pp. 380-386).—In experiments made with a dog, an extract prepared from desiccated strawberries was injected intravenously. According to the author, this accelerates the flow of lymph richer in solids than is normally the case, and its action resembles that produced by other typical lymphagogues of Heidenhain's first class, viz, those which produce their particular lymphagogic influence by stimulating the endothelial cells of the blood capillaries, and that the latter thus exert a secretory function which results in the formation of lymph. The effect of strawberry extract on the post-mortem flow of lymph was also studied.

Concerning the formation of sugar from protein, O. LOEW (*Beitr. Chem.*

Physiol. u. Pathol. Ztschr. Biochem., 1 (1902), pp. 567-574; *abs. in Ztschr. Untersuch. Nahr. u. Genussmittel*, 5 (1902), No. 20, p. 973).—A theoretical discussion of the way in which sugar may be formed from protein in the body.

The formation of sugar from fat, O. LOEWI (*Arch. Exper. Path. u. Pharmacol.*, 47 (1902), pp. 68-76; *abs. in Ztschr. Untersuch. Nahr. u. Genussmittel*, 5 (1902), No. 20, pp. 973, 974).—According to the author, the experiment which he made with a dog did not supply any basis for the belief that sugar is formed from fat.

Note on the nature of the flour produced in the gradual reduction of wheat, F. B. GUTHRIE and G. W. NORRIS (*Agr. Gaz. New South Wales*, 13 (1902), No. 9, pp. 936-939).—Statistics are given of the amount of different milling products obtained from a number of varieties of wheat, and also of the percentage of flour, its strength and gluten content. According to the author, "the quantity of gluten obtained increases steadily with each successive break—that is to say, as the flour is obtained from the neighborhood of the bran. In the last break, in which the bran is scraped as close as possible, the flour is extraordinarily rich in gluten, and is derived entirely from the so-called aleurone layer, and it is just this layer that supplies the bulk of the gluten. This richness in gluten is, unfortunately, not accompanied with the other characteristics which go to make a good flour, and the flour from the last break is of little value on account of its low color."

Reports upon food and drug inspection for the year ending September 30, 1901, A. E. LEACH (*Massachusetts State Bd. Health Rpt. 1901*, pp. 59).—Analyses of cocoa, lemon and vanilla extracts, milk, condensed milk, lime juice, and cider vinegar are reported; and methods are given for the estimation of milk sugar in milk, as well as rapid routine methods for the detection of preservatives and for approximating the quality of milk, tables useful for the calculation of results being included. The latter methods, it is believed, are suited to the needs of milkmen. Of the 6,109 samples of milk examined, 28.4 per cent were found to be adulterated. The total number of foods other than milk examined was 3,120, and the percentage of adulteration was 18.9.

Second report on food products for 1901, B. W. KILGORE (*Bul. North Carolina State Bd. Agr.*, 23 (1902), No. 9, pp. 70, figs. 7).—The results obtained in carrying out the provisions of the State pure-food law are summarized and discussed, and several special articles, which discuss methods of analyses and give results of examinations of food products, are reported, including Baking Powders, by W. M. Allen and F. C. Lamb; Tea, by C. D. Harris; Coffee, by C. D. Harris; Sugar, by W. M. Allen; Molasses, Sirups, and Honey, by J. M. Pickel, W. G. Haywood, and F. C. Lamb; Jellies, by W. M. Allen, W. G. Haywood, and F. C. Lamb; Jams, Fruit Butters, and Preserves, by W. M. Allen, W. G. Haywood, and F. C. Lamb; Vinegar, by W. M. Allen, and Condiments, by J. M. Pickel.

Adulteration of food (*Report, Returns, and Statistics of the Inland Revenues of the Dominion of Canada for 1902*, pt. 3, pp. 133).—In the reports of the official analysts of different districts and in the appendixes a number of analyses are reported of tea, milk, coffee, cocoa and chocolate, cheese, etc., most of which were made with the general purpose of detecting adulteration or sophistication. Bulletins No. 79 on Oil of Turpentine, No. 80 on Milk, and No. 81 on Fertilizers, are included in this report among the appendixes.

Dietaries for hospitals for the insane, W. O. ATWATER (*New York State Lunacy Com. Rpt. 1900-1901*, pp. 39-322).—Continuing earlier work (*E. S. R.*, 12, p. 877), the author reports the results of 16 dietary studies made in New York State institutions for the insane. The results are discussed with a view to improving the diet and making it more in accord with physiological standards. It was found that on an average the food actually eaten supplied 73 gm. protein and 2,305 calories of energy per person per day. The author's proposed dietary standard for inmates of institutions like those studied calls for 85 gm. of protein and 2,500 calories of energy per

person per day, as the fact is recognized that the diet should be adequate to support the body without any danger of underfeeding. Valuable features of this article are tables showing the quantities of different food materials approximately equivalent in nutritive value to 100 pounds of a given material taken as a standard, and recipes for the preparation of a number of palatable and attractive dishes, some of which are comparatively inexpensive.

In Danish and Russian old-age homes, EDITH SELLERS (*Living Age* [Littell], 7. ser., 17 (1902), No. 3046, pp. 473-482).—In this article, which is reprinted from *The Nineteenth Century and After*, the homes provided for aged people in Denmark and Russia are described. In the former country the homes are maintained at public expense; in the latter very largely by private funds. The diet, especially in relation to its cost, is treated of at some length as well as other special topics.

Recent contributions to the subject of the examination and valuation of commercial food alimentary pastes, A. JUCKENACK and R. SENDTNER (*Ztschr. Untersuch. Nahr. u. Genussmittel*, 5 (1902), No. 21, pp. 997-1018).—Methods of examining noodles and other similar pastes are described.

Cocoanut butter, P. POLLATSCHKE (*Chem. Rev. Fett u. Harz-Ind.*, 9 (1902), pp. 4, 5, 28, 29; *abs. in Ztschr. Untersuch. Nahr. u. Genussmittel*, 5 (1902), No. 22, pp. 1136, 1137).—The manufacture and uses of cocoanut butter and similar products made from cocoanut oil are described.

Household economics, HELEN S. CAMPBELL (*New York and London: G. P. Putnam's Sons*, 1902, pp. XXI + 286).—This volume comprises a course of lectures delivered in the School of Economics of the University of Wisconsin. Chapters are included on the nutrition of the household, food and its preparation, cleaning and its processes, and household service, as well as upon subjects concerning the building and furnishing of the house, and related topics. In the appendix the author discusses the teaching of household economics and quotes material illustrating the way in which this subject or some of its branches has been taught at different institutions.

Practical cooking and serving, JANET MCK. HILL (*New York: Doubleday, Page & Co.*, 1902, pp. XIX + 731, pls. 74, figs. 6).—In addition to a large number of recipes for preparing various simple and elaborate dishes, the author discusses the functions and uses of food, marketing, garnishing and serving, and related topics.

Harper's cookbook encyclopædia (*New York: Harper & Bros.*, 1902, pp. 443, pl. 1).—This volume, in which the subject-matter is arranged as in a dictionary, contains recipes and other material contributed by a number of different authors.

Foods and food control, W. D. BIGELOW (*U. S. Dept. Agr., Bureau of Chemistry Bul.* 69, pls. 1, pp. 1-94; 2, pp. 95-188; 3, pp. 189-272; 4, pp. 273-372; 5, pp. 373-461).—A compilation of the United States Federal and State laws regarding the manufacture and sale of foods and food products with special reference to adulteration and sophistication.

ANIMAL PRODUCTION.

Commercial feeding stuffs in Pennsylvania, W. FREAR (*Pennsylvania Sta. Rpt.* 1901, pp. 28-109).—The composition and feeding value of several different classes of feeding stuffs are discussed, in many cases the process of manufacture being described. A number of analyses of feeding stuffs are reported, including cotton-seed meal, linseed meal (old and new process), wheat (whole grain, bran, middlings, shorts, shipstuff, flour, and red dog flour), wheat feeds, rye, chop and middlings, malt sprouts, ground oats, oat feeds, corn, cracked corn, corn chop, corn-and-cob chop, gluten feeds and meals, germ oil cake, corn bran, sugar feeds, sugar-corn feeds, hominy chop, cerealine feeds, buckwheat flour and middlings, commercial breakfast food by-products, mixed feeds, poultry feeds, and condimental feeds.

Miscellaneous cattle food analyses, W. FREAR (*Pennsylvania Sta. Rpt. 1901*, pp. 110-116).—In addition to the analyses reported above, the station has analyzed a number of feeding stuffs submitted by individuals, the analyses, it is stated, in a number of cases being incomplete. The feeding stuffs include cotton-seed meal, flax-seed meal, linseed meal (old and new process), wheat bran, wheat feed, corn meal, steam cooked corn-meal feed, gluten feed, corn bran, hominy feed, cerealine feeds, oat feed, buckwheat middlings, buckwheat feed, cocoanut meal, dried brewers' grains, dried distillery feed, sugar-beet feed, dog meal, meat scrap, cereal breakfast food by-products, and mixed feeds.

The by-products obtained in grinding wheat and rye, F. OTTO (*Inaug. Diss., Göttingen, 1901; abs. in Centbl. Agr. Chem., 31 (1902), No. 9, pp. 606-610*).—A comparison was made of the German and imported rye and wheat, the composition of different varieties of these grains and their milling products being reported, as well as results of digestion experiments made with sheep.

The purchase of feeding stuffs (*Bd. Agr. [London], Leaflet 74, pp. 1-12*).—A popular discussion of the principles of nutrition and the different classes of feeding stuffs.

Report on molasses feeds, C. V. GAROLA (*Compt. Rend. Cong. Soc. Aliment. Nat. Bdt., 6 (1902), pp. 1-15, dgms. 3*).—Mixtures of molasses with peat, peanut hulls, sesame and peanut hulls, and with straw were described and the favorable results obtained in feeding such mixtures to sheep and horses briefly noted. The rations containing the molasses mixtures were cheaper than those made of more common feeding stuffs.

The influence of lecithin on the development of the skeleton and nerve tissue, A. DESGREZ and A. ZAKY (*Compt. Rend. Acad. Sci. Paris, 134 (1902), No. 20, pp. 1166-1168*).—From experiments with Guinea pigs, rabbits, and dogs the conclusion is drawn that feeding lecithin rendered the food more effective, especially in the formation of the skeleton and nervous system.

Study of the way in which lecithin acts in the animal body, A. DESGREZ and A. ZAKY (*Compt. Rend. Cong. Soc. Acad. Sci. Paris, 134 (1902), No. 25, pp. 1522, 1523*).—Experiments, which are briefly reported, made with guinea pigs led to the conclusion that the favorable effects which were observed to follow the feeding of lecithin were not due to glycerophosphoric acid (the acid radical of lecithin), but to the basic portion. It was found that cholin and betain exercised a favorable effect, though in a less degree than lecithin, upon the formation of nitrogenous tissue and gains in weight.

Concerning the metabolism of growing dogs, E. ROST (*Arb. K. Gesundheitsamte, 18 (1901), No. 2, pp. 206-218, pl. 1*).—From experiments reported in detail the conclusion is drawn that the amount of nitrogen retained was greater than could be accounted for by the gain in body weight.

Methods of steer feeding, G. C. WATSON and A. K. RISSE (*Pennsylvania Sta. Rpt. 1901, pp. 211-222*).—The comparative merits of fattening steers in pens and stalls was studied in continuation of previous work (*E. S. R., 12, p. 875*), the State department of agriculture cooperating with the Pennsylvania Station. Of the 2 tests reported the first was made with 3 lots, lot 1 containing 10 animals and lots 2 and 3 containing 6 each. The steers in lot 1 occupied a box stall having a space equivalent to that of 10 ordinary stalls. Each of the animals in lots 2 and 3 was kept in a separate stall. Lots 1 and 2 were supplied with water by means of an automatic basin and lot 3 was watered daily in a yard, as it was desired to test the merits of different methods of watering as well as other points which have to do with the comparative amount of labor required to care for steers fattened under different conditions. All of the animals were fed a grain ration consisting of corn meal and wheat bran, 9:1, in addition to hay and corn stover. At the beginning of the test the average weight of the steers was not far from 950 lbs. each. During the 14 weeks

of the trial the average daily gains per head in the 3 lots were 2.05 lbs., 2.18 lbs., and 1.89 lbs. The steers in lot 1 consumed per pound of gain 3.63 lbs. hay, 1.46 lbs. stover, and 8.39 lbs. grain. Similar values for lot 2 were 3.21, 0.94, and 7.82 lbs., and for lot 3 they were 3.47, 0.79, and 8.39 lbs., respectively. The time expended in the care of the 3 lots was 79.6, 148, and 155.5 hours, respectively, the values for lots 2 and 3 being recalculated on a basis of 10 animals per lot.

In a second test, made under practically the same conditions, with 3 lots of 2 steers each, the average weight of the animals at the beginning was about 890 lbs. and the average daily gain per steer in the different lots during the 57 days of the trial 2.71, 2.92, and 2.7 lbs., respectively. The hay eaten per pound of gain in the 3 lots was 4.44, 3.76, and 3.45 lbs., and the grain 5.91, 5.24, and 4.95 lbs., respectively.

According to the authors the results of this and their former work did not justify the claim that either of the methods tested was superior for fattening steers.

"Those animals that were furnished water by means of automatic watering basins consumed more coarse fodder, particularly stover, and ate their food with apparently greater relish, than did those that were turned out in a yard to water. The steers that were loose in a box stall or pen required less labor of attendance than those that were confined in stalls, even though both were supplied with water by means of automatic watering basins. The steers that were confined in a box stall required the same amount of bedding as those confined in stalls."

Cattle feeding with sugar beets, sugar, molasses, and sugar-beet residuum, L. S. WARE (*Philadelphia: Philadelphia Book Co., 1902, pp. XXIII + 389, figs. 21*).—In this volume the author has discussed the feeding value of sugar beets and sugar-beet products, the methods of pressing and drying beet pulp, the manufacture of molasses feeds, and related topics, quoting extensively from the literature of the subject and summarizing the results of American and foreign experiments. A detailed index adds to the value of the volume.

The business of breeding pure-bred stock, J. A. CRAIG (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901, pp. 416-432*).—A general discussion of the subject of breeds and breeding, emphasizing its importance from a business standpoint.

Breeds of beef cattle and beef production in North Carolina, T. BUTLER (*Bul. North Carolina State Bd. Agr., 23 (1902), No. 7, pp. 53, figs. 39*).—The characteristics of different breeds of beef cattle are discussed, as well as such subjects as the formation of a herd, pastures, feeding and care, and related topics.

The cattle industry of the United States, J. WILSON (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901, pp. 267-274*).—In this paper, which was read before a meeting of the Central Shorthorn Breeders' Association in Kansas City, the Secretary of Agriculture discusses the importance of the export cattle trade of the United States with special reference to Mexico and South America. The need of stringent laws regarding the inspection of cattle imported to this country is insisted upon, and the fact is pointed out that it is equally important to export only healthy cattle of superior quality if the enterprise is to be developed along the most satisfactory lines.

Cattle markets and abattoirs in Europe, H. E. ALVORD (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901, pp. 279-305, pls. 9, map 1*).—A descriptive and statistical article, dealing with the handling and slaughtering of live stock, inspection of meat, and related topics.

History of the farm-animal industry of Westphalia and methods of increasing it, J. KLEINSORGE (*Inaug. Diss., Univ. Jena, 1902, pp. 48, maps 2*).—A critical discussion of statistical and historical data.

The musk ox, G. F. THOMPSON (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901, pp. 507-512, pls. 2, fig. 1*).—A descriptive article.

Some observations on sheep breeding from the experiment station flock records, W. L. CARLYLE and T. F. MCCONNELL (*Wisconsin Sta. Bul. 95, pp. 19*).—For

12 or more years the station has kept a record of sheep-breeding operations. For the first years this included only the ear-tag number of the service ram and ewes, the date of service, and the date of birth of the lambs. "The record was gradually perfected until during the past four years it included the number of lambs dropped and their sex, the weight and condition of lambs at birth, the apparent milking qualities of the ewes, and the weights of the ewes and the service rams used."

The general deductions drawn from the recorded data follow:

"From the breeding records of 514 ewes at this station we conclude that for such animals and conditions as ours the normal period of gestation ranges from 144 to 150 days after the date of service, and that more ewes will lamb 146 days after service than at any other time.

"There is no appreciable difference in the period of gestation for male and female offspring in sheep. There is an apparent relation between the duration of the period of gestation and the period required for reaching maturity. Quick-maturing breeds appear to carry their young for a shorter period than those breeds requiring more time to mature. Large lambs are on the average carried *in utero* for an appreciably longer period than small or medium lambs. Lambs dropped before the 144th and after the 149th day of pregnancy are lacking in strength and vitality at birth.

"Shropshire ewes were more prolific than any of the other breeds and crosses except the fourth cross of Shropshire rams on a Merino ewe foundation. From the data presented it is apparent that twins are the normal increase for ewes of the mutton type.

"One-year-old rams are not so prolific as those 2 or 3 years old. Ewes also average a larger percentage of increase in lambs after they reach full maturity at 3 years of age until after they are 6 years old, when the rate of increase diminishes. The amount of service required of the ram in breeding has an influence on the percentage increase in offspring of the ewes that produce lambs. Ewes bred early in the season of mating to a single ram dropped a larger percentage of lambs than those near the latter end of the season."

The maintenance ration of sheep, W. W. COOKE (*Pennsylvania Sta. Rpt. 1901, pp. 238-294*).—Cooperating with the State department of agriculture, a number of experiments were conducted to learn the amounts required by sheep for maintenance, on a ration of timothy hay alone, and of timothy hay and corn in the proportion of 2:1 and 1:2. The total weight of the feed in the 3 cases, which it was estimated would suffice for sheep weighing 50 kg., was 1.21 kg., 1.06 kg., and 0.94 kg., respectively. These values are based on a deduction from experiments with steers, that 11 lbs. digestible nutrients from corn is equivalent to 13 lbs. digestible nutrients from timothy hay. The estimated amounts proved to be very nearly correct. Sheep 1 and 2, each weighing not far from 50 kg. at the beginning of the trial, were fed the full amounts mentioned. Sheep 3, weighing not far from 30 kg., was fed 70 per cent of the amounts given the other sheep, as it was estimated that the surface area of this animal was 70 per cent of that of a sheep weighing 50 kg.

The feeding periods were of 10 days' duration. The sheep were kept in specially constructed crates, with devices for conveniently collecting the excreta. The food and excretory products were in every case weighed and analyzed. On an average the 3 rations were found to have the following coefficients of digestibility:

Average coefficients of digestibility—Experiments with sheep.

Ration.	Dry matter.	Organic matter.	Protein.	Non-nitrogenous material.	Ash.	Energy.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Timothy hay alone	58.8	59.3	40.0	60.6	49.7	54.2
Timothy hay and corn, 2:1	65.5	66.3	46.5	68.1	43.9	61.4
Timothy hay and corn, 1:2	72.8	73.9	56.4	75.8	37.0	70.1

That the rations were practically sufficient for maintenance is shown by the small variation in live weight during the 79 days covered by the actual experimental and intervening periods and also by the figures for the gain or loss of nitrogen. These values have been summarized in the table which follows:

Average gain or loss of nitrogen and live weight.

	Sheep 1.	Sheep 2.	Sheep 3.
	<i>Grams.</i>	<i>Grams.</i>	<i>Grams.</i>
Average daily gain or loss of nitrogen	-0.17	+0.17	+0.07
Nitrogen in daily growth of wool64	.64	.48
Average daily gain or loss of nitrogen of flesh	-.81	-.47	-.41
Average daily gain or loss of live weight	-1	+13	-8

"The above figures show that if it is considered that there was no change in the average body fat of the animals during the test, the assumption [that the rations were sufficient] can not be far from the truth."

The author's summary of the digestible protein and non-nitrogenous material furnished by the rations which, as already stated, were considered as sufficient for maintenance follows:

Summary of maintenance rations.

	Sheep 1 and 2. Average weight, 46.4 kg.	Sheep 3.	
		Actual weight, 29.2 kg.	Calculated for weight of 46.4 kg.
	<i>Grams.</i>	<i>Grams.</i>	<i>Grams.</i>
Hay alone:			
Digestible protein	32.7	20.6	28.2
Digestible non-nitrogenous matter	479.8	385.8	556.8
Total digestible organic matter	502.5	406.4	585.0
Hay and corn (2:1):			
Digestible protein	34.5	23.6	32.3
Digestible non-nitrogenous matter	558.6	360	493.2
Total digestible organic matter	593.1	383.6	525.5
Hay and corn (1:2):			
Digestible protein	38.1	22.4	30.7
Digestible non-nitrogenous matter	535.7	334.4	458.1
Total digestible organic matter	573.8	356.8	488.8
Average:			
Digestible protein	35.1	22.2	30.4
Digestible non-nitrogenous matter	523.7	360.1	502.7
Total digestible organic matter	558.8	382.3	533.1
Nutritive ratio	1:15	1:16	1:16

From these figures the author concludes that a sheep requires for maintenance, per 50 kg. shorn weight, 37 gm. digestible protein and 538 gm. digestible nitrogen-free nutrients, the starch value of the ration being 596 gm. In discussing the maximum amount of protein required, he states that "when on hay alone, the 3 sheep received on the average 23.9 gm. of digestible protein. But it was not sufficient and the sheep drew on their bodies for 7.3 gm. more of protein, making the total needed by the body 31.2 gm. per day. When eating hay and one-third corn, they digested 32.4 gm. and had to call on their bodies for but 1.4 gm., a total of 33.8 gm. When given a liberal ration of hay and two-thirds corn, they found that 39.8 gm. of protein were more than they needed and they stored up 4.2 gm. in the body, leaving 35.6 gm. as the daily need of the system. These 3 sets of results are very close and while they show, as they ought to, that the animals were a little more

sparing of protein when the supply was short than when it was abundant, they also show that sheep can thrive on but little more than half the protein than has been usually considered advisable."

Making corrections for gain or loss of flesh, it was computed that on an average the sheep required 2,009.8 calories for maintenance on a basis of 46.4 kg. live weight exclusive of wool, which is equivalent to 2,096 calories per 50 kg. shorn weight. The author assumes that on an average 10.3 gm. of wool is produced per day and on a basis of chemical composition calculates that this amount has an energy value of 20.55 calories.

"As the maintenance ration of a sheep is approximately 2,000 calories per head per day, it will be seen from the above figures how small a draft is made for the growth of the wool. This also helps to explain the fact, that has been observed, that when the ration is insufficient for maintenance the growth of wool is but slightly reduced."

The requirements of sheep in proportion to weight and surface area are discussed, and the conclusion reached that "in proportion to its body surface the sheep is more economical of its food than the steer."

Throughout the test the amount of water consumed was recorded and it was found that the average amount drank per sheep per day on a hay ration was 1.57 kg. On hay and corn, 2 : 1, it was 1.29 kg., and 1.11 kg. on a ration of hay and corn, 1 : 2.

In connection with the above experiments some tests were made to determine the amounts of nitrogen and carbon lost in drying feces, and the chemical bodies in which the loss occurs. On an average the feces from hay alone lost 6.6 per cent of the nitrogen originally present. Those from hay and one-third grain 7 per cent; and from hay and two-thirds grain 7.3 per cent. These differences are so slight and the differences between duplicates are so great as to indicate that the amount of loss is not dependent on the kind of feed nor on the individuality of the sheep. The losses are probably dependent on the bulk of the material and the temperature to which it is exposed.

In one case it was found that 0.571 per cent of the final dry matter was lost as carbon and 0.390 per cent as nitrogen. According to the author "the common acids produced by the action of the ferments of the digestive canal are acetic and butyric acids. In one case the proportions were two parts of acetic to one of butyric acid. In most cases the proportions of butyric acid were less. . . . It is probable that in air-drying, sheep feces lose 1 per cent of their heat value in the form of ammonium acetate in addition to ammonium carbonate and an additional, though small, quantity in skatol and other volatile organic compounds. In estimating the energy value of the rations eaten in the accompanying digestion experiments no allowance has been made for this heat value lost in drying. It would diminish the amount of energy calculated for the daily maintenance ration by about 10 calories or 0.02 of its value."

The results obtained with carbon are not regarded as final, but are given as a progress report.

The energy of the urine and the losses in drying it were also studied. In one case it was found that the loss of carbon amounted to 0.269 per cent and that of nitrogen to 0.224 per cent. On the basis of these figures and other data the author calculates the proportion of these elements lost as ammonium carbonate and as indol and skatol. From a consideration of the available data he concludes that "instead of sheep urine being a mere solution of urea and hippuric acid, in this case fully half the total carbon probably existed in non-nitrogenous compounds. Other tests of sheep urine from different feeds have given widely varying results, showing that there is no constant relation of the nitrogenous and non-nitrogenous constituents."

Determinations of the heat of combustion of sheep urine and a consideration of the probable composition of the dried residue led to the conclusion that in estimating

the energy value of urine 32.3 calories should be allowed for each gram of nitrogen present in the fresh material.

A number of experiments were made in which the body of a sheep was inclosed in an air-tight box. The head protruded through an aperture, a loss of air being prevented by a large piece of rubber which fitted tightly around the neck and was attached to the box. Analyses of a current of air drawn through the box led the author to conclude that the amount of carbon dioxide excreted otherwise than in the respiratory products was very small, averaging about 0.02 of the total amount excreted per day from the lungs. Determinations of the methane in the ventilating current led to the deduction that "the amount of methane obtained as an excretion of the skin and intestines was small, amounting to about 2 gm. of methane per day."

Attempts to determine the amount of methane formed in the paunch were made with a sheep having a silver tube inserted in the trachea, through which gaseous products could be collected for analysis. The results obtained are not regarded by the author as satisfactory.

Lamb-feeding experiments, 1900-1902, B. C. BUFFUM and C. J. GRIFFITH (*Colorado Sta. Bul.* 75, pp. 36, pl. 1, figs. 5).—Three tests with lambs are reported. In the first, which covered 84 days, 4 lots of 5 Mexican lambs averaging 55 lbs. each were used. All were fed alfalfa hay ad libitum, lots 1 and 2 receiving sugar-beet pulp in addition, and lots 3 and 4 sugar beets. All the lambs were fed some corn until they became accustomed to the beet ration, and during the last 8 weeks of the test a mixture of wheat and barley, 1:1, replaced the pulp or beets in the ration of lots 2 and 4. Lot 1 (beet pulp) gained 76 lbs., lot 2 (beet pulp and grain) 94 lbs., lot 3 (sugar beets) 106 lbs., and lot 4 (sugar beets and grain) 121 lbs. Lots 1 and 3 each gained 16 lbs. in fleece and lots 2 and 4 gained 17 lbs. The average cost of a pound of gain in the 4 lots was 2.83, 4.65, 4.16, and 4.87 cts., respectively. At the close of the test the lambs were slaughtered. The dressed weight of lots 1 and 2 was 45.7 and 48.1 per cent and of lots 3 and 4 it was 46.6 per cent of the live weight, respectively. The greatest profit, \$3.40, was realized with lot 1 (beet pulp), the lowest, \$2.17, with lot 2 (beet pulp and grain), the amounts for lots 3 and 4 being respectively \$2.88 and \$2.23.

Another lot of 5 Mexican lambs, which was fed a ration of beets and grain with straw instead of alfalfa, gained so little that it is not compared with the others and no values are reported.

The principal conclusions drawn from the test follow:

"Beet pulp is a valuable roughage to feed with alfalfa, and we believe would be especially valuable to use during the first part of a feeding period. Pulp-fed mutton had good flavor, but was not very fat.

"Beet pulp which does not cost the feeder more than \$1.50 per ton at his yards, will give a return sufficiently large to pay for using it in a ration, but we would not recommend letting lambs eat so much of it during the finishing period that they will not consume good rations of hay and grain.

"Sugar beets did not prove to have a high feeding value for lambs. It is doubtful if farmers can afford to feed beets to lambs if they can sell them to a factory at \$4.50 per ton, and the conditions must be favorable to make beets give a return sufficiently large to pay for raising them. Two pounds of sugar beets were equal to about one pound of pulp. Sugar beets and poor kinds of roughage can not be made to take the place of alfalfa hay."

The purpose of the second test was a comparison of home-grown grains with corn. Five lots of Mexican lambs, like those in the above test, were used, the lots being numbered 5 to 9, inclusive. They were all fed alfalfa hay ad libitum, and in addition lot 5 was fed corn, lot 6 spelt, lot 7 barley, lot 8 wheat and barley 1:1, and lot 9 wheat and spelt 1:1. With lots 5, 6, and 7 the feeding was continued for 90 days and with lots 8 and 9 for 95 days. The total gains in flesh in the 5 lots were 113, 127, 97, 117, and

87.5 lbs., the gains in fleece being 17, 15, 20, 14, and 14 lbs., respectively. The cost of a pound of gain in the 5 lots was 5.25, 4.28, 4.95, 4.68, and 5.93 cts., the alfalfa hay consumed per lb. of gain being 6.17, 6.26, 7.59, 6.50, and 8.20 lbs., and the grain 3.09, 3.03, 3.43, 3.38, and 4.28 lbs., respectively. The lambs were slaughtered at the close of the test, the dressed weight averaging 52.1, 49.2, 48.8, 49.6, and 59 per cent of the live weight, respectively. The profit ranged from 52 cts. in the case of lot 9 (wheat and spelt) to \$3.04 in the case of lot 6 (spelt), the values for lots 5, 7, and 8 being \$1.65, \$2.02, and \$2.30, respectively. According to the authors:

"These trials showed that at the same price corn had a feeding value greater than a mixture of wheat, barley, and oats, or wheat and barley, or barley alone.

"Our single trial with Russian spelt showed it to have a feeding value at least equal to corn, and greater than wheat and barley."

The relative merits of corn and home-grown grain were further tested with 4 lots of lambs. Lots 1, 2, and 4 contained 2 Shropshire crosses and 3 western lambs, and lot 3 contained 3 Shropshire crosses and 2 western lambs. All the lambs were fed alfalfa hay. In addition lots 1 and 2 were fed a mixture of equal parts of oats, wheat, and barley, and lots 3 and 4 corn. The drinking water given to lots 1 and 4 was cold and that given lots 2 and 3 was warm. At the beginning of the test the lambs in the 4 lots averaged respectively 75.5, 85.25, 83.75, and 84.25 lbs., the total gains in flesh during the 99 days of the trial being respectively 114, 91, 124, and 110 lbs., and the gains in fleece 28, 35, 32, and 34 lbs. The average cost of a pound of gain was 4.81, 5.24, 3.60, and 3.74 cts., the alfalfa hay eaten per lb. of gain 5.18, 4.84, 5.17, and 4.60 lbs., the grain 3.77, 4.27, 3.21, and 3.53 lbs., respectively. So far as could be observed warming the water had no marked effect on the quantity consumed, the amounts drunk by the 4 lots per lb. of gain averaging 14.64, 16.12, 14.17, and 13.82 lbs., respectively. The dressed weight was very nearly the same in lots 1, 3, and 4, averaging 63.4, 63.2, and 64.7 per cent of the live weight. In lot 2 it was somewhat less, averaging 61.2 per cent. The profits obtained with the lots fed mixed grains (lots 1 and 2) were \$2.81 and \$2.30, being much smaller than those obtained in the case of the lots fed corn (lots 3 and 4), which were \$4.91 and \$4.60. The authors calculate that 1 lb. of corn had a feeding value equal to 1.19 lbs. of the mixed grains used in this test. Regarding the other points studied the following conclusions are drawn:

"Shropshire grade lambs made much better gains than common western lambs when fed the same ration. Nine Shropshire grades made average gains of 43.6 lbs., and 7 native western lambs made an average of 31 lbs.

"Our trials with warm and cold water given to fattening lambs did not show any advantage of one over the other."

Feeding beet pulp to lambs, H. H. GRIFFIN (*Colorado Sta. Bul.* 76, pp. 10).—Using 2 lots of 125 lambs each, the value of beet pulp as a feeding stuff was tested. In the beginning of the test the lambs in lot 1 averaged 61 lbs. per head and those in lot 2 averaged 62 lbs. Both lots were fed the same quantity of alfalfa hay daily. In addition lot 1 was given corn, the amount finally fed being 9 oz. per head daily, and lot 2 beet pulp, the largest amount which could be satisfactorily fed being 6.5 lbs. per head daily. After 60 days the amount of beet pulp was diminished, as the supply was running low, and 6 and later 10 oz. of corn per head daily was added to the ration until the close of the test. During the 114 days covered by the trial the average gain per lamb in the 2 lots was 86.7 and 85 lbs., respectively. The total amount of alfalfa hay consumed by lot 1 was 23,165 lbs. and corn 11,245.5 lbs. The total amounts of alfalfa hay, beet pulp, and corn consumed by lot 2 were 59,444, 23,630, and 2,595.5 lbs., respectively. The amount of water consumed by the corn-fed lot was much greater than that consumed by the beet-pulp lot, the total amount in the 2 cases being 48,313 and 15,705 lbs. At the close of the test 2 lambs from

^a Estimated on the basis of 5 lambs.

each lot were sold to local butchers. The proportion of dressed meat was found to be about the same in both cases, according to the author, while the flesh of the corn-fed lot was regarded as superior in respect to color and the proportion of fat on the outside of the carcass. No other differences were observed in the character of the meat, it all being of good quality. The remainder of the lambs were sold in Kansas City, those fed corn bringing \$3.71 per head and those fed beet pulp \$3.64. The average loss in weight per head of the 2 lots during shipment was 9.4 and 9.2 lbs.

In discussing the feeding value of pulp the author calculates that a ton is equivalent to 200 lbs. of corn.

"Owing to the bulky nature of the pulp not enough of it can be consumed by lambs to produce sufficient fat to finish them; hence it should be fed to the greatest extent at the commencement of feeding. What is fed in the latter part of the feeding period should be used as an appetizer and a regulator of the bowels rather than for the fat it produces. Pulp fed in large quantities produces a soft flesh.

"The matter of transportation is a very essential one for the farmer to consider in the utilization of pulp. For the profitable use the yards must be near the factory or to railway facilities. When large quantities of pulp are fed to animals confined in small lots the lots become very foul, much to the discomfort of the animals and loss to the feeder."

Lamb feeding in Colorado, L. CLARKE (*U. S. Dept. Agr.; Bureau of Animal Industry Rpt. 1901*, pp. 275-278, pls. 2).—Statistics are given regarding lamb raising in Colorado, an enterprise which the author believes may be greatly extended with profit, judging by the favorable results which have been obtained in the past.

Progress of the Angora goat industry in 1901, G. F. THOMPSON (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901*, pp. 457-479, pls. 19, fig. 1).—The author summarizes information received from a variety of sources regarding the number of goats kept, care of goats, their value for clearing land of brush, and related topics.

The Angora goat industry of Asia Minor, W. C. BAILEY (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901*, pp. 493-506, pls. 3).—A number of goat raisers in Asia Minor were visited by the author, who describes their flocks, methods of caring for the goats, etc. Four animals, which seemed especially desirable, were procured for importation into the United States.

The economic feeding of plantation stock under the present conditions of high-priced grain, W. C. STUBBS (*Louisiana Planter*, 28 (1902), No. 11, pp. 178-181).—The feeding of farm animals is discussed with especial reference to local conditions. The successful use of molasses for farm animals, including horses and mules, is noted. According to the author, mules will eat with relish 8 to 12 lbs. of molasses per head daily, and this material is extensively fed to mules in Louisiana. The value of cotton-seed meal for horses and mules is also discussed. At the Louisiana stations 1 to 2 lbs. per mule per day have been fed with success. This should be gradually added to the ration, carefully mixed with other feeds, until the mules learn to relish it, and care should be taken that no uneaten residues ferment in the feed boxes. Six lbs. is regarded as the maximum quantity which can be safely fed, and this amount should be led up to gradually. Only bright yellow cotton-seed meal of a nutty, pleasant odor and taste should be used as a feeding stuff, according to the author, and all reddish and musty meal should be avoided.

Preparation of molasses feeds on the farm, A. GRÉGOIRE (*L'Ing. Agr. Gembloux*, 12 (1902), No. 11, pp. 538-543, figs. 3).—Domestic methods of preparing molasses feeding mixtures are described.

Molasses as food (*Amer. Vet. Rev.*, 26 (1902), No. 4, pp. 283-285).—Brief notes on the successful use of molasses feeds for horses in France.

Maintenance and restoration of muscular energy by sugar, L. GRANDEAU (*Jour. Agr. Prat.*, n. ser., 4 (1902), No. 33, pp. 206-209).—The value of sugar as a

source of muscular energy is discussed on the basis of experiments reported several years ago by V. Harley and U. Mosso.

Molasses for feeding animals; its use in feeding draft animals, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 4* (1902), No. 44, pp. 567-569).—The favorable results which have been obtained in feeding molasses to cattle used as beasts of burden and to horses were discussed. The author believes that molasses is a useful feeding stuff for draft animals.

Feeding molasses at domaine d'Arcy-en-Brie. Ration for horses and cattle, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 4* (1902), No. 45, pp. 599, 600).—An instance of the successful use of molasses in feeding horses and cattle is cited. The molasses ration for horses cost on an average 28 cts. The ration which is satisfactorily replaced cost 44 cts. In the case of cattle similar values were 26 cts. and 33 cts.

Molasses feeds and the feeding of horses, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 4* (1902), No. 48, pp. 697, 698).—The author discusses molasses feeds and notes the successful use of such a material, called "pain mélasse," in the feeding of horses belonging to one of the large Paris cab companies.

Molasses feeds and horse feeding. Experiments with peat molasses, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 4* (1902), No. 50, pp. 760-764).—Peat molasses is described and a test briefly reported in which this material was fed to horses with satisfactory results. Maize and chopped oat straw was also fed in addition to peat molasses, the amount of molasses consumed per day being over 1.5 kg. The daily work performed was equal to 387,000 kgm. The body weight was nearly maintained during the 11 months of the trial. The experience of some other investigators with this feeding stuff is quoted and discussed.

Molasses feeds in relation to horse feeding. Experiments with molasses-straw, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 4* (1902), No. 51, pp. 793-795).—An experiment is briefly reported in which a horse weighing 425 kg. was successfully fed a ration consisting of 4.133 kg. of molasses-straw and 3.117 kg. of maize, with a little salt, for some 4 months. Molasses-straw is prepared by drying a mixture consisting of 40 to 43 per cent chopped straw and 57 to 60 per cent molasses at 110°.

Practical guide for horse buyers, J. PERTUS (*Guide pratique de l'acheteur de chevaux. Paris: B. Baillière & Sons, 1902, pp. 148, figs. 78*).—The various points of a horse which are regarded as of use to horse buyers are discussed, as well as French legislation on the subject and related topics.

The horse and different breeds of horses, F. A. and E. S. ZERN (*Das Pferd und seine Rassen. Leipzig: Hermann Seemann, 1902, pp. 229, pls. 17, figs. 67*).—In this volume, which is designed as a text-book, the authors discuss horse breeding and the principal breeds of horses found in the Orient and in western countries.

The question of temperament in raising army horses in the Prussian Provinces, O. GAGZOW (*Inaug. Diss., Univ. Jena, 1902, pp. 90*).—The comparative merits of horses of lively and phlegmatic temperament are considered with special reference to the raising of army horses. The present condition of the horse industry in Germany is also taken up, much statistical and other information being given.

American breeds of fowls, T. F. MCGREW (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901, pp. 513-565, pls. 16, figs. 13*).—This description of the Plymouth Rock and Wyandotte breeds of fowls has been noted from other publications (E. S. R., 13, pp. 484, 777). The article is prefaced by a brief discussion of these breeds by D. E. Salmon.

Preservation of eggs (*Jour. Soc. Cent. Agr. Belg. 49* (1902), No. 11-12, p. 401).—A brief note on E. Teisler's method of preserving eggs with fluo-silicic acid and its salts, marketed as an egg preservative under the name of Ovioval.

Turkey culture (*New York: Excelsior Wire & Poultry Supply Co., 1901, pp. 90, figs. 15*).—In this publication a number of articles by different authors on breeds of turkeys, turkey management, marketing, diseases, and related topics are included.

The national standard squab book, E. C. RICE (*Boston, 1902, pp. 80, pl. 1, figs. 19*).—This book, which is based on the author's experience in squab raising, contains chapters on the feeding and care, killing and marketing squabs, pigeon diseases, and similar topics.

Profit in quail breeding (*Chicago: Pet Stock News, 1902, pp. 32*).—Directions are given for raising quail as pet stock or for market. The subjects discussed are taming wild quail, hatching, feeding and care, and related topics.

DAIRY FARMING—DAIRYING.

The dairy industry and dairy markets in Porto Rico, with notes on St. Thomas and Cuba, R. A. PEARSON (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901, pp. 306-397, pls. 35, figs. 6*).—This report upon the production and sale of dairy products in the islands of Porto Rico, St. Thomas, and Cuba, is based upon observations made by the author during 2 months spent in Porto Rico, and a shorter time in the other islands. The article is profusely illustrated and contains considerable statistical matter as regards the number of cattle in the islands and the imports of butter, cheese, and condensed milk.

The natural conditions of Porto Rico are considered as apparently favorable to dairying. Good dairy cows and improved methods are needed for the development of the industry. Among the topics considered in connection with dairying in Porto Rico are the value of land, water supply, cattle foods, origin and characteristics of native cattle, methods followed on dairy farms, and the milk, butter, and cheese produced. Analyses show that the native cows produce a good quality of milk. The yield, however, is small. Practically all the butter is imported. During the year 1900 this amounted to 307,469 lbs. The largest part of the butter, including the oleomargarine entered as butter, is from the United States, and is stated as occupying a low position in the markets of Porto Rico. The best quality of butter is that obtained from Denmark, the imports of which during 1900 amounted to 32,573 lbs. During 1900 the butter exported from the United States to Porto Rico was 26,825 lbs. and the oleomargarine 219,140 lbs. Analyses by G. E. Patrick of 92 samples of butter purchased in the three islands, but mostly in Porto Rico, are included, as are also analyses of 5 samples of cheese sold in Porto Rico. In discussing pasteurization as applicable to the handling of market milk in Porto Rico the author notes briefly experiments conducted at his request by C. F. Doane at the Maryland Station and H. Hayward at the Pennsylvania Station.

An account is given of experimental shipments of butter forwarded by this Department to Porto Rico for the purpose of ascertaining the character of the transportation facilities and the condition of the butter upon reaching its destination, and also to aid in forming an opinion as to the opportunity for developing a trade in dairy products. The butter shipped was made at creameries in Vermont, New York, Wisconsin, and Iowa, and was of the best quality. Details are given concerning the manufacture, composition, shipment, and sale of the butter. In summarizing the results many suggestions are made for the benefit of persons intending to make shipments in the future. "During most of the year, if not all, our best butter can be safely forwarded with present facilities of transportation, though these should be much improved. . . . Porto Rico offers only a limited market for butter, of which but a small portion may be of best grades. A very few creameries could easily supply the market for good butter. But the demand for both the better and the cheaper grades will certainly increase when they become well known and are offered at reasonable prices."

The amount of cheese imported into Porto Rico during 1900 was 710,956 lbs. Several cheeses were shipped experimentally by the Department.

The dairy conditions in St. Thomas and Cuba are more briefly described.

Investigations of methods of milking, F. W. WOLL (*Wisconsin Sta. Bul.* 96, pp. 9, figs. 18).—Considerable importance is attached by the author to the method of milking originated by Hegelund, previously noted (*E. S. R.*, 14, p. 286). In the introduction to the bulletin the method is described and the manipulations are illustrated. The physiology of milk secretion is also considered. Extensive tests of the method made with a number of dairy herds are reported in detail and discussed. The author's summary of the results is quoted below in full:

"(1) The milking experiments conducted by the writer were made partly with cows in our university herd, partly with cows in 12 different Wisconsin dairy herds. The aim in all cases was to ascertain the gain in the production of milk and butter fat obtained by a system of manipulations of the udder after the regular milking was finished (Hegelund method); where the regular milker did not milk clean, the gain obtained by clean milking, together with manipulation of the udder, was ascertained. The plan of the experiments was therefore such as to show the character of the work done by the different milkers.

"(2) In our university herd the average daily production of milk from 24 cows was increased by 4.5 per cent by means of the manipulation method and the production of fat was increased by 9.2 per cent (range 3 to 30.2 per cent for individual cows), as the result of a milking experiment continued for 4 weeks; the average gain in milk being 1 lb. and in fat 0.09 lb. per head per day.

"(3) A similar average increase in production was obtained for the 12 dairy herds tested, viz, a gain of 1.08 lbs. in the daily production of milk per cow and 0.1 lb. of fat. The results obtained in this investigation, extending over a period of 4 months, with cows in all stages of lactation, indicate that this gain is maintained through the whole period of lactation. An increase in the daily production of butter fat per cow of one-tenth of a pound, for the million cows in the State would mean an annual gain of 30,000,000 lbs. of butter fat if the cows give milk 300 days in the year; the value of this increase to the dairy industry of the State would be about \$6,000,000, on basis of a valuation of 20 cts. a pound for butter fat, a figure considerably below average Elgin prices.

"(4) The largest amount of milk obtained from a cow by the manipulation method, after the regular milking was done, was 5.5 lbs. per day and the lowest, 0.20 lb. The corresponding figures for fat production was 0.64 and 0.02 lb. The former figure is considerably above the average total daily production of cows in this or other States.

"(5) The greater portions of the gains obtained came through lack of care on part of the regular milker as the cows were not milked perfectly clean. But even in herds where the milkers did their work well, there were always one or more cows which gave an increase of nearly a pound of milk and one-tenth of a pound of butter fat by the manipulation method.

"(6) The milk obtained by the manipulation method is similar in composition to that of "strippings;" on the average for all herds it contained 10.32 per cent fat and was found to be about $2\frac{1}{2}$ times richer than the ordinary milk. The highest per cent of fat found in the after-milking from any one cow was 23 per cent and from any herd, 14.41 per cent.

"(7) The difference in the work done by different milkers is brought out strongly by the results of the work done. In several cases one milker did his work so much better than the others in the same herd as to be worth nearly \$10 a month more to the owner, on account of the larger yields of milk and fat which he obtained from the cows milked by him.

"(8) The results obtained in this investigation suggest that a thorough system of milking is a foundation requirement in successful dairying. For, aside from directly increasing the production of milk and fat from the cows, exhaustive milking will be likely to maintain a maximum flow of milk throughout the lactation period and to permanently develop the dairy qualities of both the dam and her offspring."

Report on the use of molasses in the feeding of animals, L. NICOLAS (*Compt. Rend. Cong. Soc. Aliment. Rat. Bét.*, 6 (1902), pp. 16-25).—In experiments with 10 cows lasting 2 months the substitution of molasses for concentrated feeds was unfavorable as regards the yield and quality of the milk produced. In further experiments the addition of phosphoric acid to the molasses feed appeared to exercise a very marked influence in increasing the production of milk and butter.

A milk unusually rich in solids, M. H. PRINGREE (*Pennsylvania Sta. Rpt.* 1901, pp. 192-194).—The milk of a healthy, four-year-old, high-grade Guernsey cow during the fourth and fifth months of her second lactation period showed an average fat content of 5.8 per cent. A sample of the milk taken a few days later showed the following composition: Moisture 82.99, total solids 17.01, fat 6.40, casein and albumin 4.37, lactose 5.25, ash 0.99 per cent, specific gravity at 60° F. 1.0372. One month later the composition was as follows: Moisture 84.28, total solids 15.72, fat 5.90, casein and albumin 3.80, lactose 5.34, ash 0.72 per cent, specific gravity at 60° F. 1.035. The daily yield when the 2 samples were taken was, respectively, 12 and 14.3 lbs. The relative proportion of the different constituents indicated that the milk was normal.

Composition of milk in the north of England, S. H. COLLINS (*Jour. Soc. Chem. Ind.*, 21 (1902), No. 24, pp. 1512, 1513).—Average analyses of the milk of 18 cows in October showed a fat content of 3.55 per cent for morning's milk and 4.99 for evening's milk. The corresponding figures for solids-not-fat were 8.67 and 8.38 per cent.

Milk at Copenhagen, H. DE ROTHSCHILD (*Le lait à Copenhague. Paris: O. Doin*, 1903, pp. 36, pls. 12).—A descriptive account of the two principal dairies in Copenhagen, one supplying the city with fresh milk preserved by means of ice and the other with pasteurized milk.

A new bacterium of soapy milk (*Bacterium sapolacticum*), W. EICHHOLZ (*Centbl. Bakt. u. Par.*, 2. Abt., 9 (1902), No. 17-18, pp. 631-633).—The morphological and cultural characteristics of a micro-organism isolated from a sample of milk having a decided soapy taste are reported. The organism, to which the name *Bacterium sapolacticum* is given, produced the same disagreeable taste when inoculated into sterile milk.

A study of some California butters made for export, M. E. JAFFA (*California Sta. Rpt.* 1899-1901, pt. 2, pp. 231-234).—The quality of the butter produced by a dairy herd fed a ration consisting of 60 lbs. of beet pulp silage, 10 lbs. of mixed hay, and 5 lbs. of mixed feed was investigated. Detailed data are given in tabular form as regards the composition and digestibility of the feeding stuffs, the manufacture of the butter, and the composition of the butter made each day for 6 days during August. Analyses were also made of the butter fat. The average composition of the butter was as follows: Water 10.60, fat 86.32, curd etc., 1.27, salt 1.64, and other mineral matter 0.17 per cent. The butter fat contained 6.39 per cent of butyric; 55.68 per cent of palmitin, stearin, etc.; and 37.93 per cent of olein, and had a melting point of 32.7° C. and a refractive index at 25° C. of 1.4598. These figures are compared with analyses made elsewhere, and the tentative conclusion is drawn that beet-pulp silage fed in large quantities to cows has a tendency to produce soft butter.

Investigations on the composition and properties of butter fat from the milk of individual cows, P. BEHREND and H. WOLFS (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 5 (1902), No. 15, pp. 689-719).—Determinations are given of the melting point and the refractometer, Reichert-Meissl, Hübl, Köttstorfer, and Hehner numbers of the butter fat obtained separately from the milk of 10 cows, and the relation of the different values is discussed. An increase in the melting point was associated with a decrease in the Reichert-Meissl number and an increase in the Hehner number. As the refractometer number increased the Reichert-Meissl and Köttsstorfer numbers decreased and the Hübl and Hehner numbers increased. An increase

in the Reichert-Meissl number was accompanied by a decrease in the Hübl and Hühner numbers and an increase in the Köttstorfer number.

The nonsaponifiable substance in butter fat, A. KIRSTEN (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 5 (1903), No. 18, pp. 833-856).—This consists for the most part of cholesterol. Phytosterol, lecithin, and a yellow coloring matter are present to a small extent. Numerous determinations of crude cholesterol were made by the Böhmer method, which is described. In the butter fat from cows 10 to 13 years old, in different stages of lactation, the content of cholesterol averaged 0.46 per cent. In the fat from cows 6 to 7 years old the content was 0.38 per cent and in the fat from cows 4 years old the content was 0.42 per cent. Cows during the first lactation period showed an average content of 0.39 per cent of cholesterol. At the beginning, middle, and end of lactation the percentages of cholesterol were, respectively, 0.375, 0.44, and 0.50. The stage of lactation had apparently some slight influence upon the cholesterol content.

Constituents of Emmenthaler cheese, E. WINTERSTEIN and J. THÖNY (*Ztschr. Physiol. Chem.*, 36 (1902), No. 1, pp. 28-38).—In studying the decomposition products formed in Emmenthaler cheese during the process of ripening the authors identified histidin, lysin, pentamethylenediamin, and tetramethylenediamin, and probably guanidin. Tyrosin was found in very old cheese.

VETERINARY SCIENCE AND PRACTICE.

The bactericidal action of blood serum and blood plasma, A. PETTERSSON (*Arch. Hyg.*, 43 (1902), No. 1, pp. 49-83).—An extensive series of experiments was conducted by the author for the purpose of determining the power of blood serum and blood plasma of different experimental animals in destroying bacteria. The serum and plasma used in these experiments came from cattle, rabbits, guinea pigs, dogs, sheep, and cats. Detailed notes are given on the processes employed in obtaining the serum and plasma, and on the behavior of these substances as obtained from different animals. During the author's experiments it was found that the plasma of the circulating blood contains substances which destroy bacteria (alexin). After the blood is removed from the body its bactericide action may be either increased or diminished. The quantity of alexin may be increased by alexin which is derived from the leucocytes. The amount of alexin in the serum may be diminished by absorption into the fibrin. The action of the alexin may be weakened by the appearance of the better nutritive condition of the animal, since under such circumstances nutritive substances may be derived from the blood corpuscles. In some species of animals the alexin obtained from leucocytes outside of the animal body is so small in quantity that the bactericide action of the serum is slighter than that of the plasma. In other species of animals, on the other hand, so large a quantity of alexin is derived from the leucocytes after the blood is removed from the body that the bactericide action of the serum is considerably increased.

The antibodies of the blood serum in animals treated with blastomycetes, F. SANFELICE (*Centbl. Bakt. u. Par.*, 1. Abt., 32 (1902), No. 5, Orig., pp. 360-365).—The experiments reported in this paper were made on 4 dogs which had been immunized against *Saccharomyces neoformans* and a pathogenic blastomycete isolated by Plimmer. The results of the author's observations may be stated as follows: In the blood serum of animals which have been immunized against the pathogenic blastomycetes by repeated injections of the same species of blastomycete attenuated by exposure to heat, antibodies or sensibilizing substances were found. These bodies are not to be found in the blood serum of animals infected with blastomycetes.

The mutual reaction between successive processes of immunization in the animal organism, L. VERNEY (*Centbl. Bakt. u. Par.*, 1. Abt., 32 (1902), Nos. 4, Orig., pp. 290-307; 5, pp. 366-376).—During the author's extensive experiments with

guinea pigs and rabbits it was found that an animal could be immunized against one pathogenic organism and could then be immunized against another organism without losing its immunity toward the first species. It was found that a partial immunity produced by one inoculation could be considerably increased by subsequent inoculations. In one experimental animal a marked agglutinating power was gradually developed against 3 micro-organisms, the typhoid bacillus, *Bacterium coli commune*, and the pyocyaneus organism.

Immunization experiments with Kraus' bacillus of rabbit influenza, E. JACOBITZ (*Centbl. Bakt. u. Par., 1. Abt., 32 (1902), No. 4, Orig., pp. 288, 289*).—An outbreak of influenza occurred among the rabbits in the laboratory in which the author was working. Attempts were made to check the disease by different methods of immunization. Rabbits were first treated with killed cultures, the experimental animals receiving gradually larger doses of this material. The effect of the treatment was nil, and no trace of immunity was to be observed. An attempt was also made to protect rabbits against disease by increasing doses of living bacilli in very dilute solutions. The results of these experiments were also negative. All attempts on the part of the author to produce artificial immunization indicate that this result is impossible.

The effect of glycerin on virus, V. GALTIER (*Jour. Méd. Vét. et Zootech., 5. ser., 6 (1902), Feb., pp. 65-71*).—Since glycerin is used so extensively in the preservation of virus of different sorts, the author undertook experiments to determine the length of time during which virus could be preserved in this reagent without losing its virulence. The experiments included tests with anthrax, glanders, and tubercle bacilli. It was found that fresh anthrax virus prepared from the pulp of affected organs rapidly lost its virulence when preserved in pure glycerin. At the end of 55 hours such material was attenuated to such an extent that it no longer produced infection in guinea pigs or rabbits, even when inoculated in large doses. When affected kidneys and spleens were preserved entire or in large pieces without trituration in pure glycerin the virulence of the bacillus was attenuated much more slowly. During the experiments it was found that anthrax virus containing spores, as compared with non-spore-bearing anthrax bacilli, resisted the action of glycerin much longer. The virulence of glanderous material was retained in glycerin for a period of 10 to 12 days, or in some instances 17 or 18 days. It is believed, therefore, that glanderous and tuberculous material or tissues suspected of being infected with these diseases may be safely preserved for a few days in glycerin, until opportunity is had for a bacteriological or inoculation test.

Aseptic metallic powder, L. HOFFMANN (*Berlin. Thierärztl. Wehnschr., 1902, Nos. 1, pp. 1-4; 7, pp. 109, 110*).—The author conducted a number of experiments with 2 kinds of powder obtained from the establishment of a metal beater. It was learned by inquiry that these finely granulated powders, one of which was silver and the other golden in color, exercised no injurious effects upon the skin of man or animal. Experiments were therefore instituted for the purpose of testing the value of these powders in the treatment of wounds. During these experiments quite satisfactory results were obtained. It was found that the wounds could be directly covered with either of the powders, and that little subsequent dressing or treatment was required.

The action of aseptic metallic powders, SCHMIDT (*Berlin. Thierärztl. Wehnschr., 1902, No. 3, p. 39*).—The author takes issue with Hoffmann concerning the action of metallic powder on wounds. Hoffmann believed that the powders exercised merely a mechanical effect upon the wounds, preventing an infection from the outside, while the present author maintains that the aseptic action of metallic powders must be ascribed partly to their chemical properties as well as to their physical properties.

The therapeutic application of formaldehyde in a fixed form, F. GLAGE (*Deut. Thierärztl. Wehnschr., 10 (1902), No. 14, pp. 133, 134*).—The author found that

the colostral milk of cows when treated with formaldehyde formed a uniform firm mass. This reaction was made use of in producing an antiseptic salve in a convenient and cheap form. The author found that by adding formaldehyde to colostral milk, a firm and effective antiseptic salve could be produced and good results were obtained from its use in the treatment of wounds.

Tuberculosis of animals in some of its relations to human tuberculosis, D. E. SALMON (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901, pp. 257-266*).—Notes are given on the prevalence of tuberculosis in various parts of the United States as shown by statistics obtained from tuberculin tests. These tests have been reported in sufficient numbers to form a fairly reliable basis as to the percentage of tuberculous animals. Special attention is given to a discussion of the presence of this disease in dairy herds and hogs. During recent years tuberculosis has increased in extent in cattle and hogs in this and other countries. The author believes, therefore, that great care should be exercised in keeping the human food supply as free as possible from contamination with the tubercle bacillus. On account of the large number of tuberculous beef animals which are slaughtered and the relatively larger number of tuberculous cows the milk of which is used as food, special precaution in this direction is believed to be highly desirable. Notes are given on a number of cases related in the literature of this subject concerning apparent transmission of tuberculosis from animals to man.

Virulence of the bovine tuberculosis bacillus for monkeys and the effect of tuberculins made from tuberculosis bacilli derived from different animals, E. A. DE SCHWEINITZ and E. C. SCHROEDER (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901, pp. 579-582*).—An African baboon inoculated with 1 cc. of a bovine tubercle culture died of generalized tuberculosis. An American ring-tail monkey was fatally infected from an injection of $\frac{1}{2}$ cc. of the same culture. Comparative tests were made of bovine and human tubercle cultures on baboons and rhesus. In every case the animals died of generalized tuberculosis. The authors report a number of observations which indicate that tuberculous animals respond to tuberculin test without regard to the source of the cultures from which the tuberculin is made. The experiments as a whole are believed to indicate the great virulence of bovine tubercle bacilli for man.

Composition of tubercle bacilli derived from various animals, E. A. DE SCHWEINITZ and M. DORSET (*Centbl. Bakt. u. Par., 1. Abt., 32 (1902), No. 3, Orig., pp. 186-192*).—A report is made on the investigations of the authors with regard to the composition of tubercle bacilli. The material upon which these investigations were made consisted of attenuated bacilli of human origin, virulent bacilli of human origin, virulent bacilli from cattle, hogs, horses, and birds. During the authors' investigations it was found that the highest percentage of ether extract was obtained from the attenuated bacilli of human origin, the other bacilli being arranged in this regard in the following order: Bacilli from the horse, virulent human bacilli, and bacilli from cattle, birds, and hogs. The results obtained indicate clearly that there is a difference in the composition of tubercle bacilli from different sources, perhaps equally as great as the difference in morphology. It appears also that there is a relationship between tubercle bacilli from different sources and that the degree of virulence may be connected with quite remarkable differences in composition.

Note on branched forms of tubercle bacilli found in cultures, M. DORSET (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901, pp. 572, 573, fig. 1*).—A brief account is given of a number of branched forms of tubercle bacilli, and these are arranged in the order which is believed to represent the sequence in the process of branching. A species of streptothrix was found in the same culture and the attempt has been made to determine what influence the presence of this organism had upon the branching of the tubercle bacillus.

Agglutination of the tubercle bacilli and treatment of tuberculosis with the new tuberculin of Koch (bacterial emulsion), F. THELLUNG (*Centbl. Bakt.*

u. Par., 1. Abt., 32 (1902), No. 1, Orig., pp. 28-48).—The literature relating to the value of the agglutination test in the diagnosis of tuberculosis is critically reviewed. The author's experiments were made on healthy and infected guinea pigs and rabbits. Extensive series of experiments were conducted in 2 ways. In one series, the animals were infected with virulent tubercle bacilli and then treated with new tuberculin; while in the second series the experimental animals were first treated with new tuberculin, and subsequently infected with virulent tubercle bacilli. Further experiments were made on healthy guinea pigs, during which the animals were inoculated with ground or emulsified bacteria for the purpose of testing the effect of these preparations on healthy animals. The results of these experiments are presented in detail, but the essential points may be stated as follows: The agglutination of tubercle bacilli does not occur regularly in cases of tuberculosis. This reaction, therefore, can not be considered at the present time as a practical means of diagnosis. The tubercle bacilli may be agglutinated as a result of subcutaneous injection of Koch's bacterial emulsion in doses of a few milligrams. No favorable action of the new tuberculin of Koch upon the course of experimental tuberculosis could be observed. It was found that pulverized tubercle bacilli as well as the new tuberculin of Koch, or bacterial emulsion, might contain active virulent tubercle bacilli.

Causes and suggestions for the prevention of tuberculosis, H. D. HOLTON (*Sanitarian, 49 (1902), No. 394, pp. 193-203*).—A general discussion of the means of transmission of tuberculosis among human beings. It is argued that the danger from the meat and milk of tuberculous animals may have been somewhat exaggerated, but, in the author's opinion, such danger does exist to a considerable degree, and it is believed, therefore, that the safeguards which have thus far been adopted in preventing transmission of tuberculosis by meat and milk should not be abandoned.

Tuberculosis of the udder, A. MOSER (*Arch. Wiss. u. Prakt. Tierh., 28 (1902), No. 1-2, pp. 1-27, figs. 11*).—A review of the literature concerning the histology of mammary tuberculosis is presented, in connection with a bibliography of 33 titles. The author found that in mammary tuberculosis in cows the formation of new tissue begun in all cases with the proliferation of the secretory epithelium. This tissue was subsequently replaced by cells which arose from wandering cells. While the greater part of the tuberculous neomorph was found to consist of hardened lobules of the glands, the cooperation of the interacinous connective tissue was of less importance. The newly formed tissue undergoes necrosis, caseation, and calcification, in the order named.

Tuberculosis in the nerve centers in dogs, G. PETIT (*Rec. Méd. Vét., Paris, 8. ser., 9 (1902), No. 6, pp. 165, 166*).—Brief notes are given on the occurrence of tubercular meningitis, and other forms of tuberculosis in the central nervous system of dogs.

Foot-and-mouth disease, E. THIERRY (*Jour. Agr. Prat., n. ser., 3 (1902), No. 23, pp. 735-739, pl. 1*).—A general description is given of the symptoms of the disease, post-mortem findings, and of the treatments usually applied in combating this plague.

Foot-and-mouth disease of cattle and its treatment according to the method of Baccelli, H. MIESSNER (*Deut. Med. Wchnschr., 28 (1902), No. 10, pp. 176, 177*).—The author gives a brief review of the literature thus far published on the subject of intravenous inoculation of corrosive sublimate in the treatment of foot-and-mouth disease. The experiments of the majority of investigators, as well as those of the author, indicate that little success is to be hoped for from the use of this method.

A study of the central nervous system in cases of the foot-and-mouth disease of cattle, G. SCAGLIOSI (*Deut. Med. Wchnschr., 28 (1902), No. 12, pp. 197-199*).—Pieces of the brain and spinal cord from cattle affected with foot-and-mouth disease were carefully fixed and preserved for microscopic study. It was found that the nerve cells underwent profound alterations as a result of infection by the disease, and these changes in the central nervous system may be utilized in diagnosing the disease

and in determining whether affected animals have recovered to such an extent as to render the meat safe for human consumption. The more important changes in the nervous system were found in the ganglion cells. Nissl's corpuscles became disintegrated, and the whole nerve cell exhibited a tendency to become homogeneous and later to form vacuoles in their substance. The changes in the ganglion cells of the brain and spinal cord were essentially the same.

Anthrax and blackleg, L. C. TIFFANY (*Illinois State Bd. Live Stock Com. Bul. No. 3* (ser. 1901-2), pp. 8).—A brief popular discussion of the symptoms, cause, transmission, and prevention of anthrax and blackleg.

Anomalous forms of anthrax bacillus isolated from the blood of a bull dead of this disease, J. LIGNIÈRES and H. DURRIEU (*Rec. Méd. Vét., Paris, 8. ser., 9* (1902), No. 4, pp. 102-107, figs. 4).—Cultures of anthrax bacillus taken from the blood of a bull which had died of natural infection with anthrax were made on various nutrient media, including peptone bouillon, gelatin, gelose, and milk. Great variation in the form of the organisms thus obtained was observed. Inoculation experiments on guinea pigs, rabbits, and sheep demonstrated that all these different forms of the anthrax bacillus were equally virulent.

Toxic paralysis of a carbunculous (anthrax) nature, A. SCLAVO (*Centbl. Bakt. u. Par., 1. Abt., 32* (1902), No. 3, Orig., pp. 201-207).—In conducting experiments with antianthrax vaccine the author observed that paralysis quite frequently occurred in the animals which were being used for experimental purposes. Detailed notes are given on a number of such cases. The symptoms of paralysis appeared from 16 to 31 days after injection of the serum and pure culture. These symptoms were remarkably uniform. A second injection of anthrax bacilli and serum in a rabbit which already showed symptoms of paralysis did not cause an anthrax infection, but the animal died like the other cases of paralysis. It is believed that the poisonous substance, which exercised its effect directly upon the posterior portion of the spinal cord, is analogous to the toxons observed in diphtheria. It is suggested that as a result of the excessive injections of anthrax cultures and serum the blood acquired increased resisting power toward the anthrax bacilli, but lost, at the same time, its normal bactericide properties for destroying toxic substances which caused paralysis.

The existence of chronic pleuro-pneumonia in the interior districts of France, H. MARTEL (*Rec. Méd. Vét., Paris, 8. ser., 9* (1902), No. 8, pp. 174-179).—The author presents a general summary of the results of his observations and experiments in determining the extent and prevalence of pleuro-pneumonia in a chronic form in France. From these experiments and observations it is concluded that infected animals may remain contagious for several years. It was shown that the virulence of the virus is preserved without change in infected animals in different foci, and that new foci may form successively in infected animals. In order to avoid outbreaks of pleuro-pneumonia in a virulent form it is urged that veterinarians at abattoirs give special attention to the destruction of any foci of pleuro-pneumonia which may be found in the lungs of cattle.

Pleuro-pneumonia in the mammary gland, E. NOCARD (*Rec. Méd. Vét., Paris, 8. ser., 9* (1902), No. 4, pp. 88-92, figs. 3).—Since it is a well-known fact that the mammary gland of cows, especially when it is active, is very susceptible to inoculation with such diseases as tuberculosis, anthrax, and aphthous fever, the author determined to undertake experiments in inoculating the udder with the virus of pleuro-pneumonia. The experiments are described in detail. The inoculation is made without causing any lesion of the udder. The following results were obtained from these experiments: When the organism of pleuro-pneumonia was introduced into the milk sinus without injury to the mammary gland, pathological lesions were produced similar to those which accompany subcutaneous or intramuscular inoculations. A pure culture of the organism was maintained in the milk. The organism

was found in large quantities in the milk of the inoculated udder, for a long time after recovery from the effects of inoculation. The virulence of the organism, recovered from the mammary gland, was tested, and was found to be greater than before inoculation.

Pasteurellosis of cattle in Indo-China, J. BLIN and J. CAROUGEAT (*Rec. Méd. Vét., Paris, 8. ser., 9 (1902), No. 4, pp. 107-118, fig. 1*).—This disease, which, according to the author, is frequently mistaken for rinderpest in Indo-China, is described in detail and notes are given on its symptoms, lesions, etiology, virulence, and pathogenicity. In buffaloes the disease is observed only in the acute form. The onset is sudden, and the chief symptoms are an acceleration of the respiration, elevation of temperature, and congestion of the mucous membranes. The lesions produced in the acute form are of a congestive and hemorrhagic nature, but it is a remarkable fact that the musculature remains intact. In the chronic form the most serious lesions occur in the lungs and intestines. As a result of the author's studies and experiments, it is concluded that the disease known in Indo-China as rinderpest is a hemorrhagic septicemia belonging to the group of pasteurelloses. It is believed that the practice of slaughtering diseased animals is useless. Sanitary measures are more efficacious in restricting the number of infected centers. It is recommended that the sale of diseased animals for meat be prohibited, except where the animals are to be taken immediately to a slaughterhouse. Injections of artificial serum or defibrinated blood are of considerable value in bringing about a recovery of cattle affected with a chronic form of the disease.

Prevention of white scour in calves (*Jour. Dept. Agr. and Tech. Instr. Ireland, 2 (1902), No. 3, pp. 504-510*).—The nature of this disease as determined by Professor Nocard is described in detail. The methods recommended for controlling the disease included the antiseptic treatment of the external genital organs of the cow, and a similar treatment of the navel cord of the calf immediately after birth. The solution for treating the navel cord may contain 70 gr. iodid potash in 2 pts. water, and this treatment may be followed with another solution containing 35 gr. of iodine in 2 pts. of methyl alcohol.

Hints for spaying cattle, D. WILSON (*Jour. Dept. Agr. Victoria, 1 (1902), No. 3, pp. 249, 250*).—The author summarizes, in brief recommendations and directions, the results of his personal observations on this subject. It is recommended that in heifers which are intended for fattening the operation should be performed at about 12 months of age.

Danger from ergot and wild rye, A. T. PETERS (*Agriculture [Nebraska], 1 (1902), No. 7, pp. 25, 26*).—Numerous complaints have been received from various parts of the State reporting ergotism in various forms in cattle and other domesticated animals. Brief notes are given on the usual symptoms produced by eating too much ergot in wild rye and from other sources. Attention is called to the desirability of close observation on the part of stockmen for the purpose of detecting the presence of ergot spurs in wild grasses.

Laboratory notes on poison in sorghum, S. AVERY (*Jour. Comp. Med. and Vet. Arch., 23 (1902), No. 11, pp. 704-706*).—During chemical studies at the Nebraska Experiment Station prussic acid was found in the living leaf of young and old sorghum plants. Kafir corn was also found to contain this poison. In other plants, however, such as clover, alfalfa, grasses, and corn, no trace of prussic acid was found. Prussic acid is found in sorghum and Kafir corn in the leaves but not in the seed or roots. The amount of the poison in stunted plants appears to be greater than that in vigorous plants.

Equisetum palustre, C. A. WEBER (*Arb. Deut. Landw. Gesell., 1902, No. 72, pp. 63, pls. 3*).—A general review is given of the experience of the author and other investigators with regard to the poisonous character of this plant, which evidence is presented to show that the poisonous effects of the plant are not due to its content

of silica but rather to some organic substance thus far undetermined. The plant appears to be especially dangerous to cattle, and only rarely affects horses. Notes are given on the anatomical characters, distribution, habit of growth, and means of combating this species. With regard to treatment of poisoned animals, it is recommended that all animals that show symptoms of poisoning by this plant should be immediately removed to pastures where the plant does not grow, and that treatment should be applied according to the symptoms which are manifested.

Screw worm in cattle at St. Lucia. H. MAXWELL-LEFROY (*Imp. Dept. Agr. West Indies, Pamphlet No. 14, 1902, pp. 13*).—This bulletin contains an account of the life history, mode of attack, injury, and means of combating screw-worm attacks upon cattle. The insecticides which are recommended for killing screw worms are carbolic acid and sweet oil, carbolic acid alone, Jeyes' fluid, spirits of turpentine, tar, and fish oil. The author recommends that an effort be made to locate the breeding places of the screw flies, and that the flies be destroyed in such localities.

Sour grass and ticks (*Agr. News [Barbados], 1 (1902), No. 7, p. 105, fig. 1*).—Observations are reported on *Andropogon pertusus*. It is claimed that horses and cattle that graze upon this grass are remarkably free from infestation by ticks and other insects, and this is explained by assuming that the sour grass contains a volatile principle which is excreted through the skin and which is offensive to ticks.

Treatment of Strongylidæ in the stomach and intestines of sheep, MOUSSU and MAROTEL (*Rec. Méd. Vét., Paris, 8. ser., 9 (1902), No. 12, pp. 292-298*).—The authors prefer the term gastrointestinal strongylosis for the affection produced by the presence of species of *Strongylus* in the stomach and intestines. In treating cases of this disease the authors obtained best results from feeding 2 to 3 gm. of areca nut mixed with bran to each sheep, according to size. It is recommended that the stables and other quarters be disinfected with quicklime, solutions of sulphuric acid, or sulphate of iron.

Frogs, toads, and carp (*Cyprinus carpio*) as eradicators of fluke disease. C. W. STILES (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901, pp. 220-222, figs. 7*).—Letters from E. N. Hutchinson, of Portland, Oreg., concerning the value of carp in eradicating the fluke disease are reproduced, and mention is also made of a report by W. H. Ashmead to the effect that frogs and toads have been introduced into certain ponds in the Hawaiian Islands for the purpose of destroying snails which serve as intermediate hosts of the flukeworms. It appears from these statements that carp may prove to be of considerable value in this way.

Results of the work against sheep scab in 1901, D. E. SALMON (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901, pp. 583-589*).—Statistics covering the year 1901 show that under the direction of the Bureau of Animal Industry 886,645 sheep were dipped. It was found that 92.4 per cent of the total number of sheep inspected were free from scab. Of the whole number of sheep dipped during 1901, 51.2 per cent were treated with nicotin and sulphur, 34.8 per cent with tobacco and sulphur, and 13.9 per cent with lime and sulphur. A surprising effectiveness was reported from 1 dipping with these preparations. Five stations reported perfect effectiveness for lime and sulphur, 4 stations for tobacco and sulphur, and 3 stations for nicotin and sulphur. From a comparison of these 3 dips for the years 1900 and 1901, it appears that nicotin and sulphur heads the list in effectiveness, followed by tobacco and sulphur, and lime and sulphur. There appears, however, to be very little choice between these 3 dips.

Sheep scab (*Jour. Dept. Agr. and Tech. Instr. Ireland, 2 (1902), No. 3, pp. 511-514, figs. 2*).—Notes are given on the symptoms, etiology, and treatment of this disease. In outbreaks of sheep scab it is recommended that all affected and exposed sheep be dipped twice, with an interval of 10 days between the dippings; a third dipping may be necessary in some cases to render the treatment thoroughly effective. The desirability is suggested of dipping all sheep twice a year, once after shearing

and a second time in early winter, in order to prevent the development of an epizootic of sheep scab.

The vaccination of Algerian sheep and the control of sheep pox, E. NOCARD (*Bul. Agr. Algérie et Tunisie*, 8 (1902), No. 14, pp. 338-343).—A number of objections have been raised against the governmental procedure in combating sheep pox by means of the vaccination of Algerian sheep. These objections were that vaccination creates new foci of the disease and thus contributes to its spread in France. It was also argued that since the operation is not performed on all Algerian sheep there are some which are still subject to the disease and liable to cause serious outbreaks.

A number of writers have also combated the statement that epizootics of sheep pox are produced in France by the importation of Algerian sheep. These various objections are met by detailed arguments, and it is urged that the only measure which is calculated to effectively prevent the importation of sheep pox in France is general vaccination of all Algerian sheep.

The virulence of the wool of sheep affected with pox, after recovery and before being washed, L. DUCLERT and A. CONTE (*Ann. École Nat. Agr. Montpellier*, n. ser., 2 (1902), No. 1, pp. 52-56).—The literature relating to the infectiousness of the wool of sheep affected with pox is briefly discussed. A number of experiments were made for the purpose of determining how long the wool may be infectious, under various conditions. In one experiment a healthy sheep was confined with another sheep which had been inoculated 58 days previously, and had developed a generalized form of the disease 46 days previously. The pustules were still present in large numbers, and in a dried condition on the skin, and material from these pustules was also present on the wool. The healthy sheep did not become infected.

Blood poisoning (malignant edema) in sheep and lambs in New Zealand, J. A. GILBERTH (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901*, pp. 233-236).—Notes are given on the symptoms, cause, curative treatment, and prevention of this disease, which appears most frequently after some injury in shearing. The temperature is very high, extensive swellings appear on the under parts of the body, and death results in almost all cases. In preventing this disease the author recommends thorough disinfection of the soil in the localities where the disease appears regularly, and treatment of shearing wounds, especially when the latter are of a serious nature.

"Big head" of sheep in Utah (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901*, pp. 230-232).—A report was received from H. M. Rowe concerning a peculiar disease of sheep in Utah and Idaho. The first symptoms appear to be due to irritation of the lips. The gait soon becomes unsteady, and within about 45 minutes the animal becomes blind. The most conspicuous symptom is an extensive swelling of the head. Great difference of opinion prevails regarding the cause of the disease, but it is believed most probable that some poisonous plant is responsible for this trouble. It was not possible, however, to secure a specimen of the plant which shepherms suspect of being the cause of the disease.

Hog cholera (*Jour. Dept. Agr. and Tech. Instr. Ireland*, 2 (1902), No. 3, pp. 515, 516).—Attention is called to the importance of making prompt notification of the appearance of hog cholera. It then becomes possible for the proper officials to superintend the isolation of diseased hogs and the disinfecting of the premises.

A variety of the hog-cholera bacillus which closely resembles *Bacillus typhosus*, M. DORSET (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901*, pp. 566-571).—An organism was isolated from a hog during an outbreak of hog cholera in Iowa. The organism has been cultivated on artificial media for 18 months, and has undergone no perceptible variation. It stains readily with aqueous solutions of aniline dyes, but not by Gram's method. The bacillus is actively motile and possesses several flagella. No spores have been found. Notes are given on the behavior of this organism upon various nutrient media. It is pathogenic for hogs, rabbits, and guinea pigs. The only striking variation from the ordinary hog-cholera bacillus is its power of fermenting glucose without the production of gas.

Serum diagnosis of glanders, A. RABIEAUX (*Rec. Méd. Vét., Paris, 8. ser., 9 (1902), No. 12, pp. 303-309*).—In testing the value of serum reaction in the diagnosis of glanders the author recommends the following technical method: The serum to be examined was collected in as pure a condition as possible, and was then diluted in sterilized distilled water in proportions varying from 1:10 to 1:1,500. The diluted serum was then mixed with equal parts of a pure culture of glanders bacillus in peptonized or glycerinated bouillon. The mixture thus obtained was maintained at a temperature of 35 to 37° C., and examined at irregular intervals under a microscope. During these experiments it was found that at a temperature of 35 to 37° C. the 2 kinds of glanderous and nonglanderous serum possessed quite different agglutinating properties. When diluted in the proportion of 1:10 to 1:50, the difference in the agglutinating power of the 2 kinds of serum are quite manifest. Lower temperatures were found to have the effect of diminishing the rapidity and intensity of the agglutinating process. From the author's experiments it is reported that when a serum manifests a well-marked agglutinating power in a dilution of 1:1,000, the animal from which the serum was obtained should be considered glanderous. The method of serum diagnosis is essentially a laboratory method, and is not recommended as replacing other experimental methods which may be more convenient and satisfactory under certain circumstances.

A peculiar case of glanders in a horse in German Southwest Africa, RICKMAN and KÄSEWURM (*Arch. Wiss. u. Prakt. Thierh., 28 (1902), No. 1-2, pp. 142-152*).—A detailed description is given of a typical case of glanders in a horse, the usual symptoms of this disease being well developed. Not only did the clinical symptoms clearly indicate a case of glanders, but this diagnosis was strongly confirmed by a post-mortem examination. The altered lymphatic glands were found to contain large numbers of bacilli which agreed in all respects with the typical form of glanders bacillus. Pure cultures of these organisms showed the usual behavior of the glanders bacillus. However, in order to make the diagnosis more certain, inoculation experiments were made on guinea pigs, rabbits, and on the ass. All these experiments gave negative results. After the experimental animals had been inoculated for a sufficient length of time they were tested with mallein without showing a reaction, and were, later, killed and carefully examined post-mortem without finding any evidence of the development of glanders. The authors believe, nevertheless, that the original case was one of glanders, and by comparing the symptoms of the disease and the behavior of the bacilli, it appears that the possibility of the case having been pseudo-glanders is excluded.

An epizootic of herpes among young horses, FROEHNER (*Deut. Thierärztl. Wchnschr., 10 (1902), No. 1, pp. 1-3, fig. 1*).—The author described an extensive outbreak of this disease with special reference to the susceptibility of various races and colors of horses to infection. As a rule, the disease was for the most part confined to the shoulder. The parts which were next affected were the neck, flanks, and head. It was noticed that those parts of the skin which were protected by the long hair of the mane and tail were never affected, and it is suggested that the fungi which produce the disease may not be able to penetrate to the skin through long hair, or that the follicles of the long hair are more deeply located in the skin than those of the ordinary short body hair. Notes are given on a large number of remedies which have been recommended for the treatment of this disease, the most of which proved to be of little value. It is maintained that after infection has once taken place at a given point of the skin, epilation can not be prevented. Treatment should be restricted therefore to attempts to prevent the extension of the disease. Antiseptic salves should be repeatedly applied to the parts of the skin immediately surrounding the affected points.

Partial report upon the investigation of horse sickness, H. WATKINS-PITCHFORD (*Agr. Jour. and Min. Rec., 5 (1902), No. 13, pp. 397-401*).—The author has been

for some time investigating the nature and etiology of horse sickness in Natal. A number of doubtful points still remain to be elucidated, but observations thus far made indicate that a species of *Anopheles* is instrumental in transmitting the disease from one horse to another. A number of experiments were made in which mosquitoes were allowed to suck the blood of infected horses and were then allowed to suck the blood from the horses which were healthy. In all cases an elevation of temperature up to about 105.1° F. was observed, together with other symptoms of mild cases of horse sickness. The author was therefore inclined to believe that more work along this line will definitely prove the agency of this mosquito in transmitting the disease.

Latent parasitism and immunization against dourine, BUFFARD and SCHNEIDER (*Jour. Méd. Vét. et Zootech.*, 5. ser., 6 (1902), Mar., pp. 144-146).—From observations on asses and dogs the authors believe that the organism of dourine may persist in the affected animal for an indefinite time in a resistant form. This resistant form apparently plays the part of a spore. When the conditions are favorable for the germination of these resistant forms of the trypanosoma, the disease may suddenly break out in an acute form. The authors observed an attenuation of the virulence of the parasite in affected areas.

Acute epizootic leucoencephalitis in horses, W. G. MACCALLUM and S. S. BRUCKLEY (*Amer. Vet. Rev.*, 26 (1902), No. 1, pp. 21-36, figs. 7).—This paper in essentially the same form has been abstracted from another source (*E. S. R.*, 14, p. 91).

Diarrhea of new-born colts, E. THIERRY (*Jour. Agr. Prat.*, n. ser., 4 (1902), No. 31, p. 159).—Notes are given on the symptoms of infectious diarrhea, or diarrhetic enteritis in young sucking colts. In treating this disease it is recommended that the umbilical cord be washed with some antiseptic solution and that special attention be given to disinfection of stables in which the disease occurs.

The treatment of so-called colt lameness, A. MARCUS (*Berlin. Thierärztl. Wehnschr.*, 1902, No. 20, pp. 303-306, fig. 1).—While this disease is recognized as very prevalent in many parts of Germany, it is maintained that since the nature of the affection is known the disease may be controlled by suitable treatment. Attention should first be given to the stump of the navel cord, which should be rendered antiseptic and if necessary protected by bandages from contamination. When this treatment is carried out scrupulously infection can not take place and the later symptoms of lameness do not appear.

Petechial fever of horses, and its treatment by the serum of Marmorek (*Jour. Méd. Vét. et Zootech.*, 5. ser., 6 (1902), Mar., pp. 147-153).—Numerous experiments were conducted for the purpose of determining the action of Marmorek's serum in the treatment of this disease. Experiments with chemical remedies were without good results. The use of Marmorek's serum, however, gave good results in nearly all cases. The serum was injected in doses of from 10 cc. to 40 cc., and produced a lowering of the temperature and other observable improvement within a short time.

The treatment of morbus maculosus with the serum of contagious coryza streptococcus, O. SOMMERMEYER (*Deut. Thierärztl. Wehnschr.*, 10 (1902), No. 13, p. 123).—In the treatment of this disease quite unsatisfactory results were obtained from intravenous injections of colloidal silver preparations. A test was therefore made of a contagious coryza streptococcus serum recommended by Piorkowski. In applying this treatment, 10 cc. of immune serum was injected subcutaneously, and immediately afterwards 20 cc. of normal serum intravenously. As the result of this treatment the temperature was lowered, the appetite reappeared, and complete recovery took place within 10 days.

Contagious coryza and certain analogous diseases, CAGNY (*Rec. Méd. Vét.*, Paris, 8. ser., 9 (1902), No. 2, pp. 40-44).—The author states that in his immediate neighborhood contagious coryza is gradually becoming less frequent. Two other

diseases occur, however, which closely resemble it. In the case of one of these diseases abscesses are found in the walls of the nasal cavity, while in the other the most conspicuous symptom is violent fits of coughing. The cough is dry and of a hollow sound, and the animals cough 10 to 16 times in rapid succession. In one outbreak 50 animals were affected with this disease, and all recovered. Apparently no pathological lesions were produced. The author is unable to explain the physiology of these two affections.

Treatment of contagious coryza by colloidal silver, BAUMGART (*Berlin. Thierärztl. Wchnschr.*, 1902, No. 3, pp. 39, 40).—The author made an extensive test of the efficiency of this remedy in treating contagious coryza. The results were negative and in some instances indicated a harmful effect of the silver preparation. The author concludes that in slight cases of contagious coryza good results may be obtained without the use of colloidal silver, and that in more serious cases combined with sepsis or pneumonia, the colloidal silver exercises no beneficial effect upon the course of the disease.

Successful treatment of tetanus with a slow course by means of antitetanus serum, MARCHAL (*Rec. Méd. Vét., Paris, 8. ser.*, 9 (1902), No. 1, pp. 16-20).—Detailed notes are given on the symptoms of a case of tetanus in a mare 6 years of age. During an outbreak of conjunctivitis among horses the mare in question was observed to be affected with this disease. Recovery took place after a few days, and later, symptoms of tetanus appeared. At first 50 cc. of antitetanus serum was given in a hypodermic inoculation. Other injections of serum in similar doses were repeated. Various drugs were also administered, such as chloral hydrate in doses of 60 gm., bromid of potash in doses of 10 gm. night and morning, and morphin. Recovery took place 23 days after the appearance of the symptoms. No lesions were produced by the antitetanus serum at the point of inoculation.

A new method of cultivating the tetanus bacillus, L. DEBRAND (*Ann. Inst. Pasteur*, 16 (1902), No. 6, pp. 427-432).—The author made cultures of tetanus bacillus in symbiotic relation with *B. subtilis*. The association of the 2 species of bacilli in a single culture has the one practical advantage that when associated with *B. subtilis* the tetanus bacillus develops under aerobic conditions; otherwise, it is anaerobic. The serum of animals which have been immunized with a toxin prepared from mixed cultures of these 2 species of bacillus was tested in order to determine whether it possessed any antitoxic properties. Two series of experiments were conducted, in one of which animals received the serum before the toxin, and in the other, received the toxin before the serum. During these experiments it was found that a toxin obtained by a culture of tetanus bacillus in symbiosis with *B. subtilis* may be used to produce a serum in experimental animals which is as active as that obtained by the ordinary methods of cultivating tetanus bacilli.

The action of dry heat on the spores of tetanus bacillus, V. MORAX and A. MARIE (*Ann. Inst. Pasteur*, 16 (1902), No. 6, pp. 418-426).—The authors' experiments on this problem may be briefly summarized as follows: The tetanus bacillus was cultivated in symbiosis with *B. subtilis*. It was found that after heating cultures for 20 minutes at a temperature of 152° C. the spores of the tetanus bacillus were destroyed, while those of *B. subtilis* did not develop within 24 hours. A temperature of 155° C. for 20 minutes did not kill the spores of *B. subtilis*, while those of the tetanus bacillus were destroyed. Dry heat was found to reduce the vitality of the spores of tetanus bacillus and the virulence of the tetanus toxin in a rapid manner.

Glycosuria in rabies; its importance in diagnosing this disease, A. RABIEAUX and E. NICOLAS (*Jour. Méd. Vét. et Zootech.*, 5. ser., 6 (1902), Jan., pp. 16-28).—An extensive series of experiments was conducted by the authors for the purpose of determining how constant a symptom of rabies glycosuria could be considered. As a result of these experiments it was found that in carnivorous animals glycosuria is a very frequent symptom of rabies, but unfortunately is not constant enough to serve

as the only criterion for diagnosis. It is considered, however, that the presence of glycosuria is of great importance in the diagnosis of rabies when observed in connection with other suspicious symptoms. In dogs it is believed that the demonstration of glycosuria may be considered an important element in diagnosis. In herbivorous animals, such as rabbits, goats, and asses, the condition of glycosuria was found present in all cases of rabies, and this one symptom was therefore considered sufficient for determining the diagnoses of these animals. In herbivorous animals glycosuria may be recognized, not only after death, but during the progress of the disease.

Antirabies immunization by means of intravascular injections of rabies virus, V. KRASMITSKI (*Ann. Inst. Pasteur*, 16 (1902), No. 6, pp. 393-417).—An extensive series of experiments was conducted by the author on experimental animals, and these results are compared with phenomena observed during the progress of the disease in man and domesticated animals. As the result of the author's experiments it is concluded that intravenous injections of rabies virus are not dangerous, provided the virus is administered in a filtered, diluted emulsion, the emulsion to be previously heated to a temperature of 37° C. and injected slowly. By means of intravenous injection it is possible to render the animals refractory to rabies in a very short period, and the immunity thus produced appears to be more lasting and certain than that produced by other methods of vaccination. Intravenous injections made on rabbits sometimes prevented the development of the disease, even after intracranial inoculation of rabies virus. Rabid nerve virus rendered nonvirulent by any attenuating reagent does not possess an immunizing power. It may be used, however, as a vaccine, and when administered repeatedly in increasing doses renders animals less susceptible to the disease.

A new infectious disease in domesticated animals, A. AUJESZKY (*Centbl. Bakt. u. Par., 1. Abt., 32* (1902), No. 5, Orig., pp. 353-357).—During experimental investigations for the purpose of confirming a diagnosis on animals suspected of rabies a virus was isolated, which produced symptoms somewhat resembling those of rabies. It was found by a series of experiments that this virus was in the nature of a toxin, but all bacteriological tests were negative. An inflammatory condition developed at the point of inoculation within 36 to 48 hours, and the symptoms of the disease progressed rapidly from this time until the animal died, a few hours later. While the general symptoms of the disease resemble those of rabies, it can not be confused with the latter disease for the reason that the course of the disease is so rapid, the usual period being from 6 to 10 hours. The pathological alterations which are observed in carcasses of animals dead of the disease include hyperemia, minute hemorrhages in the internal organs and central nervous system, and distention of the alimentary tract.

Meningitis in dogs, C. CADÉAC (*Jour. Méd. Vét. et Zootech., 5. ser., 6* (1902), Apr., pp. 193-196).—The symptoms of this disease are said to be not very uniform. The cause of the disease is usually found in injuries to the eye and ear; the membranes of the brain and spinal cord may later show pathological lesions, as well as the eye and internal ear. The Eustachian tube may be filled with caseous or calcareous pus, and its walls may be thickened and much injected with blood.

Eczema rubrum of the dog, H. BÄR (*Schweiz. Arch. Tierh., 44* (1902), Nos. 1, pp. 1-18; 2, pp. 49-68, pls. 2).—The literature of this subject is reviewed in a critical manner in connection with a bibliography of 26 titles. The author found during his investigations that eczema rubrum is in no sense a developmental stage of another form of eruption, but is a specific disease of a parasitic nature due to a micrococcus of relatively slight virulence and resisting power. Apparently infection takes place in skin wounds. Not all dogs are susceptible to the disease. In addition to a certain predisposition, a long coat of hair seems to favor infection.

Ringworm in dogs, MATRUCHOT and DASSONVILLE (*Rec. Méd. Vét., Paris, 8. ser.,*

9 (1902), No. 2, pp. 50-71, pls. 3).—The authors present detailed account of the appearance, life history, and pathogenic action of 4 species of fungi which may cause ringworm disease of dogs. These species are *Trychophyton caninum*, *Eidamella spinosa*, a species of *Microsporum*, and *Oospora canina*. *T. caninum* is readily cultivated on the ordinary nutrient media. The optimum temperature is 27 or 28° C. *E. spinosa* is also easily cultivated and forms mycelia, perithecia, and chlamydospores. *T. caninum* is pathogenic for dogs and guinea pigs, while *E. spinosa*, according to the authors' experiments, was transmissible only to dogs. In these inoculation experiments the artificial disease differed to some extent from cases of natural infection.

Bothriocephalus latus in cats, B. GALLI-VALERIO (*Centbl. Bakt. u. Par.*, 1. Abt., 32 (1902), No. 4, Orig., pp. 285-287).—The author discusses the literature relating to the occurrence of this parasite in a cat. A number of doubtful cases have been reported, but the author believes that his observations demonstrate clearly that the species in question may occur in the cat. The economic bearing of this question is not discussed.

Death of domesticated animals attributed to bacterial cultures used for killing mice (*Izv. Min. Zem.*, 1 (1902), No. 14, pp. 296-298).—A number of cases of death among animals were reported as possibly due to bacterial cultures which had been distributed in the fields for the destruction of small rodents, especially mice. An investigation of the matter was made and from 961 replies to a circular letter it appears that there is no good evidence for supposing that bacterial cultures caused the death of domesticated animals. Epizootics were reported among cats, but the same disease occurred in places where no bacterial cultures had been distributed.—P. FIREMAN.

Fowl plague, E. CENTANNI (*Centbl. Bakt. u. Par.*, 1. Abt., 31 (1902), No. 4, Orig., pp. 145-152; No. 5, Orig., pp. 182-201, figs. 2).—A general historical account is given of the discovery and of outbreaks of this disease in various parts of Europe. The name fowl plague is given to distinguish it from fowl cholera, since investigations which the author has made indicate that the 2 diseases are distinct. The clinical symptoms are often not well marked, for the reason that the disease proves fatal in so short a period that the symptoms are not observed. Affected fowls refuse to take food and are rapidly overcome by extreme weakness and a tendency to sleep. The comb frequently assumes a violet color. In fowls dead of this disease the color of the skin is sometimes light and nearly normal, but often dark red and spotted. The meat possesses a dark color, but otherwise shows no abnormal conditions. The liver, spleen, and kidneys are enlarged, of a yellowish color, and more friable than in a normal condition. The pericardium is thickened and one of the most constant symptoms of the disease is a more or less marked pleuritis. The blood of affected fowls is exceedingly virulent; experiments showed that fatal infection might be produced by pricking the skin of healthy fowls with a needle which had been dipped in virulent blood. The disease ordinarily runs a fatal course in about 3 days. Experiments were made to determine the extent to which the virus would pass through various kinds of filters. In these experiments the Berkefeld and Chamberland filters were used. It was found that the virus readily passed through either of these filters and that the filtrate was virulent in minute doses. Detailed notes are given on the behavior of the organism on various culture media. It was found that the eggs from affected hens showed characteristic modifications. The albumen was more fluid, and the yolk more friable, pale, and permeated with white streaks. Such eggs were either absolutely infertile or produced embryos which died before the end of the incubation period. In some cases sickly chickens were hatched from them. Experiments indicated that the feces were infectious in chronic cases, but probably not, or only slightly infectious, in acute cases. It was found that the disease did not spread rapidly from one flock of fowls to another, except where healthy birds came in actual contact with affected ones. The resistance of the

organism to various physical and chemical disinfectants is not very striking. Ordinary chemical substances in the usual proportions and heat above 60° C. are sufficient to destroy the organism. The author presents a detailed comparison between the characteristics of the organism of fowl plague and those of pneumonia of cattle, South American horse disease, foot-and-mouth disease, diarrhea of young calves, etc. The dog and fox proved in experiments to be refractory to the disease. Inoculation experiments with rabbits were made with doubtful results. Pigeons appear not to be subject to natural infection and the virus was eaten by these birds without becoming infected. In a number of cases hypodermic injection of the virus of the disease in pigeons failed to produce any pathological symptoms. In a few young pigeons, however, a peculiar set of symptoms was produced, of which the most characteristic was the loss of equilibrating power and a tendency to fly or walk in circles, with evidences of dizziness.

Combating fowl cholera, BUHL (*Berlin. Thierärztl. Wchnschr.*, 1902, No. 13, pp. 193-197).—This article contains a general account of the nature and symptoms of fowl cholera, with special reference to the various means by which it may be disseminated. Attention is called to the statutory laws on this subject, according to which punishment is provided for carelessly or intentionally having any traffic in or moving about from place to place fowls which are affected with this disease. A bibliography of the subject is appended to the article.

Psittacosis, G. AJELLO and C. PARASCANDOLO (*Arch. Parasit.*, 5 (1902), No. 2, pp. 294-395).—The authors present an elaborate discussion of the symptoms and etiology of this disease, together with the appearance and behavior of the pathogenic organism and of the toxin obtained from pure cultures. The literature of the subject is discussed in connection with an extensive bibliography. The authors conclude from their experiments that the bacillus of psittacosis is specifically distinct and possesses specific morphological, physiological and biochemic properties. Filtered cultures are toxic for the ordinary experimental animals and the bacilli produce relatively slight lesions in rabbits and guinea pigs. By means of bacterial cultures it is possible to immunize rabbits and dogs, and the serum of these animals is endowed with a preventive and curative power against the disease.

The bacterial flora of the feces of fowls, together with notes on a new fowl plague, E. JOEST (*Berlin. Thierärztl. Wchnschr.*, 1902, No. 16, pp. 241-243).—Notes are given on numerous bacterial organisms which were found in the various parts of the alimentary tract and in the feces of fowls. An organism was isolated from a fowl suffering with a new form of infectious disease, and this organism is believed to be specifically different from all known bacteria. Notes are given on the staining affinities and the behavior of the organism in various nutrient media. The name adopted by the author for this organism is *Bacterium intestinale gallinarum*. The organism is non-motile and apparently does not form spores.

The significance of the recent American cases of hookworm disease (uncinariasis or anchylostomiasis) in man, C. W. STILES (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901*, pp. 183-219, figs. 84).—Notes are given on the occurrence of hookworm disease in this country, due to infestation by *Uncinaria duodenalis*. A detailed description is presented of this species, together with a brief account of related species which have been found in other domestic animals in this and other countries. The life history of the hookworm is given, together with an account of the source of infection, symptoms of the disease in man, its clinical diagnosis, treatment, and prevention. Abstracts are given of the various cases which have been reported in the United States and a bibliography of the subject is appended to the article.

The burning of dead animals, R. H. McDOWELL (*Nevada Sta. Bul. 53*, pp. 12).—Brief notes are given on the use of unslaked lime, which may be sprinkled upon diseased fowls in connection with burying them in the ground. Attention is called

to the desirability of making a safe disposal of the bodies of dead animals, especially those which die of infectious diseases. For this purpose it is considered that under farm conditions the safest method is to burn the bodies by means of direct fire produced by kerosene oil, wood, and other materials. The destruction of 2 animal bodies in this way cost \$1.56 and \$5.87, respectively. Notes are also given on the methods of disinfecting stalls and premises after outbreaks of infectious diseases.

Federal inspection of foreign and interstate shipments of live stock, D. E. SALMON (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901*, pp. 237-249).—Attention is called to the great development of the animal industry in this country and statistics are presented showing the number of cattle received at the stockyards and the numbers and value of animals exported to foreign countries. The author presents a number of forcible arguments to show the importance of maintaining federal quarantine and inspection in order to prevent the importation of other dangerous plagues into this country. The author calls attention to the service of the Bureau of Animal Industry in preventing the undue spread of tuberculosis, sheep scab, and other diseases.

Food products from diseased animals, D. E. SALMON (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901*, pp. 250-256).—Attention is called to the desirability of more extensive investigations regarding the effects upon man of eating meat of animals suffering with various diseases. The practices of federal meat inspection in this connection are briefly outlined. Animals suffering from wound septicemia or infested with bladder worms or trichina are condemned. In the case of tuberculosis, the carcass is condemned not only when emaciation is present but when lesions in the internal organs are so extensive as to indicate a serious stage of the disease. Brief notes are also given on the inspection of milk for the presence of tubercle bacilli.

Contagious diseases of animals in foreign countries (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901*, pp. 590-599).—Brief statistical notes on contagious diseases of animals in Great Britain, Russia, France, Germany, Hungary, Italy, Switzerland, Austria, Netherlands, Belgium, Denmark, Norway, and Sweden.

Report of the veterinarian, A. T. PETERS (*Nebraska State Bd. Agr. Rpt. 1901*, pp. 151-190, figs. 15).—In this report notes are given on sorghum poisoning of cattle, sore mouth of cattle, kidney diseases in horses, paralysis of the hind limbs of hogs, mange in cattle and horses, lice on hogs, and a paper on tuberculosis in swine, by S. Stewart.

Reports of inspectors of stock, H. R. MACKENZIE, W. J. COTHER, and J. E. BATCHELOR (*Jour. Dept. Agr. Victoria*, 1 (1902), No. 3, pp. 338-344).—Brief notes are given on the occurrence and prevalence of various diseases in different parts of Victoria. It is stated that tuberculosis is stationary, or at least not on the increase. The heaviest losses are reported from blackleg in young cattle. A verminous lung disease caused by some species of threadworm is reported as having prevailed to a serious extent. In certain parts of the country pleuro-pneumonia occurred in outbreaks of considerable extent. The "yambuk" disease is also reported as having caused the death of large numbers of cattle.

Statistics concerning the number of animals slaughtered and the number found diseased in the Prussian abattoirs during the year 1900 (*Berlin. Tierärztl. Wchnschr.* Nos. 17, pp. 253-259; 18, pp. 265, 266).—These extensive statistics are compiled in a manner so as to show the number of animals killed and the number affected with the more important diseases, including tuberculosis of cattle and hogs, beef measles, pork measles, and trichina.

Text-book of veterinary medicine, IV, J. LAW (*Ithaca, N. Y.: Author, 1902*, pp. 675).—This volume of the author's text-book on veterinary medicine is occupied with an account of infectious diseases. Each disease is discussed in a thorough manner and the most recent work on the subject is adequately considered in connection with all discussions. The most important diseases considered in this volume are

pyemia, septicemia, malignant edema, swine erysipelas, hog cholera, swine plague, hemorrhagic septicemia, strangles, pneumonia in horses, influenza, petechial fever, fowl cholera, distemper in dogs and cats, blackleg, anthrax, glanders, rabies, tetanus, foot-and-mouth disease, milk sickness, variola, contagious abortion, tuberculosis, South African horse sickness, dourine, surra, nagana, Texas fever, ictero-hematuria in sheep, pleuro-pneumonia, and cattle plague.

The veterinary adviser: On the symptoms and treatment of the diseases of domestic animals, B. SCHMIDT (*Piqua, Ohio: Mugee Bros., 1902, pp. 148*).—In this volume the author presents formulas as remedies for the various diseases of domestic animals, especially the horse. The diseases are classified according to the organs affected. A brief list of diseases is also appended to the volume, with recommendation of a prescription for each disease.

TECHNOLOGY.

Manufacture of table sirups from sugar cane, H. W. WILEY (*U. S. Dept. Agr., Bureau of Chemistry Bul. 70, pp. 32, pls. 10, figs. 2*).—An account of this industry in the South is based upon personal inspection by the author in Georgia. Notes are given on a large number of soil samples together with chemical and mechanical analyses. The soils represented were almost pure sand and showed a deficiency in potash soluble in hot hydrochloric acid, and to a less extent a deficiency in phosphoric acid. Analyses of numerous samples of sugar cane are also reported, which show a high average percentage of sucrose and usually a low quantity of reducing sugar. Although there are a large number of samples of fine quality, the average coefficient of purity does not quite reach the desired standard of 80. Some of the problems needing further study are the character and adulteration of the sirups now on the market, the use of fertilizers in the culture of sugar cane, the improvement of milling processes, the methods of clarifying and purifying the juice previous to its evaporation, and the production of a sirup of uniform character and its handling to prevent fermentation. The arrangement of a sirup factory with modern appliances is outlined.

The manufacture and preservation of unfermented grape must, G. C. HUSMANN (*U. S. Dept. Agr., Bureau of Plant Industry Bul. 24, pp. 19, pl. 1, figs. 4*).—This bulletin, after referring to the ancient use of unfermented wine, briefly discusses the composition of the grape and the causes and prevention of fermentation, and describes the methods of making unfermented grape must followed in California (*E. S. R., 12, p. 794*) and in the Eastern States; outlines a simple method of manufacture for home use; and explains the various uses of the product, with recipes, analyses of the must, and prices and statistics.

Report on wine making experiments at the Gard œnologic station in 1901, E. KISER and G. BARBA (*Bul. Min. Agr. [France], 21 (1902), No. 2, pp. 305-321*).—

Changes in the chemical composition of bilberry wine after three and one-half years, R. OTTO (*Proskauer Obstbau-Ztg., 7 (1902), No. 7, pp. 98-100*).—Analyses are given showing the composition of wine fermented with pure yeast cultures, with and without additions of different nitrogenous combinations, like crystallized asparagin, ammonia, ammonium chlorid, etc. The wine was analyzed when first made, and again 3½ years later.

A contribution to a knowledge of the chemistry of cider, A. H. ALLEN (*Analyst, 27 (1902), No. 315, pp. 183-190*).—This paper includes original analyses of apples, apple pulp, typical English ciders, and perry.

Experiments on cider making, report for 1901, F. J. LLOYD (*Jour. Bath and West and South. Counties Soc., 4. ser., 12 (1901-2), pp. 131-149*).

The society's 1901 exhibition of cider, F. G. FARWELL (*Jour. Bath and West and South. Counties Soc., 4. ser., 12 (1901-2), pp. 150-167*).

Observations on the production of vinegar in cellars, W. B. ALWOOD and R. J. DAVIDSON (*Virginia Sta. Bul.* 127, pp. 61-71).—A further preliminary study is given on the production of vinegar under ordinary farm conditions (E. S. R., 9, p. 1094). Casks holding 50 gal. each were filled with fresh cider on different dates and stored in an ordinary underground cellar having a temperature ranging from 50 to 60° F. A record is given of the chemical changes that took place in the conversion of the sugar to alcohol and the alcohol to acetic acid. The cider thus stored reached its maximum alcohol content in from 23 to 44 days after placing in the cellar. It required from 350 to 418 days' storage before the acetic acid content had reached $3\frac{1}{2}$ per cent. Vinegar analyzing less than $3\frac{1}{2}$ per cent is stated to be too weak to put on the market. Very good vinegar was produced in every instance, but the system is not recommended when vinegar is made in sufficient quantity to warrant a generator.

Parallel with this experiment, 3 series of flasks were filled with 200 cc. each of sterilized cider and kept in a culture oven ranging from 80 to 82° F. for periods varying from 2 to 12 days. One series of flasks was sown with a drop of strong yeast culture. Another series was seeded with the yeast and in addition with a drop of vinegar ferment (*Bacterium aceti*). The tabular record of analyses given shows that no acetic acid was formed in the flasks during alcoholic fermentation. In one series the vinegar ferment was added at the end of 16 days, at which time alcoholic fermentation had apparently subsided. The formation of the acetic acid in these flasks did not take place in a regular increasing ratio in accordance with the time elapsing after adding the ferment. This was owing, it is thought, to the absence of sufficient oxygen in the flasks.

New process in olive-oil making (*California Fruit Grower*, 27 (1902), No 761, p. 13).—It is stated that by the use of centrifugal force from machines similar to the modern sugar house centrifugal machine, 10 per cent more olive oil has been obtained.

Tanning materials, G. E. COLBY (*California Sta. Rpt.* 1899-1901, pt. 2, pp. 255-259).—Analysis are reported of 25 samples of canaigre roots and chips, 15 of wattle barks, 3 of oak tan barks, 1 of Chinese gall nuts produced by *Aphis chinensis* in leaves of *Rhus semialata*, and 2 of commercial tannin.

The average results of the analyses of canaigre show a tannin content of 30.6 per cent. Experiments conducted to determine the production of tannin in plants grown from different sections of canaigre root showed that the greatest increase in tannin yield is obtained by planting the upper section of the root. In these tests when the whole root was used the tannin in the new growth was 8,680 times that found in the seed root, and when the top section alone was used the tannin of the new growth was 29,305 times that of the original section.

The results of analyses of the wattle barks produced at the Santa Monica Station have already been noted (E. S. R., 12, p. 995). Analyses of the bark from black wattle trees grown at Berkeley showed 41.40 and 50.05 per cent tannin in the air-dried substance. The bark from the main trees, branches, and large roots of the silver wattle showed, respectively, 35.53, 31.87, and 34.48 per cent of tannin. The bark from golden wattle trees showed 41.60 per cent tannin.

Textile fibers of commerce, W. I. HANNAN (*London: Charles Griffin & Co.*, 1902, pp. 236, ill.).—A handbook on the occurrence, distribution, preparation, and uses of the animal, vegetable, and mineral fibers used in cotton, woolen, paper, silk, brush, and hat manufactures.

Chemical technology of textile fibers—their origin, structure, preparation, washing, bleaching, dyeing, printing, and dressing, G. VON GEORGEVICS, trans. by C. SALTER (*London: Scott, Greenwood & Co.*, 1902, pp. 306, figs. 47).

The art of paper making, A. WATT (*London: Crosby Lockwood & Son*, 1901, 2. ed., pp. XII + 260, figs. 86).—This contains chapters on cellulose; materials used in

paper making; treatment of rags; treatment of esparto; treatment of wood; treatment of various fibers; bleaching; beating or refining; loading, sizing, coloring; making paper by hand; making paper by machinery; calendering, cutting, and finishing; colored papers; miscellaneous papers; machinery used in paper making; recovery of soda from spent liquors; determining the real value or percentage of commercial sodas, chlorid of lime, etc.; useful notes and tables; and a list of papers on paper making.

A new paper stock (*Tradesman*, 48 (1903), No. 10, p. 67).—The successful use at Niagara Falls of cotton hulls as stock for ordinary "writing" and "news" grades of paper is noted.

AGRICULTURAL ENGINEERING.

Report of irrigation investigations for 1901, E. MEAD ET AL. (*U. S. Dept. Agr., Office of Experiment Stations Bul. 119, pp. 401, pls. 64, figs. 12*).—This is the third annual report on irrigation investigations (E. S. R., 13, p. 999), and includes a summary of results by R. P. Teele, and reports by special agents and observers as follows: Irrigation in New Mexico, by W. M. Reed; Irrigation Investigations in the Salt River Valley for 1901, by W. H. Code; Irrigation at the Arizona Experiment Station Farm, by A. J. McClatchie; Studies of the Subterranean Water Supply of the San Bernardino Valley and Its Utilization, by E. W. Hilgard; Duty of Water under Gage Canal, Riverside, Cal., 1901, by W. Irving; Duty of Water in Tule River Basin, California, by A. E. Chandler; The Use of Water in Irrigation in Washington for the Season of 1901, by O. L. Waller; The Distribution of Water from Canals in Idaho, by D. W. Ross; Irrigation Investigations in Montana, 1901, by S. Fortier; Irrigation in Bear River Valley, Utah, 1901, by A. P. Stover; Irrigation in the Grand Valley, Colorado, 1901, by A. P. Stover; Irrigation in the Arkansas Valley, Colorado, by A. P. Stover; Irrigation under the Great Eastern Canal, Platte County, Nebr., in 1901, by O. V. P. Stout; Irrigation Experiments at the Missouri Experiment Station, by H. J. Waters; Irrigation Experiments in Wisconsin, by F. H. King; Irrigation in New Jersey, by E. B. Voorhees; Second Progress Report on Silt Measurements, by J. C. Nagle.

The investigations reported deal mainly with the duty of water in irrigation and the methods and measures for securing the largest and best use of the water supply, but take up incidentally many other related questions. "In the measurements so far made no attempt has been made to control the quantity of water used. The attempt has been to find out how much water is used under present practice. . . . It is the intention to make the investigations of the future deal more and more with what can be done by better methods and more economical use of water."

The results reported show a wide difference between the amount of water entering the main canals and that actually received by the land. Thus, averaging all the measurements of water received by the main canals, it appears that the following quantities of water were used per acre: In 1899, 4.42 acre-feet; 1900, 4.08 acre-feet; 1901, 4.90 acre-feet; average, 4.45 acre-feet. The quantity used, as measured at the heads of the laterals and on the farms, is shown to be in the cases recorded from 30 to 40 per cent less, which represents the loss "between the heads of canals and the place of use, on the assumption that the measurements are representative." The average loss of water from canals was, according to the 1901 measurements, 1.45 per cent per mile, as against 2.47 per cent the previous year. The percentage loss is shown to decrease as the size of the canal increases. Thus the loss from canals carrying 100 cu. ft. per second or more was 0.98 per cent per mile, 50 to 100 cu. ft. per second 2.67 per cent, 20 to 50 cu. ft. 5.22 per cent, less than 25 cu. ft. 7.48 per cent.

The data for duty of water with different crops show, as would be expected, wide

variations. Averages of the observed duty for a few crops, with the period during which they require water, are given in the following table:

Water required by different crops, and the irrigating season for each.

Crop.	Depth of irrigation.	Irrigating season.
	<i>Feet.</i>	
Potatoes	3.94	May 17 to Sept. 15.
Alfalfa	3.39	Apr. 1 to Sept. 22.
Orchard	2.76	Apr. 15 to Sept. 2.
Wheat	2.68	Apr. 1 to July 26.
Sugar beets	2.15	July 13 to Aug. 17.
Oats	1.73	May 22 to Aug. 29.
Barley	1.49	June 12 to Aug. 1.
Corn	1.40	July 24 to July 28.

"The average depth given for wheat is undoubtedly too large, on account of the excessive quantities used in Nevada. The season for sugar beets, as given in the table, refers to Montana alone, and is too short for States farther south. It should be extended at least to September 1. Making these allowances, the table shows that in general the crops requiring the most water have the longest seasons. The statements made in this table are of value as showing what crops can be raised with a given water supply. The grain crops require the least water, and require it at a season of the year when the streams supply the most. Orchards, potatoes, alfalfa, and sugar beets require water during the season when the flow of streams is at a minimum, and hence only small areas of these crops can be raised without storing water. On the other hand, these crops give much larger returns than the grain crops."

The report contains summaries of the progress made in experiments with irrigation in the humid region—Nebraska, Missouri, Wisconsin, New Jersey—and of observations on pumping water for irrigation, which are of special interest.

"The measurements of the quantities of water used and lost, and the savings made by the adoption of regulations under which farmers pay for the quantity of water they receive, give reason to believe that the present canals and the existing water supply can be made to serve at least double the area now farmed, with a possibility of still further economies and a further development."

What the Department of Agriculture is doing for irrigation, E. MEAD (*U. S. Dept. Agr., Office of Experiment Stations Circ. 48, pp. 4*).—A brief outline.

Water supply and irrigation in Nevada, L. H. TAYLOR (*Nevada Sta. Bul. 52, pp. 64, pls. 12, maps 3*).—This bulletin discusses the general topographic features of Nevada, precipitation—rain and snow—run off, evaporation, character of streams, subsurface waters, seepage waters, and water storage, with a detailed account of the investigations of the U. S. Geological Survey on the water supplies of the Truckee, Carson, Walker, and Humboldt rivers and other streams. The extent, methods, and possibilities of irrigation in the State are also briefly discussed.

"At the present time probably not less than 325,000 acres of land from which crops are harvested are under water, and nearly if not quite as much more are irrigated for pasture purposes. While it is not possible to state just where these lands are, it is safe to say that fully half are on the Humboldt River and its tributaries, about one-fourth on the Truckee, Carson, and Walker rivers, and the remainder scattered over the State, generally in small tracts and in isolated localities. Of the cropped area it is estimated that fully one-half is devoted to the production of native grasses for hay, while perhaps over half of the remainder is in alfalfa and other forage crops, and the balance, or about 80,000 acres, is employed for the production of cereals and general farm produce. . . .

"In general the methods of applying water to the growing crops are the most crude. . . . All over the State there is a general lack of system, not only in the

practicable application of the water to the soil, but in the administration where community interests exist. There is no attempt on the part of the State to exercise supervision or control of its appropriation and use, and the inevitable result of such neglect, wastefulness, confusion, undefined rights, and, in times of scarcity, litigation, are everywhere apparent. . . .

"The probabilities are that the average duty of water the State over at the present time is somewhere from 60 to 100 acres per second-foot. . . . There is no reason, beside absolute wastefulness in methods of conveying and applying water, why the average duty should not be at least 150 acres per second-foot for the entire State of Nevada."

It is estimated that with improved methods the irrigated area might be increased to 1,000,000 acres, but this would make the need of storage more imperative. The author concludes from his investigations that it is feasible "to construct in the upper portion of the Truckee River basin seven storage reservoirs, with a gross capacity of 835,168 acre-feet, from which there can be drawn annually 288,768 acre-feet," and "that the watersheds tributary to these reservoirs yield sufficient water, even in seasons of minimum precipitation, to fill each of them." He also believes it feasible "to construct in the basin of Carson River five storage reservoirs, with a total capacity of 274,300 acre-feet."

Water storage in the Truckee Basin, California-Nevada, L. H. TAYLOR (*Water Supply and Irrig. Papers, U. S. Geol. Survey, No. 68, pp. 90, pls. 8, figs. 20*).—The results of surveys and examinations are reported which show that "by constructing various dams and other hydraulic works a large amount of water which now runs to waste can be saved and conducted out upon vacant public land, furnishing a supply also to some of the lands now in private ownership." The author's conclusions regarding the storage possibilities of this basin are stated in the abstract of the bulletin on Water Supply and Irrigation in Nevada given above.

Irrigation systems of Texas, T. U. TAYLOR (*Water Supply and Irrig. Papers, U. S. Geol. Survey, No. 71, pp. 137, pls. 2, figs. 27*).—This is a revised and enlarged edition of an earlier bulletin on this subject (E. S. R., 11, p. 94). "In the present report Professor Taylor has discussed the principal irrigation systems in general geographic order, and has given statistics as to the location, cost, and benefits of the devices for obtaining water. He has also devoted some attention to the irrigation of rice, a business in which large amounts of capital are being invested. There has been appended a brief statement of the laws governing irrigation in the State of Texas, also some of the facts obtained from the recent census investigation."

Irrigation from Big Thompson River, J. E. FIELD (*U. S. Dept. Agr., Office of Experiment Stations Bul. 118, pp. 75, pls. 6, fig. 1*).—This is a study of the operation of the water laws of Colorado as illustrated by the irrigation from Big Thompson River. The author gives particular attention to the so-called "water-loaning" law, a recent enactment which has a tendency to unsettle existing rights.

Geology and water resources of the Patrick and Goshen Hole quadrangles in eastern Wyoming and western Nebraska, G. I. ADAMS (*Water Supply and Irrig. Papers, U. S. Geol. Survey, No. 70, pp. 50, pls. 11, figs. 4*).—This report is largely geologic in character, but "deals with some of the problems of water supply for this area and discusses conditions which are to be found over a considerable part of the public-land area," including data regarding irrigation; timber, grass, and agricultural products; settlement and occupancy of public lands; and an appendix giving the desert-lands and Carey acts, and an act providing for the construction of reservoirs on public lands for watering stock.

Report of the engineer, O. V. P. SROUT (*Nebraska State Bd. Agr. Rpt. 1901, pp. 143-150*).—The main feature of this report is a statement of stream measurements made in cooperation with the U. S. Geological Survey, including tables showing the ratio of maximum to minimum monthly discharge (May-September, 1895-1900) of

the Loup, North Platte, Poudre, and Arkansas rivers; the daily discharge in 1901 of the Platte River at Mitchell and Columbus, the Loup at Columbus, the Elkhorn at Norfolk and Arlington, the Republican at Superior; as well as miscellaneous stream measurements. Measurements of the quantity of water used in irrigation as already reported in bulletins of this Office are referred to.

Irrigation in the western division, J. WRIGHT (*Agr. Gaz. New South Wales*, 13 (1902), No. 11, pp. 1108-1112).—A brief discussion of water supply, soils, crops, water requirements of crops, and methods of application of water in this district of New South Wales.

Some features of irrigation, W. O. WEBBER (*Engineer Rec.*, 47 (1903), No. 2, p. 57).—This is a discussion, from an engineering standpoint, of the importance of a careful preliminary consideration of rainfall, run off, and duty of water in the construction of irrigation works—reservoirs, ditches, head gates, and flumes.

Waterpowers of the State of Maine, H. A. PRESEY (*Water Supply and Irrig. Papers, U. S. Geol. Survey*, No. 69, pp. 124, pls. 14, figs. 12).

Water-supply notes (*Country Gent.'s Estate Book*, 1902, pp. 207-210).—Data are given in form of tables and notes on the purity of water, water pressure, measurement of the volume of streams, flow of water from reservoirs, hydraulic runs, cost of pumping, volume and weight of water per acre, power required to raise water from deep wells by means of pumps, evaporation and seepage from reservoirs, etc.

The laws of Indiana for constructing ditches and levees, 1901 (*Indianapolis: Indiana General Assembly*, 1901, pp. 107-XX).—A compilation of laws relating to drainage of lands and towns, including those enacted in 1901.

Land drainage (*Country Gent.'s Estate Book*, 1902, pp. 203, 204).—Tabular data are given regarding cost of drainage, weight of drainpipes, number of tiles required per acre, depth of drains, discharge of pipes, rainfall removed by drainage, depth of roots of farm crops, etc.

The bacterial disposal of sewage from country houses, G. J. G. JENSEN (*Country Gent.'s Estate Book*, 1902, pp. 179-182).—A brief discussion of the applicability of this method of sewage disposal to rural conditions.

Sewage pollution in the metropolitan area near New York City and its effect on inland water resources, M. O. LEIGHTON (*Water Supply and Irrig. Papers, U. S. Geol. Survey*, No. 72, pp. 75, pls. 8, figs. 4).

The adaptation of the peat-closet system to medium-sized and smaller towns, FRAENKEL, PFEIFFER, and WITT (*Arch. Deut. Landw. Gesell.*, 1902, No. 74, pp. 76, figs. 23).—The subject is discussed from the agricultural, sanitary, and technical standpoints. A report by H. von Feilitzen on the use of the method in Swedish towns is given in an appendix.

Road conventions in the Southern States, and object-lesson roads constructed under the supervision of the Office of Public Road Inquiries with the cooperation of the Southern Railway (*U. S. Dept. Agr., Public Road Inquiries Bul.* 23, pp. 89, pls. 11).—This is an account of an expedition for promoting road-making and for building object-lesson roads in the Southern section of the United States, starting at Alexandria, Va., October 29, 1901, and ending at Charlottesville, Va., April 5, 1902. During this time 4,037 miles were covered and object-lesson roads were built at 18 different places, namely, Winston-Salem, Asheville, and Raleigh, N. C.; Greeneville and Chattanooga, Tenn.; Birmingham, Mobile, and Montgomery, Ala.; Atlanta, Columbus, and Augusta, Ga.; Greenville, Columbia, and Charleston, S. C.; Lynchburg, Danville, Richmond, and Charlottesville, Va. An account of the proceedings and the papers read at meetings held in the interests of good roads at these places are given.

Wind power notes (*Country Gent.'s Estate Book*, 1902, p. 211).—Data are given regarding velocity and force of wind, capacity of windmills, power developed by windmills, pumping capacity of windmills, etc.

Engine power notes (*Country Gent.'s Estate Book*, 1902, pp. 205, 206).—The relative merits of steam, gas, hot air, and oil engines are discussed, and data are given regarding the comparative cost of motor power, horsepower of engines, cost of steam haulage and of steam digging.

Electric power on German farms (*Farm Machinery*, 25 (1902), No. 574).—A brief note calling attention to the large use of electric power for agricultural purposes—for driving thrashing machinery, pumps, hay presses, straw cutters, etc.

The transportation of manure over uneven ground, H. DUPAYS (*Jour. Agr. Prat.*, n. ser., 5 (1903), No. 2, pp. 49-51, figs. 3).—An arrangement of pulleys, cables, and cars for this purpose is described.

The American plow and the Russian farmer, T. E. HEENAN (*U. S. Consular Rpts.*, 70 (1902); No. 266, pp. 317-324, figs. 8).—A brief description is given of some of the principal kinds of plows in common use in Russia, with suggestions as to how American manufacturers may adapt their implements to Russian tastes and conditions.

Development of the disk plow (*Farm Machinery*, 25 (1902), No. 574, figs. 12).—The history of the development of the disk plow is briefly reviewed and the characteristic features of a number of different makes are described.

The Derby land digger (*Jour. Khediv. Agr. Soc. and School Agr.*, 4 (1902), No. 6, p. 232).—This steam cultivator, recently put on the market in England, is briefly described and its work commended.

The reaping machine (*Farm Machinery*, 25 (1902), No. 571).—A brief note on the reaping machine invented by John Common, of Denwick, England, in 1811.

A sifting machine for grading oats and freeing grains from ergot, H. WALTER (*Füßling's Landw. Ztg.*, 54 (1902), No. 24, pp. 887-892).

Comparative tests of seed cleaning and sorting machines (*Deut. Landw. Presse*, 29 (1902), No. 97, p. 787).

Notes on the building of stables and farmsteads, E. S. WILSON (*Country Gent.'s Estate Book*, 1902, pp. 193-197, figs. 5).—Plans for stables and farmsteads are briefly discussed.

The heating of poultry houses (*Deut. Landw. Presse*, 30 (1903), No. 2, pp. 13, 14, figs. 7).—Methods followed especially in the United States are briefly described.

The utilization of waste products, T. KOLLER (*London: Scott, Greenwood & Co.*, 1902, pp. VIII+279, figs. 22).—This is termed "a treatise on the rational utilization, recovery, and treatment of waste products of all kinds." Among the waste products which are discussed are many which are of agricultural importance as fertilizers, feeding stuffs, etc., such as town waste, blood and slaughterhouse refuse, tannery and leather wastes, excrement, slag, fish waste, brewers' waste, molasses, etc., but their utilization in agriculture is only briefly referred to.

MISCELLANEOUS.

Report of California Station, 1899-1901 (*California Sta. Rpt. 1899-1901*, pt. 2, pp. IV+145-409).—This contains introductory notes by E. W. Hilgard on instruction in the college of agriculture, numerous articles abstracted elsewhere, lists of exchanges and station publications, and revised reprints of articles or more detailed accounts of work on water (E. S. R., 14, p. 229), olives (E. S. R., 14, p. 441), and feeding sugar-beet pulp (E. S. R., 13, p. 481).

Annual Report of Pennsylvania Station, 1901 (*Pennsylvania Sta. Rpt. 1901*, pp. 439).—This contains the organization list of the station; a financial statement for the fiscal year ended June 30, 1901; a report of the director reviewing the different lines of station work, mentioning the needs of the station and enumerating new lines of work; and departmental reports containing articles noted elsewhere. The following articles in essentially the same form or abridged have been noted from other

sources: The complete analysis of feeding materials (E. S. R., 13, p. 320), the determination of sulphur and phosphorus in plant substances (E. S. R., 14, p. 417), methods of dairy feeding (E. S. R., 13, p. 779), the effect of smoke and gas upon vegetation (E. S. R., 13, p. 527), and the agricultural seed supply of Pennsylvania (E. S. R., 13, p. 653).

Annual Reports of the Department of Agriculture, 1902 (*U. S. Dept. Agr. Rpts. 1902*, pp. CXIV + 402).—This includes the report of the Secretary and the chiefs of the different bureaus and divisions on the work of the Department during the year. The report of the Secretary is also published as Report No. 73 of the Department.

Eighteenth Annual Report of the Bureau of Animal Industry, 1901 (*U. S. Dept. Agr. Bureau of Animal Industry Rpt. 1901*, pp. 706, pls. 117, figs. 210).—This includes a report of the chief of the Bureau reviewing the different lines of work during the year, 22 articles noted elsewhere in this issue, and 6 articles already noted from other sources as follows: Emergency report on surra (E. S. R., 14, p. 192); further investigations on verminous diseases of cattle, sheep, and goats in Texas (E. S. R., 13, p. 593); statistics of oleomargarine, oleo oil, and filled cheese, 1900-1901 (E. S. R., 13, p. 990); market classes of horses (E. S. R., 13, p. 1081); mohair and mohair manufactures (E. S. R., 14, p. 383), and the use of eggs as a medium for the cultivation of *Bacillus tuberculosis* (E. S. R., 14, p. 611). Brief articles are included on the following subjects: The horse trade of the United States with foreign countries, sheep feeding in Nebraska, the sheep-scab mite and low temperature, work of the Bureau of Animal Industry indorsed, live stock in Russian Empire, imports of cattle and sheep by Great Britain, wool exports from Montevideo, Arabian wool trade, egg industry in Denmark, eggs in Spain, egg production, and milk flour in Sweden. Statistics are given on the number and values of farm animals in 1900, pork packing in the United States, and receipts and shipments of live stock during 1901. The rules and regulations of the Bureau of Animal Industry issued in 1901 conclude the volume.

Imports and exports of animals and animal products, J. ROBERTS (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1901*, pp. 611-637).—A statistical review for the year 1901.

Annual report of the Bureau of Industries for the Province of Ontario, 1901 (*Toronto: Ontario Dept. Agr., 1902*, pp. 46).—This includes meteorological observations, crop reports, and other statistical matter.

Annual Report of the Department of Agriculture of the Northwest Territories, 1901 (*Rpt. Dept. Agr. Northwest Territories, 1901*, pp. 186).—A general report on meteorological and agricultural conditions, live stock, colonization, agricultural education, public health, etc., in the Northwest Territories.

Report on agriculture, P. GENNADIUS (*Cyprus Dept. Agr. Rpt. 1901-2*, pp. 19).—The following subjects are treated in this account of agriculture in Cyprus: Agricultural implements and machinery, olive-oil industry, nurseries, silkworm rearing, essential oils, diseases of plants, underground waters, and irrigation with reservoir waters.

Industrial progress in North Carolina (*Bul. North Carolina State Bd. Agr., 23 (1902), No. 7*, pp. 40).—Gives lists of cotton, woolen, and silk mills and other industries, and cattle, horse, swine, sheep, goat, and poultry registers.

History of German agriculture, T. VON DER GOLTZ (*Geschichte der deutschen Landwirtschaft. Stuttgart and Berlin: J. G. Cotta, 1902, vol. 1*, pp. 485).—This first volume treats of German agriculture from the time of the earliest records on the subject to the close of the Eighteenth Century. The social and economic conditions of the country at different periods are discussed, and special attention is given to the development of agriculture during the last 50 years of the Eighteenth Century as affected by legislation, the progress of natural science, and improvements in soil cultivation and farm management.

Agricultural and viticultural calendar, V. VERMOREL (*Agenda agricole et viticole. Montpellier and Villefranche (Rhône): Bibl. Prog. Agr. et Vit., 1903, pp. 333*).—This calendar, which is the eighteenth of the series, gives a large amount of information in a condensed form which is of value to the agriculturist and viticulturist. Considerable attention is given to the subject of plant diseases and insect enemies, with suggestions for their control.

The country gentlemen's estate book, 1902, W. BROOMHALL (*London: The Country Gentlemen's Association, Ltd., 1902, pp. VI + 600*).—This book is the coronation edition of the tenth yearbook of the Country Gentlemen's Association. It contains articles on different phases of farm management and many useful notes and memoranda for landowners and farmers, a number of which are noted elsewhere.

Timely hints for farmers (*Arizona Sta. Bul. 45, pp. 215-238, figs. 5*).—This contains reprints of press bulletins issued separately by the station from October 15, 1901, to June 10, 1902, on the following subjects: Something worth knowing about mud, legumes for forage and green manuring, sugar beets, the dairy cow and the weather, extermination of gophers and ants, the rise of the alkali, and *Lippia nodiflora* (see p. 657).

Secondary courses in agriculture, A. C. TRUE ET AL. (*U. S. Dept. Agr., Office of Experiment Stations Circ. 49, pp. 10*).—This is an extract from the seventh report of the committee on methods of teaching agriculture of the Association of American Agricultural Colleges and Experiment Stations. Cooperation is urged between country districts, villages, cities, and the State to provide means for the maintenance of agricultural courses in high schools. It is believed that the courses of study now in use in most high schools could be easily modified so as to include agriculture as a part of the course. One additional teacher would be necessary for this work, who should if possible be a graduate of some agricultural college. The present programmes for high schools in Indiana, Lowell, Mass., Des Moines, Iowa, and Washington, D. C., are given, with the number of recitation periods per week for each subject. Based on these programmes parallel columns are given showing tentative agricultural courses. It is believed that it would be entirely practicable to so adjust the present high school schedules as to make the teaching of agriculture in these schools fairly satisfactory.

Proceedings of the seventh annual meeting of the American Association of Farmers' Institute Workers (*U. S. Dept. Agr., Office of Experiment Stations Bul. 120, pp. 119*).—This is a detailed account of the proceedings, edited by A. C. True, D. J. Crosby, and G. C. Creelman, a summary of which has already been given (*E. S. R., 13, p. 1110*).

Report of the Farmers' Institutes of the Province of Ontario, 1901 (*Toronto: Ontario Dept. Agr., 1902, pt. 1, pp. 128, figs. 25*).—This includes a brief account of farmers' institute work in Ontario and numerous papers and discussions.

A list of bibliographies of special subjects (*Chicago: The John Crerar Library, 1902, pp. 504*).—This is a classified list of subject bibliographies in the John Crerar Library, Chicago.

NOTES.

CONNECTICUT STATE STATION.—The station has introduced an innovation in the spray calendar. It has issued an attractive wall calendar, with formulas on the margin for making the common insecticides and fungicides, and leaves on the calendar pad describing briefly the common injurious insects and diseases affecting a long list of vegetables, fruits, shade trees, etc., arranged under the plant affected, together with advice as to the treatment to be given. As such a calendar is likely to be quite generally preserved, it will serve to keep the subject of spraying constantly before the farmer or orchardist, and place the necessary information where it can be readily found when needed.

CONNECTICUT STORRS STATION.—A laboratory for work in dairy bacteriology has recently been fitted up, which is thought to be the best equipped laboratory for the purpose in New England. Investigations are under way with reference to the production of soft cheese, and it is hoped that through cooperation with this Department a new industry may be introduced in that section.

IOWA COLLEGE.—According to a note in *American Agriculturist*, a new feature of the short course in stock judging at the college this year was a slaughter test, for the purpose of demonstrating the difference between different classes of animals, from the prize winner to the cow "canner." Four animals were used—the Angus steer Thistle, the winner of 4 first prizes at the International, and three others bought at the Omaha stock yards. These included an Angus heifer, a Shorthorn steer that had roughed it through the previous winter but was a "market topper" the day he was purchased for the test, and a Shorthorn cow—a typical "canner" such as are dried off and hurried to market. These were slaughtered and cut up by experts. Thistle dressed 69 per cent of meat, the Angus heifer 61.3, the steer which had roughed it 57, and the canner cow 43.2 per cent. The most radical difference in the carcasses of Thistle and the other steer was about the kidneys and loins. "While Thistle showed a fullness about the kidneys and the floor of the loin, the steer showed a great cavity here," attributed to the wasting away of these parts as a result of insufficient feed in the winter, which subsequent fattening could not correct. The demonstration proved a very interesting and instructive feature of the course.

MARYLAND COLLEGE.—The contract has been awarded for the erection of a new dormitory, for which the last legislature made an appropriation of \$25,000. The building is to be completed in the early fall.

MASSACHUSETTS COLLEGE AND STATION.—President H. H. Goodell has been granted leave of absence on account of poor health, and has gone to the island of Nassau to recuperate. The college has asked the legislature for an appropriation of a little over \$20,000 to make up the deficit caused by the shrinkage in interest on college funds, to complete the heating plant and new dining hall, and to fit up an agricultural laboratory. A new feeding-stuffs bill, giving the station increased authority in the matter of inspection, is before the State legislature. The dairy school the past winter proved a marked success and was attended by 30 students. H. A. Ballou, a graduate of the college who has been taking post-graduate work, has accepted the position of government entomologist of the British West Indies, with headquarters

at Barbados. H. M. Thomson, assistant agriculturist of the station, has resigned to take charge of a large estate in Thompson, Conn., and is succeeded by F. R. Church, a graduate of the college in 1902.

MISSOURI COLLEGE.—The publication of a series of bulletins on Agriculture in the Public Schools has been undertaken, in which it is intended to present in a systematic way for the use of teachers the principles of agriculture and horticulture. Two bulletins of the series have been published, one on *The Principles of Plant Production—The Seed*. Part 1 of this bulletin is devoted to the processes of germination and the conditions affecting germination; part 2, to the selection and testing of seeds of different kinds, and part 3, to a series of simple experiments intended to illustrate features of seed germination. The other bulletin belonging to this series is on *Plant Propagation—Some Phases of Practical Horticulture Adapted to Use in Public Schools*. This bulletin devotes a little space to directions for preparing window boxes, and then takes up methods of propagation, describing and illustrating propagation by seed, cuttings, layering, grafting, and budding. A few lines are devoted to insects and fungus diseases, and also some space to suggestions for growing kitchen vegetables.

NORTH CAROLINA COLLEGE AND STATION.—J. S. Jeffrey, of St. Catherines, Canada, has been appointed poultryman of the station and assumed charge of the work February 1. Mr. Jeffrey was educated at the Ontario Agricultural College at Guelph, and has had considerable experience in raising poultry, as well as in lecturing on the subject. A bill before the State legislature appropriating \$50,000 for the erection of an agricultural building has been favorably recommended by the joint committee on agriculture.

OKLAHOMA COLLEGE AND STATION.—R. C. Obrecht, B. S. A., a graduate of the Iowa Agricultural College, and formerly assistant at the Indiana Station, has been appointed assistant in animal husbandry in the college and station to fill the vacancy caused by the resignation of J. S. Malone.

PENNSYLVANIA STATION.—Leonard R. Cook, assistant chemist of the station, has resigned to accept a position in Cuba.

SOUTH CAROLINA STATION.—Cooperative experiments on the coast with Sea Island cotton, rice, and trucking crops are under process of organization.

TENNESSEE UNIVERSITY AND STATION.—John R. Fain, formerly farm manager, has been made assistant agriculturist in the station and assistant professor of agriculture in the university. Members of the station staff have been cooperating with the State department of agriculture in holding farmers' institutes. During the past three years some 200 addresses have been delivered to about 40,000 farmers. Chemical investigations now in progress with winter wheats from various sections of the country indicate that those grown in Tennessee show a considerably higher protein content than from other sections.

UTAH COLLEGE AND STATION.—R. W. Clark, formerly assistant agriculturist of the Alabama Station, has been elected professor of animal industry, vice F. B. Linfield, who, as previously noted, has gone to Montana. Professor Clark entered upon his duties in the college and station January 1. According to a newspaper report, the State legislature has favorably reported a bill providing for the establishment of three experiment farms, to be located by officers of the experiment station and under the control and management of that institution. The measure as introduced provided for five such farms, but the number was reduced, and a corresponding reduction made in the amount of money appropriated.

U. S. DEPARTMENT OF AGRICULTURE.—Congress has appropriated \$1,500,000 for the erection of a new building for this Department. The work of modifying the plans previously secured, so as to adapt them more definitely to the needs of the Department and to the reduced appropriation, will be taken up at once. Secretary Wilson

has designated D. E. Salmon, B. T. Galloway, and A. C. True to act as a building committee.

John Hamilton, secretary of agriculture of Pennsylvania, has been appointed farmers' institute specialist in the Office of Experiment Stations, and will enter upon his duties April 1.

AGRICULTURAL COLLEGE AND EXPERIMENT STATION EXHIBIT.—An appropriation of \$100,000 has been made by Congress to enable the United States Government Board of the Louisiana Purchase Exposition to arrange with the colleges of agriculture and mechanic arts and the agricultural experiment stations "for an exhibit of the progress of education and experimentation in agriculture, the mechanic arts, and animal husbandry."

DEPARTMENT OF AGRICULTURE IN THE TRANSVAAL.—The first number of the *Transvaal Agricultural Journal* has recently been received by this Office. The *Journal* is the organ of the newly established agricultural department at Pretoria, and this initial number tells us something of the organization, aims, and purposes of the new department. Its director is Prof. F. B. Smith, formerly of the Southeastern Agricultural College at Wye, England, who will be pleasantly remembered at a number of the experiment stations in this country, which he visited in the summer of 1900. Director Smith characterizes the department as "an administrative and advisory department that shall exercise all the functions necessary for the support, encouragement, and advancement of the rural industries of the country." Its scope will include studies and investigations upon various problems connected with agriculture, such as animal and plant diseases, injurious insects, soils, the use of fertilizers, irrigation, breeding, poultry farming, dairying, etc. A chemical laboratory and a botanical department are contemplated, and the services of veterinary surgeons, entomologists, and fruit and dairy experts are to be provided. Dr. Joseph Burt Davy, recently connected with the California University and Station, has been elected agrostologist and botanist in the new department, and will take up his duties there about the 1st of May. It is the intention of the government to establish meteorological stations throughout the country as soon as the necessary instruments are available. The department has issued a handbook for the guidance of settlers, and will publish from time to time pamphlets and circulars upon topics of importance to the farming community. The *Agricultural Journal* will be issued quarterly at the outset, and is planned to be a popular journal for disseminating practical information and recording the results of the work of the department, as well as of work in other countries which is of local interest. It will evidently be conducted on a plan similar to that of the agricultural journals in other English colonies, which have fulfilled a most useful mission.

BUREAU OF AGRICULTURE OF THE PHILIPPINE ISLANDS.—The organization of this bureau, as shown by its first annual report, is as follows: F. Lamson-Scribner, chief; E. D. Merrill, botanist and assistant agrostologist; C. W. Dorsey, soil expert; W. S. Lyon, expert in tropical agriculture; Thomas Hanley, expert in plant culture and breeding; James H. Shipley, expert in farm machinery and farm management; John W. Gilmore, expert in fibers (resigned), and G. M. Havice, superintendent of San Ramón farm, island of Mindanao. A brief account of the organization and work of the bureau is given elsewhere (p. 621).

AMERICAN TOUR OF GERMAN AGRICULTURISTS.—A party of 46 German agriculturists, landowners, and students, including representatives of the German Agricultural Society, will make a tour of this country during May and June for the purpose of studying American agriculture. The details of the tour have been largely in the hands of J. I. Schulte, of this Office, who has been designated by Secretary Wilson to act as conductor of the party. Arriving at New York about April 29, the party will proceed west via Washington, Cincinnati, Lexington (Ky.), St. Louis, Kansas

City, Ames (Iowa), Omaha, Denver, Salt Lake, and San Francisco. Several of the experiment stations will be visited en route, together with stock farms, stock yards, and packing houses, breweries and distilleries, sugar-beet farms, irrigation works about Greeley, Colo., and other features of agricultural interest. Six days will be devoted to visiting different points of agricultural and horticultural interest in California, and from four to five days to a similar itinerary in Oregon and Washington. En route east stops will be made at some typical Montana ranches, and in North Dakota a day will be spent at the experiment station and on some of the large wheat farms in that locality. The milling interests at Minneapolis will be inspected, and visits made to the Minnesota and Wisconsin experiment stations. The dairy interests will be studied in southern Wisconsin, visits to typical dairy farms, creameries, and cheese factories being contemplated. Arriving at Chicago via Milwaukee, the party will spend several days in looking over the live-stock and packing interests, the manufacture of agricultural machinery, and other industries. The route east will be through Michigan and New York, to look over the fruit industry and other agricultural features of these States and spend a day at Cornell University. At Boston the truck gardening carried on in the vicinity, the park system of the city, and a horse farm in a neighboring town will be viewed, and on the way back to New York there will be opportunity to see the culture of tobacco in the Connecticut Valley, and especially the method of growing this crop under shade. The party will sail for Germany June 30.

PRIZE COMPETITION.—The Association of Thomas Phosphate Works (*Verein der Thomasphosphatfabriken*), of Berlin, has offered a series of prizes for investigations on the increase of fertility in soils by the action of bacteria and other micro-organisms, under the influence of mineral fertilizers, with special reference to manuring with basic slag. The announcement refers to the progress which has been made in studying the relation of bacteria to the assimilation of nitrogen, nitrification, etc., and suggests that bacteria have an important influence on the chemical-physical condition of the soil by transforming the fertilizing ingredients of the soil into assimilable form, by improving the physical properties of the soil, etc. To encourage investigations on this subject, which are thought to be of great practical importance to agriculture, the association offers prizes amounting to 40,000 marks (nearly \$10,000), as follows: First prize, 15,000 marks (about \$3,600); second prize, 10,000 marks (about \$2,400); third, 6,000 marks (about \$1,450); fourth, 4,000 marks (about \$960). The remaining 5,000 marks are at the disposal of the judges, to be awarded for valuable scientific and practical results in the same direction. The competition is open to all, without regard to nationality. The papers, written in German, are to be sent to the association (Hafenplatz 4, Berlin S. W.) not later than February 1, 1906. The board of judges consists of Dr. L. Hiltner, of Munich; Prof. Alfred Koch, of Göttingen; Professor Remy, of Berlin; Prof. A. Stutzer, of Königsberg, and Director H. Wilfarth, of Bernburg.

MISCELLANEOUS.—A brief review of the proceedings of the international weather-shooting congress, held at Gratz in July, 1902, is given in a recent number of *Nature*. The director of the Vienna Central Bureau of Meteorology and Terrestrial Magnetism, Professor Penner, was the general reporter of the congress, and the proceedings appear as a publication of his bureau. In summarizing the results he states that the effect of weather shooting, based on expert evidence, appears not only doubtful but indeed improbable, when all circumstances and different weights of opinions are considered. The opinion seemed to prevail, however, that the firing should not be given up, but continued until it is proved that it has not the desired effect.

The government of German East Africa has recently established a biological agricultural institute at Amani, with Prof. A. Zimmermann as director and botanist. The staff includes in addition to the director a chemist, zoologist, secretary, and three

planters. A laboratory and dwelling to cost about \$16,000 are building. The lines of work to be undertaken include the investigation of the food requirements and habits of growth of tropical cultivated plants, study of insect pests and fungus diseases and methods of eradicating them, analysis of soils and fertilizers, examination of animal and vegetable products intended for export or home consumption, and a study of the flora and fauna of German East Africa.

We note from *Science* that Sir William Macdonald, of Montreal, has donated a further sum of \$4,500 to the Macdonald Institute at the Ontario Agricultural College, Guelph, to complete the furnishing. This makes a total of \$175,000 given by Sir William to this institute.

C. Martin, director of the dairy school at Mamirolle, France, has been retired at his own request and is succeeded by M. Houdet.

The *Biochemisches Centralblatt*, an abstract journal for biochemistry, covering the field bordering on medicine and chemistry, is one of the latest of the new scientific serials. Judging from the numbers issued thus far, it will review papers on the physiology of human nutrition, hygiene, sanitation, milk and water supply, ferments, toxins, parasites, immunization, etc. It will be issued semimonthly.

In a statement of the needs of the University of Oxford, circulated by the vice-chancellor, better endowment was asked, among other things, for the Sibthorpe professorship of rural economy (now suspended).

A laboratory has been opened in the gardens of the Royal Botanic Society at Regent's Park, London, in which classes for instruction in botany and "horticultural chemistry" are held three days a week. The laboratory has been erected and equipped under the auspices of the technical education board.

A committee has been formed in Germany to provide for the erection of a memorial at Munich to Prof. Max von Pettenkofer, in recognition of his important contributions to sanitation and hygiene.

The German Government has appropriated \$15,000 for research for the study of the relation between tuberculosis in man and cattle.

EXPERIMENT STATION RECORD.

VOL. XIV

APRIL, 1903.

No. 8.

The total appropriations made for the U. S. Department of Agriculture by the two sessions of the Fifty-seventh Congress aggregate \$12,005,133.80. Of this amount \$10,687,120 was appropriated for current expenses in the usual way, \$1,000,000 was a special appropriation for the purpose of eradicating the foot-and-mouth disease in New England, \$250,000 was for the purpose of inaugurating authorized work on the new agricultural building, and \$68,013.80 was to meet certain deficiencies. The net increase for the entire Department over the appropriations made by the Fifty-sixth Congress was \$2,228,753.80.

The appropriation provided by the recent session of Congress for the next fiscal year amounts to \$5,978,100. Including an emergency appropriation of half a million, this is an increase of \$769,140 over the appropriation for the current year. Nearly every bureau and division receives additional funds, but the wording of the appropriation act mentions very few new undertakings. The increases are for the most part to enable an extension of the work of the Department along its present lines, rather than to take up new special features. The largest increases are for the Bureaus of Animal Industry, Plant Industry, Forestry, and Soils.

The Bureau of Animal Industry receives an increase of \$100,000 for the extension of its meat and other inspection work, making a total of \$1,287,380; and an emergency appropriation of \$500,000 is placed at the disposal of the Secretary of Agriculture to stamp out the foot-and-mouth disease, which has recently raged in several of the New England States, and other contagious diseases of animals which may appear.

The Bureau of Plant Industry receives a total increase of \$42,200 for its work in vegetable pathology and physiology, botanical investigations, studies of the pomaceous fruits and their handling, and the experiments with grasses and forage plants. These increases will enable more extensive work in plant breeding, especially to secure crops resistant to alkali, disease-resistant beets, the hardy orange, and the improvement of Indian corn; a continuation on a larger scale of the field trials with nitrogen-fixing organisms in growing leguminous plants, and a larger amount of attention to plant diseases, notably the Texas root rot of cotton and the California vine disease. The increase

for botanical investigations will be used for developing the studies of poisonous plants, particularly on the western ranges. The fund for the purchase of seeds for Congressional distribution is increased by \$20,000, making the amount \$290,000. An additional \$10,000 is allowed to be expended out of this fund for the introduction of seeds and plants from foreign countries, which raises the fund for that purpose to \$30,000. The total for the Bureau is \$674,930.

The amount for the Bureau of Forestry is increased to \$350,000, which is \$58,140 more than the current appropriation, and will enable an extension of the forestry and timber investigations and the preparation of working plans for owners of woodlands. The Bureau of Soils receives \$212,480 for its soil survey and tobacco work, \$42,800 more than the present year.

The scientific staff of the Weather Bureau is increased somewhat, an assistant chief being added, and the Bureau is authorized to erect five new observatories, and to establish cable communication between Block Island and Narragansett Pier, with terminal buildings and equipment at each place. Its total appropriation amounts to \$1,248,520.

The appropriations for the experiment stations in Hawaii and Porto Rico are increased to \$15,000, making them uniform with the stations in other States and Territories; and \$5,000 is appropriated for taking up the farmers' institute work with a view to assisting the organizations in the different States and Territories and making them more effective means for the dissemination of the results obtained at the Department and at the experiment stations. As previously mentioned, John Hamilton, of Pennsylvania, has been appointed farmers' institute specialist in the Office of Experiment Stations. The increases, together with the appropriations for the Office proper and for the irrigation and nutrition investigations in its charge, bring the total up to \$895,000.

The Division of Statistics is raised to the grade of a bureau, and given an increased appropriation of \$15,500 for general maintenance, making a total of \$156,660.

Other items carried by the act are \$85,300 for the Bureau of Chemistry, an increase of \$11,600; \$77,450 for the Division of Entomology, an increase of \$10,000; \$51,850 for the Division of Biological Survey, an increase of \$6,000; \$229,320 for the Division of Publications, which does not include the funds for printing the Department publications, except \$105,000 for Farmers' Bulletins; \$16,000 for the Division of Foreign Markets; \$35,000 for Public Road Inquiries, an increase of \$5,000; \$20,000 for the Library; and \$138,210 for administrative, contingent, and general expenses.

The Department's allotment out of the general printing fund is \$185,000, an increase of \$10,000, and \$300,000 is provided annually for printing and binding a half million copies of the Yearbook. Adding

to this the cost of the regular and special reports, which are printed by order of Congress, brings the amount for printing the Department publications up to approximately three-quarters of a million dollars.

In the last fiscal year the Department issued 757 publications, in an aggregate edition of 10,586,580 copies, some six million of which were Farmers' Bulletins. The cost of printing the publications is now equivalent to less than 20 per cent of the total appropriation for the Department, whereas during the first twenty years of its existence the cost of printing was more than half of the whole expenditure; that is, the cost of distribution of information considerably exceeded the amount expended in its acquisition. Although the number and cost of publications increases steadily every year and the output is now enormous, the productive power of the Department has increased in far greater proportion, and where one thousand dollars is now spent for the dissemination of information, five thousand is expended in the acquisition of knowledge.

The increase in appropriation for the Bureau of Soils provided for next year will be used in extending the soil survey and in the tobacco work. Surveys will be made this season in thirty-two States, instead of twenty-six as the past season. Twenty parties are now preparing to go into the field for the season's work, which will be taken up, as a rule, April 1. The assignments for these parties cover three periods in each case, i. e., April 1 to July 1, July 1 to October 1, and October 1 to January 1. A change of location is frequently indicated for each period, and this is usually made in conformity with the advancing season. For example, one field party will survey the tobacco soils between Viroqua and Sparta, Wis., during the first quarter, then proceed to Davidson County, Tenn., for the second quarter, and spend the last quarter in Lauderdale County, Ala. Another party will work in the Connecticut Valley during the spring and summer, extending the survey of 1899 up the northern boundary of Massachusetts, and during the last quarter of the year will survey the southeastern portion of the Harpers Ferry district in Virginia. A third party will spend the first quarter near Provo, Utah, the second in the Milk River district of Montana, and the last in a survey of the area between The Needles, California, and Yuma, Ariz., in which it will be joined by three other field parties.

In several cases the entire season will be spent in the same State or region. This is the case with the survey of Long Island, and of the Santa Clara and Sacramento valleys in California. Parties will spend the whole season in Illinois and in Louisiana making surveys in several localities of these States, with the aid and cooperation of the experiment stations.

In all, over fifty counties and localities are mentioned in the assignments for the year, which will be found on p. 825. This

indicates the wide distribution of the work as contemplated in the season's campaign.

The tobacco investigations will be confined principally to experiments with the Cuban filler tobacco in Alabama, the central part of South Carolina, and Eastern Texas, where soils have been located similar to those on which it is successfully grown. Five parties will be sent into the field this season. One of these will be assigned to the general charge of the work in Connecticut, with headquarters at Hartford, and another will operate in Ohio. The headquarters for the Cuban tobacco work will be in eastern Texas, where a party of six will be located. Smaller parties will be in charge of the work in Perry County, Ala., and Darlington County, S. C. The work will be largely cooperative, and will be carried on with the assistance of local growers.

The Department is to have a model school garden on its grounds the coming season, as a result of the interest which has been aroused in the normal school of the District.

The horticulturist, Prof. L. C. Corbett, of the Bureau of Plant Industry, gave a course of lectures at the school on plant propagation and garden work in the winter of 1901-2, and last season the Department furnished seeds and plants for about forty school gardens in the District. During the past winter nearly one hundred young women from the normal school have had practical instruction in plant propagation at the Department, a small greenhouse being set aside for the purpose. The pupils did all of the work connected with the preparation of the soil, potting the plants, and managing the house, under the immediate direction of the instructor in botany in the school.

A small piece of land on the Department grounds has been allotted for the school garden, which will be conducted under the direction of several of the pupils who have had instruction the past winter. This tract will be divided up into miniature vegetable and flower gardens, to be worked by pupils from a school near by, small prizes being provided by the instructor in botany in the normal school.

Collections of vegetable and flower seeds for gardens have been sent out to several hundred schools which have requested them, and a large number of calls have been received from village improvement societies and similar organizations. The latter it has been impossible to meet, unfortunately, out of the quota of seeds placed at the disposal of the Secretary.

These facts are further indication of the wide interest which is felt or can be aroused in these matters by a little effort and encouragement, especially when the encouragement comes in the practical form of providing the wherewithal and the directions for making a beginning.

NEW BUILDINGS AT THE NEW HAMPSHIRE AND MISSOURI AGRICULTURAL COLLEGES.

One of the most evident signs of the better financial support which is being accorded our agricultural colleges is the increasing number of new buildings provided for their work and that of the experiment stations. In the past two years more than twenty-five new buildings for class-room instruction and laboratories for the agricultural colleges and the experiment stations have been provided by State appropriation.

In several cases these have been large, imposing buildings, designed to house the principal departments of the agricultural college, and comparing in size and general character with any on the college campus. In other cases they have been intended for a group of related departments, or for some single line of instruction and research. But they have uniformly been of a style of construction which gives character and an air of permanency to the departments which they represent, and is in marked contrast to the buildings which public sentiment made possible a few years ago.

This improvement in equipment has come as a response to popular sentiment and the real needs of the agricultural work, and can not be said to be an anticipation of the needs of that department of instruction. In this respect the result is encouraging and inspiring to the friends of agricultural education.

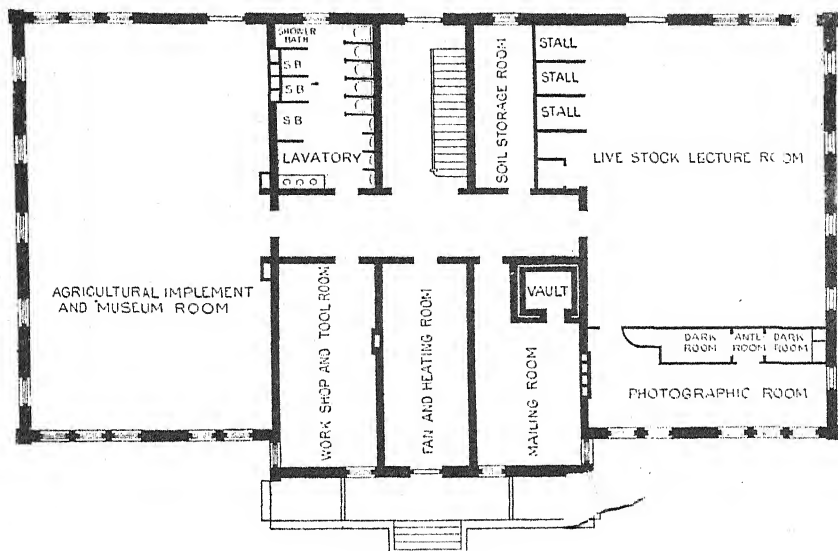

The new agricultural building at the New Hampshire College of Agriculture and Mechanic Arts, known as Morrill Hall (Pl. I, fig. 1), is intended to house the departments of agriculture, including agronomy and animal industry, horticulture and forestry, and botany. These departments have heretofore occupied a building jointly with the experiment station.

The State legislature in 1901 appropriated \$30,000 for the building, which was begun in May, 1902. The college assumed the cost of preparing the foundations, and the contract was made for the building with the attic unfinished. The contractor's work is now nearly completed and the building will be occupied as soon as it can be equipped.

The dimensions on the ground are 58 by 110 feet, with a projection in front 14 by 44 feet, which provides for entrances. The building is constructed of brick with dressed granite trimmings and a slate roof. All partitions are of brick, and below the attic wood is limited to floors, casings for doors and windows, baseboards, and chair rails.

A feature of the building is the mortar for the outside courses of brick, which was prepared from selected lime containing the least

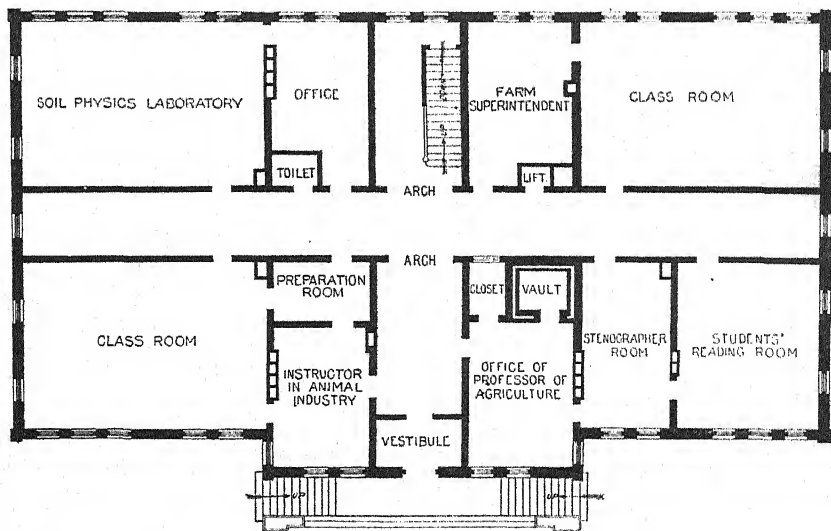

possible percentage of magnesia, in order to prevent the white coating which so often disfigures brick buildings.

BASEMENT PLAN

Fig. 1.—New Hampshire Agricultural Building.

In the basement of the building (fig. 1) is an implement museum, 32 by 54 feet, and a live-stock amphitheater, 32 by 43 feet; also photographic room, lavatory, and storerooms. The walls in the basement are whitened, making the rooms light and cheerful.

PLAN OF FIRST FLOOR

Fig. 2.—New Hampshire Agricultural Building.

FIG. 1.—AGRICULTURAL BUILDING, NEW HAMPSHIRE AGRICULTURAL COLLEGE.

FIG. 2.—DAIRY BUILDING, MISSOURI AGRICULTURAL COLLEGE.

The first floor (fig. 2) contains a soil laboratory, 22 by 36 feet, class rooms for animal husbandry and agronomy, each 22 by 32 feet, offices, and reading room.

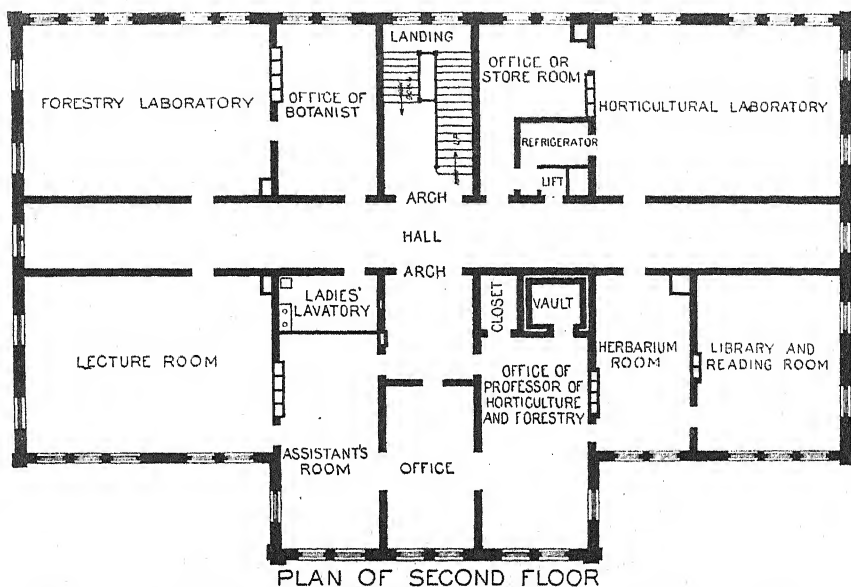

FIG. 3.—New Hampshire Agricultural Building.

The second floor (fig. 3) contains laboratories for forestry and horticulture, each 22 by 36 feet, class room 22 by 32 feet, offices, reading room, and herbarium. The walls of all rooms on the first and second floors are tinted in subdued colors.

When finished, the attic will contain a room 29 by 47 feet for the classes in drawing, which will be lighted from one end and skylights overhead. A smaller room, 29 by 34 feet, will provide accommodations for meetings of the students' agricultural society.

The Missouri State legislature in 1901 appropriated \$40,000 for a dairy and live-stock building. It was subsequently decided, however, to erect two separate buildings instead of combining all in one.

The dairy building (Pl. I, fig. 2) is 45 by 150 feet, and two stories in height, with cheese-curing rooms in the basement. It is built of crystalline limestone, with a slate roof. It contains on the first floor (fig. 4) all of the operating rooms, viz, a creamery room 40 by 51 feet in the clear, which will accommodate 7 power separators, the necessary ripening vats, pasteurizers, churns, butter workers, printers, etc.; a cheese room, at present 40 by 42 feet, and a farm dairy room 22 by 40 feet. The partition between the cheese room and the farm dairy room is temporary and may be removed at any time without defacing the building or in any way interfering with the stability of the structure, so as to

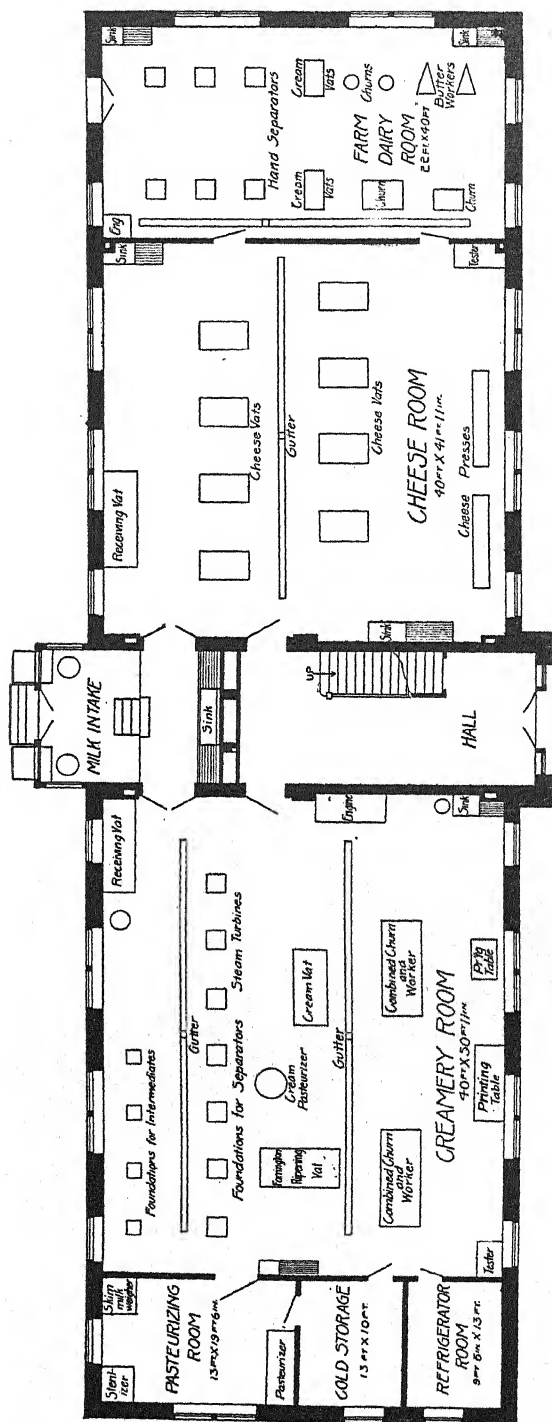

FIG. 4.—Missouri dairy building—plan of first floor

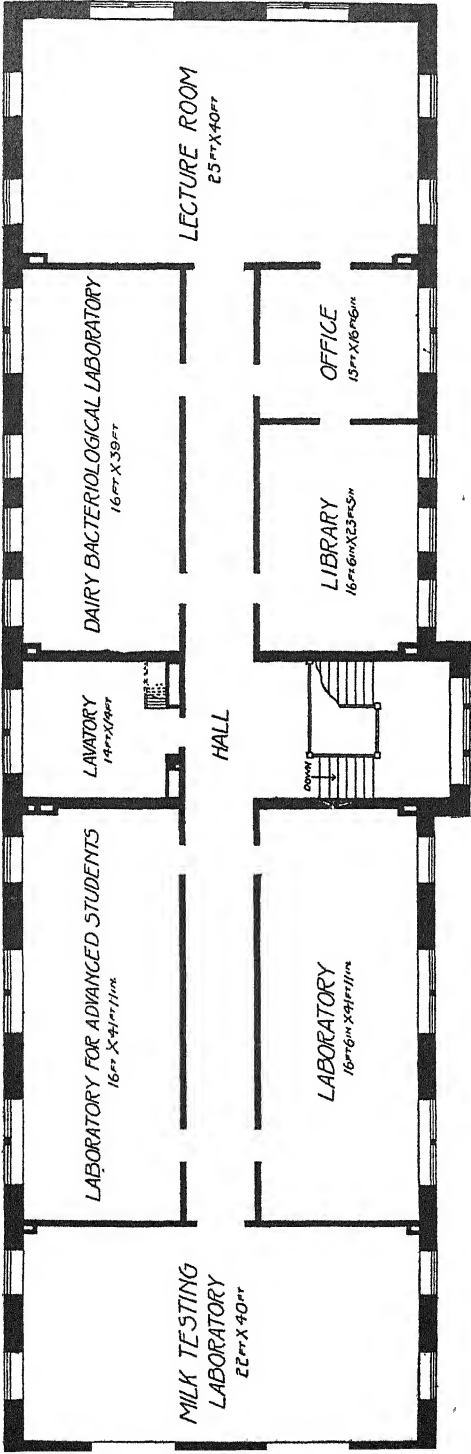

FIG. 5.—Missouri dairy building—plan of second floor.

give a cheese room 40 by 64 feet, if the work in this line should expand enough to require it. On the same floor is a pasteurizing room, 13 by 19½ feet, for instruction in bottling and the handling of milk for city trade; and two cold-storage chambers where different temperatures

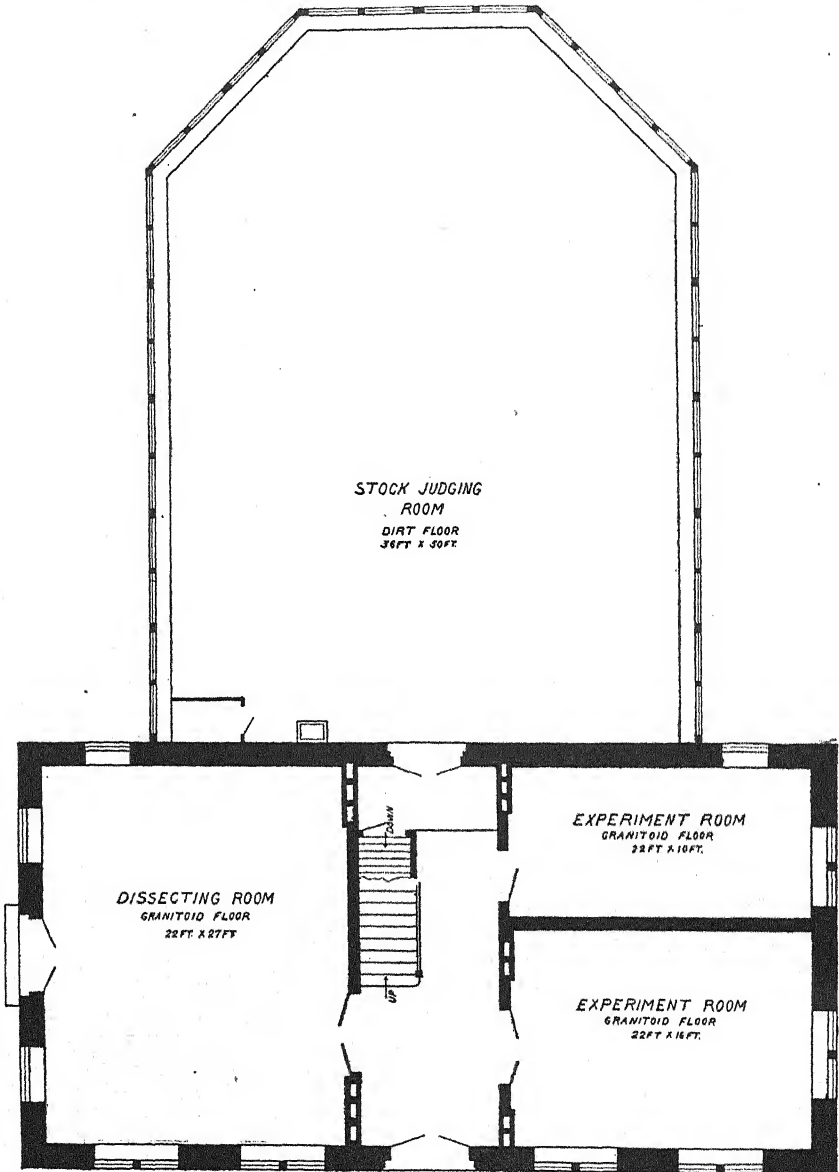

FIG. 6.—Missouri live-stock building—plan of first floor.

may be maintained for the keeping of butter and the curing of cheese. The milk is delivered at the center of the building in the rear, flows by gravity from the weigh can to the receiving vat in the creamery

room or the cheese room, as may be desired, and from that point is pumped to the separators or the cheese vats.

The second floor (fig. 5) contains four laboratories, a lecture room which will accommodate 100 students, an office for the professor in charge, and a library and reading room where the dairy library of the university will be kept. All the laboratories have north and east light with the exception of one milk-testing room.

The building is heated by the indirect method from steam coils in the basement, with a fan to force the warm air through the building and insure complete ventilation.

The live-stock building is designed to afford a class room, laboratories, and breeding room, and a judging pavilion for instruction in live stock. The veterinary department will use the laboratories and a part of the animal rooms temporarily, but the legislature has made an appropriation of \$15,000 for a hospital for the veterinary department,

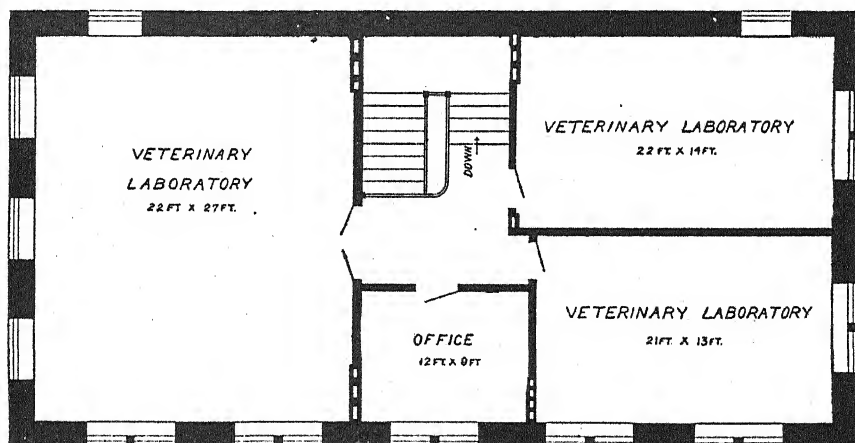

FIG. 7.—Missouri live-stock building—plan of second floor.

and a bill is now pending for \$50,000 for veterinary laboratories, so that there is every probability that the entire building can be turned over to the animal husbandry department at an early date.

The first floor (fig. 6) contains at present a dissecting room 22 by 27 feet, and two experimental animal rooms, one 22 by 16 and one 22 by 10 feet, and a judging pavilion 36 by 50 feet. The judging pavilion will accommodate a class of forty students with ten animals.

The second floor (fig. 7) contains three veterinary laboratories—one 22 by 27 feet, another 21 by 13 feet, and another 22 by 14 feet, and an office. These rooms will ultimately be used for class rooms and laboratories for animal husbandry, when they are vacated by the veterinary department.

This is a stone structure covered with slate and heated by the indirect method, like the dairy building.

RECENT WORK IN AGRICULTURAL SCIENCE

CHEMISTRY.

A new gravimetric and gasometric modification of the molybdic method for the determination of phosphoric acid and magnesia, E. RIEGLER (*Ztschr. Analyt. Chem.*, 41 (1902), No. 11, pp. 675-686, fig. 1).—The gravimetric method for phosphoric acid rests upon the fact that barium chlorid produces in an ammoniacal solution of ammonium phosphomolybdate a precipitate, perfectly insoluble in water, containing 1.75 per cent of phosphoric anhydrid and 45.5 per cent of barium, corresponding to the formula $\text{Ba}_{27}(\text{MoO}_4)_{24}\text{P}_2\text{O}_5 \cdot 24\text{H}_2\text{O}$. The weight of the precipitate, dried at 100° C. multiplied by 0.0175, gives the weight of phosphoric anhydrid. In the gasometric method an excess of barium chlorid is added and this excess determined by conversion into iodate by addition of hydroiodic acid, the iodate being decomposed by addition of hydrazin sulphate with evolution of nitrogen, which is measured and furnishes a basis for calculating the excess of barium chlorid. This subtracted from the total amount of chlorid used gives the amount required for precipitation. The 2 methods may be used on the same portion of the original solution and thus serve as a check on each other. They were found to give very concordant results in a number of tests. A table containing factors for correcting results for different barometric pressures and temperatures is given and the apparatus used is described. For determination of magnesia this substance is first precipitated as ammonium-magnesium phosphate, which is dissolved in nitric acid and precipitated as ammonium phosphomolybdate, the further treatment being the same as that just described.

Determination of phosphoric acid in fertilizers, A. G. WOODMAN (*Engineer. and Mining Jour.*, 74 (1902), p. 781; *abs. in Chem. Ztg.*, 27 (1903), No. 3, *Reper.*, p. 5).—In the method described 2 gm. of substance is heated in a covered beaker with 10 cc. each of strong hydrochloric acid and water and 1 to 2 gm. of sodium chlorate until the chlorin is driven off. The volume is made to 250 cc., and to 25 cc. of this solution in an Erlenmeyer flask 15 cc. of ammonia (0.9 sp. gr.) is added and neutralized with strong nitric acid. The solution is heated to 65° C., and 25 to 75 cc. of ammonium molybdate is added, shaking vigorously. The precipitate, which settles quickly, is collected on a filter and washed. The filter and contents are returned to the Erlenmeyer flask and standard potash solution added until the precipitate is almost dissolved. Phenolphthalein is added and the addition of the potash solution is continued until the color remains for 1 minute. If the potash solution used consists of 323.81 cc. of normal solution diluted to 1 liter, each cubic centimeter corresponds to 1 mg. of phosphoric acid.

The valuation of Thomas slag, B. SJOLLEMA (*Jour. Landw.*, 50 (1902), No. 4, pp. 367-370).—Phosphoric acid was determined in a sample of Thomas slag by treatment with (1) strong nitric acid, (2) Wagner's method, and (3) repeated extraction with 2 per cent citric acid. In the latter case the slag was (1) shaken in a flask with successive portions of 150 cc. of acid, allowed to stand some hours, and the solution filtered, and (2) mixed with sand, placed in a tube, and washed with the acid. Two

liters of citric acid was used in each case. The repeated extractions gave results agreeing quite closely with those furnished by the mineral acid extraction, but considerably higher than those given by the Wagner method.

On the determination of citric-acid soluble phosphoric acid, M. PASSON (*Chem. Ztg.*, 27 (1903), No. 4, p. 33).—The author describes a slight modification of the oxidation method of Passon and Mach.^a

Transformation of pyrophosphoric acid into orthophosphoric acid, H. GRIAN (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 22, pp. 961-963).

On the determination of calcium in the form of oxalate, V. PAGUIREF (*Zhur. Russ. Fiz. Khim. Obsch.*, 34 (1902), No. 2, pp. 195-199; *abs. in Bul. Soc. Chim. Paris*, 3. ser., 30 (1903), No. 1, p. 95).—In order to obtain a precipitate which will not run through the filter the author adds to a neutral solution of calcium salt in the cold an excess of oxalic acid, stirring the solution at the same time; then ammonia, drop by drop, until a slightly alkaline reaction is obtained. The solution is heated and stirred continuously to drive off the excess of ammonia. The precipitate thus obtained is of the same composition as that obtained by the ordinary method, but is more compact, settles completely in less than 4 hours, and does not pass through the filter.

A rapid gravimetric method of estimating lime, F. B. GUTHRIE and C. R. BAKER (*Agr. Gaz. New South Wales*, 13 (1902), No. 12, pp. 1215, 1216).—Lime is precipitated as oxalate and reduced to oxid by ignition in a platinum crucible with ammonium nitrate. The crucible is placed in a slanting position and partly covered with the lid. Heat (from a Bunsen burner) is applied to the lid until danger of spurring is passed, when the crucible is heated directly for about 5 minutes.

On the determination of free lime in Thomas slag, M. BISCHOFF (*Chem. Ztg.*, 27 (1903), No. 4, p. 33).—Comparative tests of Scheibler's sugar-solution method and extraction with water are reported. The first gave much higher results than the second, but it was found that on boiling the sugar-solution extract a precipitate of calcium carbonate was obtained, showing that the sugar-solution extracts carbonate as well as free lime. For this reason the extraction with water is considered the more reliable method.

Lime determinations by means of Passon's apparatus, M. PASSON (*Deut. Landw. Presse*, 30 (1903), No. 4, pp. 26, 27).—It is stated that the determinations by means of the apparatus are too high when large amounts of sand, clay, etc., are present. A table of corrections to be used is given.

Passon's lime test, T. PFEIFFER (*Deut. Landw. Presse*, 30 (1903), No. 6, p. 44).—Reports results of tests which indicate the unreliability of the method, even with corrections applied as suggested by the author. (See above.)

On the determination of perchlorates, M. HÖNIG (*Chem. Ztg.*, 27 (1903), No. 4, pp. 32, 33).—The author fuses the salt containing perchlorate with iron filings in a nickel crucible. This reduces the perchlorate to chlorid, which is determined gravimetrically.

A titration method of determining hardness of water by means of aqueous soap solutions, A. GAWALOWSKI (*Ztschr. Analyt. Chem.*, 41 (1902), No. 12, pp. 748-752, figs. 2).—Water solutions (1 cc. corresponding to 0.0012 gm. CaO) of neutral sodium oleate or of commercial soap made of soda and coconut oil are recommended. The method of titration is practically the same as that usually employed, except that green glass flasks marked at 25, 50, 75, and 100 cc., for use with waters of different degrees of hardness, are employed, and a small amount of carmine tincture is added to assist in defining more clearly the point of saturation.

A volumetric method for the determination of tannin and the analysis of tanning materials and extracts, A. THOMPSON (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 17, pp. 689-691).

^a *Ztschr. Angew. Chem.*, 1896, p. 129

A method for the determination of glycerin in wine, A. TRILLAT (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 21, pp. 903-905).

On albuminoid substance extracted from maize seed, E. DONARD and H. LABBÉ (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 18, pp. 744-746).—The method of preparation and the chemical properties of a maize proteid, "mazaine," are here described, and an elementary analysis reported. The author states that corn contains 4 to 4.5 per cent of this proteid.

On musculamine, a new derivative from muscles, A. ETARD and A. VILA (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 17, pp. 698-700).—A brief note describing a base prepared from muscular tissue for which the name "musculamine" is proposed.

Experiments with Wollny's refractometer for milk analysis, S. HALS (*Aarsbr. Offent. Foranstalt. Landbr. Fremme*, 1901, pp. 402-409).—The Wollny refractometer was compared with the Adams method for the analysis of fresh milk, gravity and separator skim milk, watered milk, and adulterated milk of various kinds, in a study of the applicability of the refractometer in milk control stations. It was found that the results with the Wollny refractometer were more accurate than those obtained with the Gerber butyrometric method, and as a rule differed from the gravimetric results by less than 0.1 per cent. Owing to the great care required in the manipulation of the method, the many different steps, the expense of the reagents, etc., the refractometer is not recommended in preference to the Gerber method in milk analysis where a large number of samples are to be tested daily, as, for example, at milk control stations.—F. W. WOLL.

Proceedings of the first annual meeting of the Association of German Food Chemists (*Ztschr. Untersuch. Nahr. u. Genussm.*, 5 (1902), No. 21, pp. 993-1111).—Among the subjects considered at the meeting, which was held at Eisenach in August, 1902, were the examination of Italian pastes and similar materials, the detection of margarin in butter, the detection of fluorin in plants, quantitative examination of aqueous solutions by the immersion refractometer, the quantity and determination of boric acid in plants, the direct gravimetric determination of boric acid in foods, lactic acid in wine, the lecithin content of fats, weed seeds, especially cockle, in meal, and changes in beeswax due to bleaching with chemicals.

Synopsis for use in analysis and examination of preserved foods, etc., C. MANGET (*Tableaux synoptiques pour l'analyse des conserves alimentaires*. Paris: J. B. Baillière & Sons, 1902, pp. 88, figs. 13, dqms. 2).—Tabular statements are given for guidance in the analysis and examination of preserved meats, lard, milk, etc.

Report of the Chemical Control Station, Trondhjem, Norway, 1901, T. SOLBERG (*Aarsbr. Offent. Foranstalt. Landbr. Fremme*, 1901, pp. 220-254).—The total number of samples examined at the station during the year was 873, including feeding stuffs, fertilizers, soils, and foods. The results of the analyses are given and discussed. Accounts are also embodied in the report of 7 different series of fertilizer experiments on farms located in the vicinity of Trondhjem.—F. W. WOLL.

Annual report of the progress in agricultural chemistry, 1901, A. HILGER, T. DIETRICH, ET AL. (*Jahresber. Agr. Chem.*, 3. ser., 4 (1901), pp. XXXVIII + 613).—This contains abstracts of the more important articles in agricultural chemistry published in 1901 and titles of articles of less importance. The subjects are classified under plant production, animal production, agricultural technology, and methods of investigation.

Annual report of the progress in chemistry and related parts of other sciences, 1894, G. BODLÄNDER, W. KERP, G. MINUNNI, ET AL. (*Jahresber. Fortschr. Chem.*, 1894, Nos. 1-9, pp. 2848).—This volume, published in 1902, contains abstracts of literature of chemistry and related subjects, with classified table of contents and author and subject indexes.

BOTANY.

The effect of sunshine on plants, N. PASSERINI (*Bul. Soc. Bot. Ital.*, 1902, pp. 13-24; *abs. in Jour. Roy. Micros. Soc. [London]*, 1902, No. 5, p. 574).—The results of growing 13 different species of plants in direct sunlight and in diffused light are shown. By analyses the author determined the relative percentages of water, organic matter, and ash of the 2 sets of plants. The highest gain was found in a gourd where the plant grown in sunshine was 27 times heavier than the shaded plant. Next to this in gains were barley and maize, the difference in each case being about 9 times as great for the plants grown in the sunlight as in the shade. The greatest gain in organic substance was shown by rape, barley, and pimpinell. The conclusions drawn by the author are that in every case the plant exposed to direct sunlight is heavier than the shaded plant, and that the failure of direct radiation limits the growth of the plant and retards its vegetative phases, especially the inflorescence and the complete development of the fruit. Plants grown in direct sunshine are much greener than the shaded plants, and the shaded plants have a larger proportion of water and less solid substance. The higher percentage of solids in the sun-grown plants is chiefly due to the organic matter, the difference in the proportion of mineral matter being less noticeable.

Influence of X-rays on plants, H. SECKT (*Ber. Deut. Bot. Gesell.*, 20 (1902), No. 2, pp. 87-93; *abs. in Jour. Roy. Micros. Soc. [London]*, 1902, No. 4, p. 455).—The author found that the exposure to X-rays distinctly favored the streaming movement of protoplasm and the leaf movements of *Mimosa* and *Oxalis*. After from 15 to 45 minutes' exposure to these rays movements which before had been very slow became quite rapid. When the tube of the apparatus experimented with was placed too close to the object a greater or less tendency to plasmolysis was observed. This the author attributes to the harmful action of other electric waves.

Electrical phenomena in plants, A. TOMPA (*Bot. Centrbl., Beihefte*, 12 (1902), pp. 99-136, figs. 3; *abs. in Jour. Roy. Micros. Soc. [London]*, 1902, No. 5, p. 574).—There was found to be no essential difference of intensity in manifestation of electric polarization in living and dead seeds. The polarization currents in both dead and living seeds may reach considerable intensity but are of small tension. The amount, intensity, and the direction of the current vary according to variations in the internal resistance of the seed. It is claimed that the question of living seeds may be determined by what are termed lesion currents. A lesion current whose potential exceeds 0.005 volt may be considered as a criterion of life in a seed.

Electric response in plants under mechanical stimulus, J. C. BOSE (*Jour. Linn. Soc. [London]*, Bot., 35 (1902), pp. 275-304, figs. 25; *abs. in Jour. Roy. Micros. Soc. [London]*, 1902, No. 5, pp. 574, 575).—The object of the author's experiments was to prove that plants and their different organs respond to electric stimuli in the same way that animal tissue responds, indicating that vital phenomena are identical in the animal and plant kingdoms. The responses are held to be physiological, since whatever influences the physiological activity of the plant also tends to increase or diminish the electric response. The author emphasizes the importance of this unity between plants and animals; and owing to the simpler conditions which obtain in plant life, the electro-physiological investigations in plants may be found to throw much light on this subject.

Concerning the respiration of injured leaves, N. DOROFIEJEW (*Ber. Deut. Bot. Gesell.*, 20 (1902), No. 7, pp. 396-402).—By separating leaves from the plants bearing them and placing them under various conditions the author studied the effect of such separation and injury upon the respiration of the leaves. It was found that the carbohydrates present in the leaves influence their respiration to an important degree. If the carbohydrates are abundant there is but a slight increase in the respiration due to the wounding, while if the amount is small the respiration is greatly accelerated. This was found to be true both for green and etiolated plants.

Influence of irritation on the growth of unicellular plants, J. TRZEBINSKI (*Bul. Internat. Acad. Sci. Cracovie, 1902, pp. 112-130; abs. in Jour. Roy. Micros. Soc. [London], 1902, No. 4, p. 471*).—A series of observations was made on the growth of *Phycomyces nitens* under the influence of various irritants. Mechanical injury was found to lower the turgescence and retard the growth of the hyphae. Even very slight injuries were found to act to the detriment of the plant. The irritation of the sporangium by means of slender glass rods or similar agents caused an increase in the growth of the stalk. The vapor of ether induced a more rapid growth when present in an open vessel but if too condensed the growth was entirely stopped. The experiments are held to show a marked similarity between the higher and lower plants in response to various stimuli.

The permeability of protoplasm, VAN RYSELBERGHE (*Rec. Inst. Bot. Univ. Bruxelles, 5 (1902), pp. 209-249, pls. 6; abs. in Jour. Roy. Micros. Soc. [London], 1902, No. 4, p. 442*).—Observations are reported on the influence of temperature on the permeability of living protoplasm. The principal observations were on the contraction and expansion of living elder pith and of the epidermal cells of *Tradescantia*. It was found that the permeability of the protoplasm increased with the rise of temperature. At 30° C. the protoplasm was 8 times more permeable than at 0°. The permeability was found to be greatly reduced but not completely checked at 0° C., and this applied not only to the passage of water but also of substances held in solution. The passage of water was found to take place under greatly reduced osmotic pressures, and it is thought probable that there is no minimum force of filtration below which no passage of water takes place. It was further found that when the cell sap of the cell was isotonic with a certain solution at a given temperature it remained isotonic with the same solution at all temperatures, providing changes in the cell sap had not taken place by adaptation.

Predisposition and immunity in plants, H. MARSHALL WARD (*Proc. Camb. Phil. Soc., 11 (1902), pp. 307-328; abs. in Jour. Roy. Micros. Soc. [London], 1902, No. 4, p. 473*).—A discussion is given of the predisposition and immunity of certain plants to disease, based upon the author's investigations on the culture of rusts on brome grasses. His studies were confined to inoculation experiments with the uredospores of *Puccinia dispersa*, and the results obtained led to the conclusion that the source from which the spores are taken and the specific characteristics of the grass inoculated must both be taken into account if infections were successful. Certain species of grasses were readily infected by spores taken from individuals of the same species, but were immune to those of other brome grasses in an increasing degree as the species was further removed in its systematic relationship. It was found to be very difficult to inoculate plants from one specific group to another, and although the various characters of the plants were studied the conclusion was reached that the capacity for infection is due to some biological distinction and is wholly independent of the anatomical structure.

The origin of variegated varieties of plants, E. LAURENT (*Bul. Soc. Roy. Bot. Belg., 39 (1900), II, pp. 6-9*).—According to the author, variegation is of 2 forms—(1) that which is produced from seeds and which may be attributed to some of the phenomena of fecundation, and (2) the variegation which appears in buds, generally designated as sports. An account is given of observations in a nursery in which variegated forms appeared of the common plum, quince, *Cerasus acida*, *Catalpa bignonioides*, *Ailanthus glandulosa*, *Populus canadensis*, and 2 varieties of elm. The variation noticed in these trees was that presented in the second category, viz, the occurrence of sports, and although the same trees were cultivated in neighboring nurseries and different parts of the same the variegation was noticed in only one particular region. It is believed that there must have been some substance present in the soil which was taken up by the roots and carried throughout the plants, affecting the distribution of the chlorophyll. This substance is believed to be some form of xymase and by the

presence of this is to be explained the transmission of variegation by means of grafts and cuttings.

Experiments on cereal improvement at Olbersdorf, G. SWOBODA (*Ztschr. Landw. Versuchs. Oesterr.*, 5 (1902), No. 11, pp. 1272-1288).—A detailed account is given of experiments which have been carried on at the station of Olbersdorf in the improvement of varieties of cereals. Spelts and oats were the subject of the improvement experiments, the object being to secure varieties better adapted to cultivation under conditions of elevation, temperature, etc., which prevail at that station. Potatoes were also experimented with, but are not reported upon in any detail.

The germination of potato tubers, H. VÖCHTING (*Bot. Ztg.*, 1. Abt., 60 (1902), No. 5, pp. 87-114, pls. 2; *abs. in Jour. Roy. Micros. Soc.* [London], 1902, No. 4, p. 352).—There was found to be a close correlation between the temperature and the manner of development of the shoots springing from potato tubers. At a temperature which only slightly exceeded the lower limit at which germination begins only tuber-bearing shoots were produced, while at the optimum temperature these shoots were exclusively developed. In the former case the root development of the plants was very small, while in the latter roots were abundantly developed. The amount of water in the soil was also found to be closely related to the mode of growth. If little or no water was present there was but slight development of roots, and no leaf shoots were formed, but only tubers. On the other hand, with a plentiful supply of water, numerous roots and leaf shoots appeared but no tubers. An increase in the supply of moisture in the air was found to favor the development of leaves on the shoots where only scales were formed in insufficient moisture. The amount of oxygen in the atmosphere was found to exert no appreciable influence during the course of germination.

Aleurone grains in oily seeds, B. GRAM (*K. Danske Vidensk. Selsk. Skr.*, 6. ser., 9 (1901), pp. 303-336, pls. 4; *abs. in Jour. Roy. Micros. Soc.* [London], 1902, No. 4, pp. 442, 443).—The author has examined the character and reaction of the tegument, fundamental mass, globoid, crystal, etc., elements of oil-bearing seeds. The seed coat was found to be highly refractory. The fundamental mass consisted mainly of albuminoids which showed different degrees of solubility in dilute caustic potash for the different kinds of seed. In the globoid not only were the acid phosphates of calcium and magnesium found, but also succinic acid, and from their behavior with various solvents the globoids seemed to have a uniform composition. The investigations relating to the presence of alkaloids were of a negative character. From the crystals present succinic and oxalic acids and magnesium, calcium, and potassium were obtained. The difference in resistance of the crystals to different reagents is due to differences in their chemical composition. In most cases the author concludes that the crystalloids are of a very complex nature.

Enzyms of the tea leaf, H. H. MANN (*Jour. Asiatic Soc. Bengal*, 70 (1901), II, No. 2, pp. 154-166).—After briefly reviewing the chemistry and physiology of the tea leaf, the author gives an account of investigations on the enzymes which are found in the tea leaf and to which the character of the prepared tea is said to be due. It is said that an oxydase occurs in the leaf of the tea plant, and that this is the principal agent which causes fermentation and coloring of the leaf. It is most active at temperatures below 55° C., and is destroyed at a temperature of 80°. It occurs in greatest abundance in the unopen leaves at the tip of the shoot. The quantity decreases as the leaves grow older, but the leafstalks contain almost the same amount as the tip leaf. In leaves of the same general type those which contain the most of the enzyme make the most highly flavored tea, and the increase in the enzyme of the leaf seems to be related to the amount of phosphates in the soil. The amount of enzyme in the leaf increases rapidly during the process of withering the leaves, a fact that makes it probable that this ferment performs much more important functions in the manufacture of tea than has hitherto been believed. Other enzymes were found to occur in the tea leaf, but as yet no evidence has been obtained to show that they are of great importance in tea manufacture.

Alinit, C. SCHULZE (*Centbl. Agr. Chem.*, 31 (1902), pp. 145-147; *abs. in Jour. Roy. Micros. Soc.* [London], 1902, No. 5, p. 603).—The author states that the Alinit bacillus requires organic nitrogenous matter for its growth and fails to grow in nonnitrogenous solutions. Wheat was grown in pots containing Ellenbach soil and ground sandstone, which were divided into the series of sterilized, inoculated, and check. At the conclusion of the experiments it was found that although all the pots contained molds and various bacteria, the alinit bacillus predominated. No fixation of free nitrogen had taken place, but on the contrary there was a distinct loss of nitrogen. Similar results were obtained in pot experiments exposed to the air, and negative results were obtained in a set of experiments to determine the effects of carbohydrates as well as in field experiments of barley and oats.

Energy of assimilation in fungi, T. BOKORNY (*Arch. Physiol.* [Pflüger], 89 (1902), No. 9-10, pp. 454-474; *abs. in Jour. Roy. Micros. Soc.* [London], 1902, No. 5, p. 587).—It was found that the assimilation energy measured by the relative increase in weight is much greater for molds and yeasts than for green plants. A mold grown in a medium containing glycerol and ammonium sulphate increased in weight 1,000 times in 28 days. Yeasts increased most rapidly in the presence of cane sugars when the nitrogenous food present was peptone. Asparagin is said to be less favorable, and ammonium sulphate least of all. Spirogyra is said to be able to assimilate its carbon from sodium formaldehyde sulphonate in the absence of carbon dioxide, starch being formed in the cells. In 5 days 0.07 gm. of a dried plant produced 0.11 mg. of starch.

Resistance of molds to metallic poisons, C. PULST (*Jahrb. Wiss. Bot.* [Pringsheim], 37 (1902), No. 2, pp. 205-263; *abs. in Jour. Roy. Micros. Soc.* [London], 1902, No. 4, p. 472).—Cultures were made of *Mucor mucedo*, *Aspergillus niger*, *Botrytis cinerea*, and *Penicillium glaucum* to test the effect of metallic poisons upon their development. The sulphates of copper, zinc, iron, etc., were mixed with the substratum upon which the molds were grown, and the effect noted upon the subsequent development. The results showed that *Penicillium glaucum* possessed the greatest power of resistance, and the other 3 were extremely sensitive to the influence of metallic poisons. It was further found that molds, particularly *Penicillium*, have the power of accommodating themselves to the medium in which they are grown, and the limit of resistance rises with each generation of the fungus.

The influence of a medium on the respiration of molds, S. KOSTYTSCHEW (*Ber. Deut. Bot. Gesell.*, 20 (1902), No. 6, pp. 327-334).—Experiments are reported with *Mucor stolonifer* and *Aspergillus niger* in which the author sought to ascertain whether there was any relation between the intramolecular respiration of these molds and the alcoholic fermentation of yeasts. The molds were grown upon various media in an atmosphere free from oxygen, and the effect of different substances as influencing the respiration is shown. There was no evidence found to indicate that intramolecular respiration and alcoholic fermentation are identical.

A few common fleshy fungi of Ames, ALICE W. HESS (*Iowa Sta. Bul.* 61, pp. 148-153, figs. 5).—Descriptive notes are given on a number of fungi, among them *Coprinus micaceus*, *Morchella esculenta*, *Pleurotus ostreatus*, *P. sapidus*, and *P. ulmarius*, also *Agaricus campestris*, *Lycoperdon giganteum*, and *Lepiota morgani*. This last species is considered by many to be poisonous, although, according to the author, it has been eaten without injury by a number of individuals.

New species of fungi from various localities, J. B. ELLIS and E. BARTHOLOMEW (*Jour. Mycol.*, 8 (1902), No. 64, pp. 173-178).—Descriptions are given of about 2 dozen new species of fungi, most of which are saprophytic, but a few are said to occur parasitically on living leaves and other parts of plants of economic value.

A monstrosity of *Boletus luteus*, C. VAN BAMBEKE (*Bul. Soc. Roy. Bot. Belg.*, 39 (1900), I, pp. 7-21, pl. 1).—An account is given of an unusual form of *Boletus luteus* which is caused by the parasitism of the fungus *Hypomyces chrysospermus*.

Report of the New York State botanist, C. H. PECK (*Bul. New York State Mus.*, 10 (1901), No. 54, pp. 931-984, pls. 7).—Lists are given of the plants added to the herbarium during the year covered by the report, together with notes on species not hitherto reported as occurring within the State; also descriptions of new species and remarks and observations on old species. A number of species of edible fungi are described in detail, and illustrated by colored plates.

Report of the botanist, F. M. BAILEY (*Queensland Agr. Jour.*, 11 (1902), No. 6, pp. 401-403).—A summary is given of the activity of the botanist during the season covered by the report, and particular attention called to the numerous requests for the identification of suspected poisonous plants. On account of the prevailing drought resulting in a scarcity of food, stock has browsed upon many plants which in ordinary seasons would not have been touched. This has led to many suspected cases of poisoning. In some instances the plants have been found of a poisonous character, but the really injurious ones have been few in number.

FERMENTATION—BACTERIOLOGY.

Bacteriological investigations of the Ames sewage-disposal plant, L. H. PAMMEL (*Centbl. Bakt. u. Par.*, 2. Abt., 9 (1902), No. 3-4, pp. 89-107, pls. 3).—A description is given of the sewage-disposal plant at Ames, Iowa, and of the results of bacteriological studies. The number of bacteria per cubic centimeter is reported for the different months, and the daily variation is shown in tabular form. No attempt was made to identify all species of bacteria found in the effluent, although *Bacillus liquefaciens fluorescens* and *B. subtilis* and several species of *Sarcina* were found quite commonly. Chemical analyses are reported of samples of water taken from time to time, which tend to show the uniformly high efficiency which the plant has attained, particularly in the consumption of albuminoid ammonia, etc. The bacteriological results show that all but an insignificant part of the bacteria are removed by this sewage-disposal plant, the degree of purification ranging from 99 to 99.55 per cent.

Bacteriological studies at the Lawrence experiment station, S. DEM. GAGE (*Massachusetts State Bd. Health Rpt. 1901*, pp. 397-420).—A number of papers are given in which changes are suggested in the methods for the eradication of *Bacillus coli* in water, and a review given of *B. coli* studies, as well as on methods for the differentiation of bacteria. A proposed system of classification of bacteria is described, and technical descriptions given of a number of species of bacteria which have been isolated during the routine studies of the station.

The penetration of plant tissues by bacteria, G. ELLRODT (*Centbl. Bakt. u. Par.*, 2. Abt., 9 (1902), No. 17-18, pp. 639-642).—On account of the reputed possibility of the transmission of bacterial diseases of man and animals through eating uncooked vegetable matter that had been grown in infested soils, the author studied a number of plants in pots watered with exceptionally active cultures of *Bacterium pyocyaneum*. Oats, beans, vetches, peas, violets, peonies, and iris were experimented with. The plants were grown until well established, after which the bacterial cultures were added to the soil. After a further period of growth the plant tissues were examined for bacteria. Although the bacteria were found to grow in the soil, none was found in the tissues of the plants experimented with so long as their roots remained uninjured. This seems to indicate that at least this species of bacteria is not able to penetrate the root tissues and thereby get into the above-ground parts of plants.

Assimilation of free nitrogen by bacteria, M. W. BEIJERINCK and A. VAN DELDEN (*Centbl. Bakt. u. Par.*, 2. Abt., 9 (1902), No. 1-2, pp. 3-43).—Studies are reported on the ability of a number of bacteria to assimilate free atmospheric nitrogen, the authors investigating various forms of *Chroococcus* in particular. These organisms

were cultivated in nutrient media as pure cultures, pasteurized cultures, and mixed cultures, and the power of nitrogen assimilation shown. The amount of nitrogen added by the organisms to the media varied considerably, especially with the mixed cultures, the limits being from 0.73 to 6.93 mg. per gram of glucose or mannite in the solution. In the pasteurized cultures the range of variation was from 0.17 to 4.93 mg., while in the pure cultures or combinations of known species the range was from 0 to 5.91 mg. per gram of glucose or mannite. The possibility of symbiosis between forms of *Chroococcus* and other organisms was not proved.

Observations on the conditions of light production in luminous bacteria, R. E. B. MCKENNEY (*Proc. Biol. Soc. Washington*, 15 (1902), pp. 213-234, fig. 1).—A study is reported of a number of so-called phosphorescent bacteria in which the author investigated their culture and the effect of various agents upon their luminescence. It was found that all acids, as well as an excess of alkali, were injurious to light production. The temperature limits for light emission are within those necessary for growth. Exposures to temperatures above the growth maximum were highly injurious to the power of light production, while exposure to low temperatures seemed to serve as a stimulus to light production. There was no luminescence at or below 0° C. A certain degree of continued illumination was found without effect, and it is possible for the bacteria to pass their entire lives in the dark and yet emit a brilliant light. Ether acts as a narcotic, preventing luminescence but not growth. Peptone or a related protein was found requisite for the nutrition of luminous bacteria, and either sodium or magnesium is required for growth and especially for light production. Potassium, ammonium, calcium, etc., can not replace sodium or magnesium. The author believes that luminescence is connected with metabolism, and since its appearance is closely followed by the presence of the culture liquid of the products of protein decomposition it is believed to be a phase of destructive metabolism.

The strawberry bacillus, W. EICHMOLZ (*Centbl. Bakt. u. Par.*, 2. Abt., 9 (1902), No. 11-12, pp. 425-438, figs. 2).—A description is given of the growth and morphological characters of the so-called strawberry bacillus on a number of different culture media.

A review of existing methods for cultivating anaerobic bacteria, O. F. HUNZIKER (*Reprint from Jour. Appl. Micros. and Lab. Methods*, Vol. 5, Nos. 3, pp. 1694-1695; 4, pp. 1744-1758; 5, pp. 1800-1814; 6, pp. 1854-1856).—The author presents an elaborate discussion of the literature of this subject in connection with an extensive bibliography. The methods for producing anaerobic conditions which are discussed in the article include the formation of a vacuum, replacement of air by inert gases, absorption of oxygen, reduction of oxygen, exclusion of atmospheric oxygen by means of various physical and mechanical devices, and the combined application of 2 or more of these methods. Special attention is given to methods of cultivating the bacilli of tetanus and anthrax.

Investigations on the physiology and morphology of alcoholic ferments, E. C. HANSEN (*Compt. Rend. Travaux Lab. Carlsberg*, 5 (1902), No. 2, pp. 64-67, figs. 10).—An account is given of the spore formation of certain species of *Saccharomyces*.

Comparative investigations on the condition of growth and reproduction of yeasts, etc., E. C. HANSEN (*Compt. Rend. Travaux Lab. Carlsberg*, 5 (1902), No. 2, pp. 68-70, figs. 1).—The author has investigated the conditions for the vegetative growth and development of the organs of reproduction in yeasts and other alcoholic ferments. Recent investigations regarding budding, spore formation, and the relation between budding and spore formation, are given, and the effect of temperature on these factors is shown. As a rule the maximum temperature for the vegetative growth of *Saccharomyces* was found to be higher than that for the formation of

The influence of external factors on the assimilation of yeasts, T. BOKORNY (*Centbl. Bakt. u. Par., 2. Abt., 9 (1902), Nos. 1-2, pp. 55-62; 3-4, pp. 117-126, fig. 1*).—The concentration of the culture medium, action of poisons like formalin, alkaloids, etc., the presence of acids beyond a very weak concentration, and of alcohol in a concentration of more than 5 per cent, were found to check the assimilative action of yeasts. It was found that like green plants the variation of temperature played an important part, the maximum assimilation taking place at 20 to 25° C., while at 40° it was checked and at 20° was nearly at the minimum.

The Benikoji fungus, Y. UYEDA (*Bot. Mag. [Tokyo], 15 (1901), pp. 160-163; 16 (1902), pp. 79, pl. 1; abs. in Jour. Roy. Micros. Soc. [London], 1902, No. 4, p. 466*).—An account is given of the fungus used in making a Chinese fermented drink known as anchu from rice in Formosa. Several fungi were found to take part in the process, but the chief agent of fermentation was said to be a species of *Monascus*. In cultivation the fungus produces sporangia, which become reddish in color, surrounded by an envelope of loose hyphæ. The author believes the fungus is identical with *Monascus purpureus*, and besides this fungus there were 2 forms of yeast present. The yeast most frequently observed is believed to be nearly allied to *Saccharomyces rosaceus*.

AIR—WATER—SOILS.

On the question of hydrogen in the atmosphere, LORD RAYLEIGH (*Phil. Mag. and Jour. Sci., 6. ser., 3 (1902), No. 16, pp. 416-422*).—The results of spectroscopic observations and combustions with copper oxid are reported as a basis for the inference "that the free hydrogen in country air does not exceed 1/30,000 of the volume."

On atmospheric hydrogen, A. LEDUC (*Compt. Rend. Acad. Sci. Paris, 135 (1902), No. 20, pp. 860, 861*).—The results obtained by the author by means of direct determination of oxygen and calculation from various equations confirm those of Lord Rayleigh in indicating that the proportion of hydrogen in the atmosphere is much smaller than is claimed by Gautier, who reports about 1 cc. in 5 liters.

On the quantity of free hydrogen in the air and the density of atmospheric nitrogen, A. GAUTIER (*Compt. Rend. Acad. Sci. Paris, 135 (1902), No. 23, pp. 1025-1032*).—A reply to the statements of Lord Rayleigh and Leduc, noted above.

Researches on the blue color of the sky, G. ZETTWICH (*Phil. Mag. and Jour. Sci., 6. ser., 4 (1902), No. 20, pp. 199-202*).—This is an abstract of a thesis for the doctor of science degree of the University of Rome, which gives an historical review of the subject, its present status, and an account of experimental researches on the subject directed mainly toward the verification of Rayleigh's dynamical theory.

The chemical and geological history of the atmosphere, J. STEVENSON (*Phil. Mag. and Jour. Sci., 6. ser., 4 (1902), No. 22, pp. 435-451*).—In a previous paper (*E. S. R., 12, p. 426*) the author stated the reasons for believing that the primitive atmosphere of the earth contained no free oxygen, but considerable quantities of hydrogen or hydrocarbon gases. The present paper discusses the extent and composition of the primitive atmosphere, the conclusion being "that the primitive atmosphere was most probably a very extensive one, perhaps a hundred or several hundred times greater in extent than our present atmosphere. It may have consisted principally of carbonic acid, or it may have contained, either in addition to or instead of carbonic acid, large quantities of hydrogen, hydrocarbon gases, and carbonic oxid. At present our information regarding the data bearing on this question is not definite enough to decide the point with certainty, but we may reasonably hope that sufficient evidence will sooner or later accumulate to give a fairly decisive verdict."

The climate and artesian waters of Australia, J. P. THOMPSON (*Queensland Geogr. Jour., n. ser., 17 (1902), No. 3, pp. 1-32*).—The sources of meteorological data

relating to Australia are noted and its general climatic conditions, especially as regards rainfall, are discussed. The geological and physical characteristics of the great central artesian basin of Australia are discussed in detail. Among the conclusions reached are:

"That a comparatively small percentage of the rainfall over the interior of the continent is absorbed by the exposed marginal outcrops and carried to the retaining gravel beds that underlie the clays, and when these overlying impervious strata are pierced by the borer's drill, at lower levels than the source of supply, the impounded waters beneath the clayey strata flow to the surface.

"That from the elevated intake beds there is a very slow circulation of the underground waters toward the lower levels of the central portion of the continent, where there is leakage in the form of natural artesian springs and marshes—such being favored by the local conditions to which I have alluded.

"That, besides these natural springs at the bottom of the great central trough, there are others where weak portions of the strata occur within the region.

"That the great storage beds are periodically replenished by the quantity of water absorbed at the outcrops.

"That the absorbing process is temporarily suspended when the water-carrying beds have been filled.

"That there is upward as well as downward percolation of artesian water.

"That by far the greater portion of the rainfall over the inland regions of Australia and the leakage waters from the storage beds are evaporated.

"That there is no available evidence of submarine leakage of the artesian waters of Australia.

"That, on the contrary, the balance of evidence and of reasons is directly opposed to the theory of such leakage."

Chemical-geological investigations on the absorptive properties of decomposed rocks. M. DITTRICH (*Mitt. Grossherz. Bad. Geol. Landes-Aufnahme*, 4, No. 3; *abs. in Cembr. Agr. Chem.*, 31 (1902), No. 12, pp. 793-796).—In these investigations 25 gm. of weathered rock (hornblende granite) was treated at room temperatures for 2 days with normal, $\frac{1}{10}$ -normal, and $\frac{1}{100}$ -normal solutions of sodium, potassium, ammonium, calcium, and magnesium chlorids; and potassium nitrate, sulphate, and carbonate, the composition of the extract thus obtained being determined. With tenth-normal sodium chlorid solution considerable amounts of lime and magnesia were dissolved, while an equivalent amount of soda was retained by the rock, and only traces of potash were found in the extract. These changes took place very soon after the solution was added, and with 8 days' digestion the results were the same as with 2. With the hundredth-normal solution the amount of lime dissolved was increased, while with normal solution it was decreased. With potassium chlorid solutions the reactions were much the same in kind as with sodium chlorid solutions and proceeded more rapidly. Despite the fact that the rock was already rich in potash, it absorbed considerable amounts of potash from the solution. The amounts of lime and magnesia dissolved were double those removed by the sodium chlorid solution. The behavior of ammonium chlorid solution was similar to that of potassium chlorid. In both cases there was apparently a chemical union of the base with the constituents of the rock. Little change was observed in case of the solutions of calcium and magnesium chlorids. Potassium nitrate and sulphate behaved like the chlorid, indicating that with neutral salts the reactions depend upon the base and not upon the acid. With calcium carbonate, an alkaline salt, almost no lime and magnesia were dissolved, but more than a third of the potash, with a corresponding amount of carbon dioxide, were absorbed by the rock.

Geology and water resources of the Snake River Plains of Idaho. I. C. RUSSELL (*U. S. Geol. Survey Bul.* 199, pp. 192, pls. 25, figs. 6).—This report is based on the results of field work carried on from July 5 to September 12, 1901, the main

objects of which "were to ascertain how far the geological conditions, particularly beneath the broad lava-floored plains bordering Snake River, favor the hope of obtaining flowing water by drilling wells, and where test wells should be put down in order to determine the correctness of inferences based on geological and other conditions." Especial attention is given to the physiography and geology (including soils) of the region, which is described as "a generally flat area bordered by rugged mountains" extending "in a curved course concave to the north entirely across the southern portion of Idaho. The length of this belt measured along its medial line is about 350 miles, and the width is generally from 50 to 75 miles. Its area, as estimated by Lindgren, is 34,000 square miles. Snake River traverses this rudely crescent-shaped plain throughout its length in a great curve concave to the north, which has a radius of some 175 miles. In a far-reaching view the flat country through which the Snake River finds its way presents the broader features of a vast level-floored, stream-eroded valley. A nearer acquaintance, however, shows that it is a built-up plain, formed principally of lava sheets, and does not owe its major surface features to erosion. . . .

"The geological discussion of the Snake River Plains may be consistently divided into 2 portions, the first dealing with the older rocks which were upraised into mountains and deeply eroded before the partial filling of the Snake River Basin, and the second with the lacustral and stream deposits, lava sheets, etc., now forming the plains themselves. The former, in geological language, embraces mostly, if not entirely, paleozoic rocks; and the second, tertiary and recent rocks. Between the formation of these 2 great rock divisions there was a long interval, during which deep erosion and the development of a rugged topography took place. . . .

"The climate of the Snake River Plains has for its leading characteristics aridity, prevailing high temperatures in summer, and severe cold in winter. One of the most marked features in the atmospheric conditions at nearly all seasons is the great range in temperature between day and night. The mean annual precipitation is about 13 in., but many local variations occur. Nearly all the water that reaches the thirsty lands comes in winter and spring. During the growing season the soil is invariably parched, and successful agriculture without irrigation is seemingly impossible. . . . However, over the higher portion of the plains lying southwest of Big Butte the rainfall may be sufficiently above the average, or the soil may retain enough moisture, or possibly the slow melting of the winter snow may furnish the proper conditions to permit the growing of wheat and other cereals without irrigation. . . . As agriculture is at present entirely dependent on irrigation, cultivated land occurs only where water from streams and springs can be obtained. . . .

"In general the soil of the plains is a fine, yellowish-white, silt-like material, largely a dust deposit, which mantles the surface not only on level tracts but covers hills and broad depressions alike. This material is similar to the celebrated loess of China, except that it usually occurs as a comparatively thin layer, and resembles also the deposit bearing the same name in the Mississippi Valley. Like each of these formations, it is of exceptional fertility if properly irrigated. . . .

"The soils of southern Idaho are of 2 classes—sedentary and transported. Of the transported soils, there are again 2 principal subdivisions—wind-deposited and water-deposited. Of the wind-carried or æolian soils there are 2 principal varieties, one consisting mainly of fine quartz sand and the other of volcanic dust and lapilli. Of the water-deposited soils there are again 2 varieties—those laid down in lakes, principally in southwestern Idaho, and those deposited by streams. The principal part of the soil covering the plains at a distance from the mountains and outside the canyons is of æolian origin, and consists mainly of fine quartz particles."

It is stated that what are commonly termed alkali incrustations are absent from the soils of the region under normal conditions, although the occurrence of two chemically-formed subaerial deposits are described, one a white or yellowish-white

deposit of carbonate of lime "found almost everywhere on the under sides of loose stones or in the upper portions of basaltic outcrops when covered with loose stones, sand, soil, etc.," and the other a deep-blue film consisting of salts of iron and manganese, occurring on the surface of the less recent lava.

The author concludes from his study of the water resources of the region that "the surface water supply at present available is largely wasted, and can by proper economy be made to yield 2 or 3 times the service now obtained from it." He believes "it is practicable to use for irrigation the entire summer flow of all the streams reaching the Snake River Plains." Another means of more fully utilizing the water supply is by constructing reservoirs, suitable sites for which have been located. There is evidence that the supply may be still further largely increased by the sinking of properly constructed artesian wells.

Studies on humus, T. SCHLOESING (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 16, pp. 601-605).—Using methods similar to those employed in the study of the distribution of iron oxid in soils (E. S. R., 14, p. 18), the author found that in humus soils the proportion of organic matter adhering to the soil particles increases as the size of the particles decreases, i. e., from 0.4 per cent in the coarse sand particles to 5.4 per cent in the clay of one soil, and from 0.15 per cent in the coarse sand to 4.14 per cent in the clay of another. The method used in separating the different grades of particles is described. Potassium chlorid (5 gm. per liter) was successfully used to precipitate the clay particles without simultaneous precipitation of alkaline humates. The organic matter adhering to the particles was determined by combustion with copper oxid in the usual way, it being assumed in the calculation of the results that the organic matter contained 50 per cent carbon. The author advances the theory that the organic matter adhering to the soil particles has been precipitated upon them from the soil solutions and is alternately dissolved and precipitated as the soil solutions become diluted or concentrated. If this be true, it constitutes an important reserve or store of plant food.

A contribution to the study of tropical soils, J. D. KOBUS and T. MARR (*Jour. Landw.*, 50 (1902), No. 4, pp. 289-302).—This article briefly discusses the value of chemical analysis as a means of determining the fertilizer requirements of soils, reviewing investigations on the subject, and reports the results of analyses of the solutions obtained by 5 successive extractions of 2 Javanese soils of volcanic origin with 2, 4, and 8 per cent hydrochloric acid, boiling for 2 hours, in each case, and by 24 hours extraction with cold concentrated hydrochloric acid. The proportion of solvent used was larger than that ordinarily employed. The author concludes that the 2 per cent acid extract gave results most accurately indicating the available potash and phosphoric acid of the soils.

Banana soils of Jamaica, II, H. H. COUSINS (*Bul. Dept. Agr. Jamaica*, 1 (1903), No. 1, pp. 1-17).—A preliminary analysis of some of the banana soils of Jamaica has been previously announced (E. S. R., 13, p. 633). The work has been continued, and in the present report physical and chemical analyses are given of about 30 of the most prominent banana soils of Jamaica. Fertilizer experiments were carried out on the soils examined. The results indicate that as a whole commercial fertilizers need not be used on Jamaica soils in the production of bananas for many years to come. The soil analyses, considered in the light of subsequent fertilizer experiments based on them, are believed to show that the analyses alone are sufficient evidence on which to base practical advice as to soils for banana cultivation.

Greensand marl, A. L. PARSONS (*Mineral Resources of the United States. Dept. Interior, U. S. Geol. Survey*, 1901, pp. 823-827).—This article briefly discusses the occurrence and classification of greensand formations and the production and use of the marls. Compiled analyses of characteristic marls from New Jersey, Maryland, and Virginia, and a bibliography are given.

Further contribution to the question, Can plant analysis show the fertilizer requirements of soils? C. VON SEELHORST, H. BEHN, and J. WILMS (*Jour.*

Landw., 50 (1902), No. 4, pp. 303-322).—The article reviews recent contributions by other investigators to this subject, and reports a continuation of the experiments of the authors (*E. S. R.*, 10, p. 1033). The conclusion is reached that the yield and composition of the plant substance is so influenced by meteorological conditions that plant analysis alone is of little practical value in determining the fertilizer requirements.

Root-tubercle bacteria in their relation to soils and fertilizers, WOHLTMANN and BERGENÉ (*Jour. Landw.*, 50 (1902), No. 4, pp. 377-395).—Pot experiments are reported with peas on 11 different kinds of soils, one series of which was unfertilized and other series fertilized with ammonium nitrate, Thomas slag, and potassium phosphate. The composition of the soils and data regarding the development of root tubercles on the plants are reported in detail. The uncultivated soils were found to be poor in tubercle bacteria; a fair proportion of humus favored tubercle development, but there was little or no tubercle development in soils very rich in humus; excluding the moor soils, the nitrogen content appeared to be without influence on tubercle development; on all soils no tubercles were produced when ammonium nitrate was applied. Potash, phosphoric acid, and lime favored the production of root tubercles.

Bacteria of the soil in their relation to agriculture, F. D. CLESTER (*Pennsylvania Dept. Agr. Bul.* 98, pp. 88, pls. 9).—This is a summary of present information on this subject, to which is added an extended bibliography. (See also *E. S. R.*, 10, p. 334; 11, p. 435; 12, p. 729; 14, p. 232.)

FERTILIZERS.

Fertilizers (*Twelfth Census United States, Census Rpts.*, vol. 5 (*Agriculture*, pt. 1), pp. CXXXVI-CXLII).—This article discusses the history and the general theory of the use of fertilizers, in addition to giving statistics of use. The total expenditure for fertilizers in the United States in 1899 is given as \$54,783,757, or \$10 per farm, 7 cts. per acre of farm land, and 1.2 per cent of the total value of farm products. The expenditure was distributed as follows: North Atlantic States, \$15,641,995; South Atlantic States, \$22,732,670; North Central States, \$7,273,695; South Central States, \$6,711,824; Western States, \$1,070,726; and Hawaii, \$1,352,847. The outlay for fertilizers has, according to these figures, increased 42.4 per cent since 1890. "Of the farms classified by principal source of income, sugar farms reported expenditures greatly in excess of those of other farms. The average for all farms was only \$10, while that for sugar farms was \$280. The next largest expenditure was \$69, for nurseries; florist's establishments expended \$51; vegetable farms, \$38; tobacco farms, \$27; fruit farms, \$22; rice farms, \$13; and coffee, cotton, and dairy farms, \$11. The lowest averages reported were \$6 for hay and grain farms, and \$5 for live stock and tano farms. . . . The average expenditure per acre was greatest for farms of cash and share tenants and least for farms of part owners and managers. The average per farm was greatest for farms of managers and least for those of part owners and share tenants. The percentage of the value of products expended for fertilizers was largest for farms of managers and least for those of part owners."

Analyses and valuations of fertilizers, L. A. VOORHEES and J. P. STREET (*New Jersey Stat. Bul.* 163, pp. 55).—This bulletin discusses the trade values of fertilizing ingredients in 1902; the cost, valuation, purchase, and guaranteed and actual composition of fertilizers, home mixtures, and special fertilizers; and reports the results of examination of 60 samples of standard unmixed fertilizing materials, 391 brands of complete fertilizers representing 95 manufacturers, 26 samples of ground bone, and 48 samples of miscellaneous products. In addition there are reported the analyses of 3 samples of home mixtures and 20 samples of mixtures especially compounded by manufacturers to order. The materials included, in addition to the mixed ferti-

lizers, nitrate of soda, dried blood, dried and ground fish, tankage, superphosphates, muriate of potash, sulphate of potash, kainit, limekiln ashes, wood ashes, prepared lime, prepared lime and potash, oyster-shell lime, blue lime, tannery refuse, garbage ashes, oil-cake waste, wool waste, soot, bone residue, tobacco stems, and bat guano. About 31 per cent of the brands of fertilizers examined were deficient in one or more of the different forms of plant food. The averages for all brands of complete fertilizers examined during 1902 are as follows: Total nitrogen, 2.38 per cent; total phosphoric acid, 10.47 per cent; available phosphoric acid, 8.09 per cent; insoluble phosphoric acid, 2.38 per cent; potash, 5.32 per cent; station valuation, \$21.32; selling price, \$27.66. It appears "that the manufacturers are delivering, on the average, somewhat less total plant food than in 1901, at a slight advance per ton."

Analyses of commercial fertilizers, J. HAMILTON and W. FREAR (*Pennsylvania Dept. Agr. Bul. 101, pp. 137*).—A report on inspection of fertilizers in Pennsylvania during the six months ended July 31, 1902, including analyses of 450 samples with a discussion of the results and notes on valuation of fertilizers in 1902.

Commercial fertilizers, H. J. WHEELER ET AL. (*Rhode Island Sta. Bul. 39, pp. 53-66*).—This bulletin contains analyses of a portion of the fertilizers collected during 1902. The fertilizers examined during this year showed a very marked improvement over last year.

Analysis of commercial fertilizers (*South Carolina Sta. Bul. 73, pp. 14*).—This bulletin reports analyses and valuations of 175 samples of fertilizers collected during the season of 1901-2.

Should manure be plowed under as soon as it is carried to the field? T. REMY (*Deut. Landw. Presse, 30 (1903), No. 5, pp. 31, 32*).—Experiments with potatoes are reported which show that the best results, both as regards yield and starch content, were obtained when the manure was incorporated with the soil at once as compared with composting or allowing the manure to lie on the soil some time before being plowed under.

Comparative value of different phosphates, C. A. MOOERS (*Univ. Tennessee Record, 6 (1903), No. 1, pp. 20-24, figs. 4*).—This article discusses sources and nature of different phosphates and their relative value as fertilizers; reviews briefly previous experiments with phosphates; and gives results of pot tests at the Tennessee Station of superphosphates, precipitated phosphate, bone meal, and ground rock on cowpeas and turnips. The results with both crops showed no appreciable benefit from applications of from 300 to 1,200 lbs. of ground rock per acre. "On the other hand, 300 lbs. of high-grade acid phosphate gave a marked increase in the yield above any of the other plats." Finely ground bone meal gave excellent results. "For cowpeas 2 lbs. of phosphoric acid from the meal was found to be about equal to 1 lb. from acid phosphate. The turnips, however, seemed somewhat less able than the peas to use the phosphoric acid of the meal. Precipitated phosphate gave much better results than bone meal, and as would be expected the water-soluble phosphate of lime gave excellent returns, but whether the best, considering the quantity used, can not now be told."

What is the value of the water-insoluble phosphoric acid of double superphosphates? B. SCHULZE (*Deut. Landw. Presse, 30 (1903), No. 2, pp. 12, 13*).—Pot experiments with oats are reported in which phosphoric acid was applied, with and without the addition of lime, as superphosphate and in form of the residue from extraction of the water-soluble phosphoric acid from double superphosphate. The author concludes that the phosphoric acid of double superphosphate insoluble in water has usually one-third the fertilizing value of water-soluble phosphoric acid, which may be increased to one-half with cereals under favorable conditions and in case of phosphoric-acid hunger.

Phosphate rock, J. STRUTHERS (*Mineral Resources of the United States. Dept. Interior, U. S. Geol. Survey, 1901, pp. 811-822*).—Statistics of production in the United

States and the world, and prices and imports are given for a number of years. The total production in the United States in 1901 was 1,483,723 long tons, valued at \$5,316,403, as compared with 1,491,216 tons, valued at \$5,359,248, in 1900. Of the total United States product in 1901, 751,996 tons was furnished by Florida, 321,181 tons by South Carolina, 409,653 tons by Tennessee, and 893 tons by Pennsylvania. The production of the United States exceeds that of the rest of the world combined.

The Stassfurt industry (*New York: German Kali Works, 1902, pp. 65, figs. 29*).—This is a brief summary of information regarding the discovery and beginnings of mining of the Stassfurt potash deposits, the origin and formation of the deposits, methods of mining, character of the salts mined, methods of manufacturing the concentrated salts, production and consumption of potash salts, the use of potash in agriculture, and the salts used for fertilizing purposes. According to the statistics given, the total production of crude salts (carnallit, kieserit, sylvinite, kainit, and hartsalz) of the Stassfurt mines in 1901 was 3,484,694 metric tons (of 2,204 lbs. each), of which 1,438,579 tons was used directly as fertilizer and the remainder, 2,046,115 tons, was used in the manufacture of concentrated salts (muriate and sulphate of potash, sulphate of potash and magnesia, potash manure salt, and kieserit), the total production of which in 1901 was 426,561 tons. Of the total amount of actual potash (K_2O) produced in 1901, 270,826 tons was used in agriculture and 72,323 tons in other industries. Germany used for agricultural purposes in 1900 117,712 tons of actual potash. The amount used for the same purpose in the United States in 1899 was 52,667 tons.

Gypsum, J. SPRUTHERS (*Mineral Resources of the United States. Dept. Interior, U. S. Geol. Survey, 1901, pp. 843-851*).—Statistics of production in the United States and the world and of imports are given. A remarkable increase in the production of gypsum in the United States during recent years is reported. "The total production of gypsum in the United States during 1901 was 659,659 short tons, valued at \$1,577,493, as compared with the total production during 1900 of 594,462 short tons, valued at \$1,627,203, which shows an increase of 65,197 short tons in quantity and a decrease of \$49,710 in value."

Yearbook on the use of commercial fertilizers, 1903, M. ULLMANN (*Jahrbuch über die Anwendung künstlicher Düngemittel, 1903. Hamburg: J. H. Koch & Co., 1903, pp. 32, figs. 13*).—This contains a calendar and gives brief simple directions, applicable especially to German conditions, regarding the use of commercial fertilizers on various crops, based largely on the work of the experiment station of Hamburg-Horn, of which the author is director. There is also a brief discussion of the possibility of Germany becoming agriculturally self-sustaining.

Consumption of fertilizers (*Amer. Fert., 18 (1903), No. 1, pp. 10-15*).—This article gives data compiled from the last United States Census, and reported by State inspectors of fertilizers and Departments of Agriculture and from other sources.

FIELD CROPS.

Results obtained in 1902 from trial plats of grain, fodder corn, field roots, and potatoes, W. SAUNDERS (*Canada Cent. Expt. Farm Bul. 41, pp. 61*).—This bulletin is the customary annual report of cooperative variety tests now in progress for 8 years at the Canada Experimental Farms (E. S. R., 13, p. 838). The yields of the different crops at the several farms are given in tables. The varieties producing the largest crops in 1902, taking the average results obtained on all the experimental farms and giving them in the order of their productiveness, were as follows:

Oats.—Siberian, Banner, Danish Island, Holstein Prolific, Golden Giant, Columbus, Golden Tartarian, Early Golden Prolific, New Zealand, Buckbee Illinois, Menonite, and Tartar King. Average yield per acre, 78 bu. 17 lbs. **Two-rowed barley**.—Danish Chevalier, Canadian Thorpe, Kinver Chevalier, French Chevalier, Invincible,

and Standwell. Average yield per acre, 50 bu. 12 lbs. *Six-rowed barley*.—Surprise, Odessa, Yale, Stella, Blue Long Head, and Brome. Average yield per acre, 53 bu. 23 lbs. *Spring wheat*.—Rio Grande, Roumanian, Colorado, Vernon, Goose, Preston, Plumper, Red Fern, Campbell White Chaff, Crown, Minnesota No. 181, and Herisson Bearded. Average yield per acre, 42 bu. 41 lbs. *Peas*.—Prince, Alma, White Wonder, Mackay, Arthur, Crown, Cooper, Harrison Glory, Agnes, Prince Albert, Pride, and Early Britain. Average yield per acre, 37 bu. 6 lbs. *Indian corn*.—Salzer All Gold, Thoro'bred White Flint, Early Butler, Eureka, Pride of the North, and Giant Prolific Ensilage. Average yield per acre, 19 tons 952 lbs. *Turnips*.—Good Luck, Magnum Bonum, Hall Westbury, Perfection Swede, Champion Purple Top, and Giant King. Average yield per acre, 30 tons 622 lbs. *Mangels*.—Lion Yellow Intermediate, Mammoth Long Red, Yellow Intermediate, Selected Yellow Globe, Mammoth Yellow Intermediate, and Champion Yellow Globe. Average yield per acre, 32 tons 714 lbs. *Carrots*.—Giant White Vosges, New White Intermediate, Iverson Champion, Green Top White Orthe, Improved Short White, and Mammoth White Intermediate. Average yield per acre, 23 tons 1,682 lbs. *Sugar beets*.—Royal Giant, Danish Improved, Danish Red Top, and Red Top Sugar. Average yield per acre, 24 tons 1,722 lbs. *Potatoes*.—Enormous, Irish Cobbler, Irish Daisy, Money Maker, Sharpe Seedling, Burnaby Seedling, Troy Seedling, Hale Champion, Dakota Red, Flemish Beauty, Rose No. 9, and Great Divide. Average yield per acre, 390 bu. 27 lbs.

The average results of the various crops for the last 3 to 8 years are also given. The following varieties, taking the average of the yields obtained on all the experimental farms, have been the most productive. *Oats*.—Banner, Danish Island, Mennonite, American Beauty, New Zealand, Holstein Prolific, Improved American, Black Beauty, Buckbee Illinois, Columbus, Thousand Dollar, and Golden Giant. Average yield per acre, 74 bu. 2 lbs. *Two-rowed barley*.—French Chevalier, Clifford, Dunham, Jarvis, Canadian Thorpe, and Harvey. Average yield per acre, 45 bu. *Six-rowed barley*.—Mensury, Claude, Mansfield, Odessa, Yale, and Trooper. Average yield per acre, 49 bu. 23 lbs. *Spring wheat*.—Roumanian, Laurel, Preston, Goose, Rio Grande, Monarch, Huron, Wellman Fife, Weldon, White Fife, Clyde, and Red Fife. Average yield per acre, 34 bu. 31 lbs. *Peas*.—Crown, Pride, Carleton, Picton, Early Britain, Chancellor, New Potter, Paragon, King, White Wonder, Pearl, and German White. Average yield per acre, 35 bu. 1 lb. *Indian corn*.—Early Mastodon, Salzer All Gold, Superior Fodder, Thoro'bred White Flint, Red Cob Ensilage, and Early Butler. Average yield per acre, 19 tons 887 lbs. *Turnips*.—Perfection Swede, Imperial Swede, Purple Top Swede, Halewood Bronze Top, Hall Westbury, and Bangholm Selected. Average yield per acre, 30 tons 1,267 lbs. *Mangels*.—Yellow Intermediate, Giant Yellow Intermediate, Lion Yellow Intermediate, Gate Post, Selected Mammoth Long Red, and Mammoth Long Red. Average yield per acre, 31 tons 292 lbs. *Carrots*.—New White Intermediate, Giant White Vosges, Half Long White, Improved Short White, Ontario Champion, and Mammoth White Intermediate. Average yield per acre, 22 tons 184 lbs. *Sugar beets*.—Danish Red Top, Danish Improved, Red Top Sugar, and Improved Imperial. Average yield per acre, 23 tons 1,383 lbs. *Potatoes*.—Uncle Sam, Irish Daisy, Seedling No. 7, American Wonder, American Giant, Seedling No. 230, Bovee, Country Gentleman, Rose No. 9, Late Puritan, Carman No. 1, and Seattle. Average yield per acre, 376 bu. 5 lbs.

"The evidence produced shows that there are great differences in the relative productiveness of varieties, when grown side by side under similar conditions, hence the importance to farmers of choosing for seed those which give the heaviest crops."

Report on the Cawnpore farm and other experiment stations in the United Provinces of Agra and Oudh 1902, W. H. MORELAND (Dept. Land Records and Agr., Cawnpore Farm Rpt., 1902, pp. 1-18).—The work here reported consisted of fertilizer experiments with wheat, corn, sugar cane, and potatoes, and variety and

culture tests with cotton, sugar cane, and various cereal and forage crops. The results obtained are tabulated in detail and the yields with each crop briefly noted.

Field trials at the Agricultural College of Norway, 1901, B. R. LARSEN (*Ber. Norges Landbr. Høiskoles Virks.*, 1901-2, pp. 255-298).—This report contains detailed accounts of variety tests of winter rye, hay crops, potatoes, and roots, and of comparative trials of different kinds, quantities, and mixtures of barnyard manure on grass land. Attention is also called to the main practical results of experiments in crop production and methods of cultivation conducted by the author since the establishment of the department in 1889.—F. W. WOLL.

Cooperative fertilizer experiments in Sweden, 1901, P. BOLIN (*K. Landt. Akad. Handl. Tidskr.*, 41 (1902), No. 3, pp. 137-279).—The report of fertilizer experiments with cereals and root crops, conducted under the direction of the Swedish Agricultural Academy during 1901, is presented. The experiments, comprising 243 different series with a total of 6,556 plats, were conducted by 199 farmers located in 15 different counties. Owing to an exceedingly dry season, the results were not all conclusive, but some general deductions are made from the successful trials. Nitrogen was generally applied in the form of nitrate of soda and in some cases in the form of poudrette, fish guano, and barnyard manure. It is believed that the luxuriant growth induced by nitrogen fertilization counteracts to a certain extent the retarding influence of drought. For this purpose, however, the nitrogen must be sufficiently soluble to be utilized by crops even if the amount of moisture in the soil is very small. The results show that nitrate of soda was quite effective in this respect. For spring grains harrowing in the nitrate of soda immediately before or after sowing was found a much safer method than to use it for a top-dressing, in which case the action of the fertilizer is largely dependent on the precipitation. For winter grains the top-dressing with nitrate of soda is likely to give good results if applied in the early spring, when the surface of the soil is still moist.

The phosphatic fertilizers applied were 20 per cent superphosphate, Thomas phosphate, and steamed bone meal. In general, the superphosphate applied at the rate of 200 kg. per hectare, furnishing 37 kg. of water-soluble phosphoric acid, produced better results with spring grains than 400 kg. of Thomas phosphate with 60 kg. of citrate-soluble phosphoric acid. The opposite effect was observed in a limited number of experiments conducted with winter grains. The residual effects of Thomas phosphate seemed to be more marked than those of superphosphate. The author recommends Thomas phosphate for soils low in lime and containing considerable iron oxid. In most cases the effect of bone meal was considerably decreased on humus soils when lime was applied at the same time. Bone meal generally produced somewhat poorer results than Thomas phosphate, and was in almost every instance the more expensive fertilizer. Detailed descriptions of the different experiments as to the fertilizers applied, yields, and quality of the crops grown are given.—F. W. WOLL.

Fertilizer tests with kainit and Thomas slag, V. VON KNIRIM (*Selsk. Khaz. i Ljessov.*, 206 (1902), Aug., pp. 401-426, Sept.; pp. 646-678; 207 (1902), Oct., pp. 215-228).—Tests with kainit and Thomas slag as fertilizers for rye, oats, barley, potatoes, clover, and grass were conducted by agricultural students under the direction of the author. From the results it is concluded that potash and Thomas slag are especially recommendable for clover fields and meadows; and that for spring cereals and potatoes they should be applied with superphosphate, and for winter cereals with superphosphate and bone meal. In the locality where these experiments were made the yields of clover, potatoes, and grasses are more easily increased than the yields of the cereals.—P. FIREMAN.

Rotation experiments, A. L. YAKOVLEV (*Izv. Moscow Selsk. Khaz. Inst. [Ann. Inst. Agron. Moscou]*, 8 (1902), No. 3, pp. 225-244).—The Norfolk, 3-course, and 18-course systems of crop rotation are under comparison. The 3-course and the Nor-

folk rotations represent extreme methods of extensive and intensive farming, respectively. The results indicate that by improved methods of cultivation the yields in the 3-course system may be increased 3 or even 4 fold.—P. FIREMAN.

Range improvement, J. J. THORNER (*Arizona Sta. Rpt. 1902*, pp. 261, 262).—A brief outline is given of the work in range improvement as carried on by the station.

Hanna barley, A. CSERHÁTI (*Zschr. Landw. Versuchsw. Oesterr.*, 5 (1902), No. 10, pp. 1141-1207).—Results of a series of cooperative variety and fertilizer experiments with Hanna barley in Hungary are given. It is concluded that this variety is the best for brewing purposes, and its wide and rapid distribution is regarded as bearing out this conclusion. The advantages of the variety consist in its early maturity and its greater productiveness and weight.

Experiments with cotton in 1902, G. P. FODDEN (*Jour. Khediv. Agr. Soc. and School Agr.*, 4 (1902), No. 6, pp. 216-229).—A report on fertilizer and rotation experiments with cotton, carried on at the experimental farms of the Khedivial Agricultural Society at Ghizeh and Mit-el-Diba in cooperation with many private farmers, is given, together with general directions for the culture of the crop. A comparison of commercial fertilizers with barnyard manure resulted in a marked financial benefit in favor of the barnyard manure. The use of superphosphate was found valuable, and the results of experiments favored the method of applying part of the total quantity before and the remainder after planting. Potash gave practically no increase in yield. An application approximating 400 lbs. of superphosphate and 100 lbs. each of nitrate of soda and sulphate of ammonia per acre gave the highest yield of cotton. In a rotation test cotton gave better results when grown after berseem than when following wheat.

Egyptian cotton, A. J. MCCLATCHIE (*Arizona Sta. Rpt. 1902*, pp. 251, 252).—In 1901 several varieties of Egyptian cotton were grown under irrigation. The yields per acre for the different varieties were as follows: Abbasi, seed cotton 1,580 lbs., lint 460 lbs.; Mitaffi, seed cotton 1,150 lbs., lint 275 lbs.; and Jannovich, seed cotton 500 lbs. The results thus far obtained indicate that Abbasi is the most profitable variety for the region and that it should be planted about the middle of March and given a moderate quantity of water with good cultivation.

Rotation and inoculation of leguminous crops, O. FROWERTH (*Zschr. Landw. Versuchsw. Oesterr.*, 5 (1902), No. 4, pp. 666-674).—The results of rotation experiments with leguminous crops are reported. Clover and lupines gave better yields when grown after some other leguminous crop than when grown on soil which had not produced a crop of that class for a series of years. The results with vetch in this respect were not so marked. On soil which had produced a leguminous crop the year before, lupines gave the highest yield as compared with clover and vetch. Similar returns were obtained from a soil which had produced a leguminous crop for 2 successive years prior to these tests. Lupines gave the highest yield of seed after clover and the smallest yield, with the highest yield of straw, after vetch. The best yields of green fodder from vetch were obtained when this crop was grown after clover, while clover itself was most productive after lupines. Small yields were obtained where lupines, vetch, and clover were grown after beans.

It was found that growing lupines, flat peas, and garden beans for 2 years in succession on the same soil was advantageous to the second crop. Vetch after vetch and clover after clover was not beneficial, but this is not believed to be entirely due to the rotation.

Inoculating soil with the special bacterium for each of the leguminous crops grown gave increased yields.

Studies on the potato, E. BRÉAL (*Ann. Agron.*, 28 (1902), No. 11, pp. 546-576, fig. 1).—This article reviews important work on the potato by different investigators and presents the results of the experiments conducted by the author.

The potato tuber contains approximately 16 per cent of starch and only 0.4 per cent of nitrogen. It is capable of retaining until spring 80 per cent of the moisture contained at the time of harvest. During winter storage respiration is active and water, carbon dioxid, and ammonia are given off. Chloroform vapor arrests the exhalation of carbon dioxid and when the tuber is exposed to it for a prolonged period the vital functions cease and a nitrogenous liquid exudes. When immersed in carbonic acid the tuber is asphyxiated and the solanin occurring principally in the cells, which have changed to a green color under action of light, is obtained. A low temperature decreases the respiration of the tuber and causes an accumulation of reducing sugar in its tissues. Freezing and subsequent thawing give rise to an exudation of an acid liquid containing solanin. In the tissues of the tuber ammoniacal salts are found, and the author demonstrated that nitric acid disappears when a solution of the salts is introduced into the parenchyma. The organic nitrogen of the potato exists partially in the form of a compound insoluble in water, and the other part, which is soluble, consists principally of albumin, coagulable at 70° C. After the albumin has been separated by this process the solanin is found in the remaining liquid.

In the spring the potato produces sprouts spontaneously, but water must reach its exterior to induce root growth at the base of these sprouts. The author observed that during germination large starch grains of the tuber are in process of breaking up and that small starch grains, presumably derived from the larger ones, are present in the sprouts. Green sprouts growing in water containing starch used this substance for food. The roots of sprouts took up ammonia, nitrates, and humic acid, causing an increase in the nitrogen content of the plant. All parts of the plant underground were found to contain nitrates.

Sprouts separated from the tuber were successfully grown in nutrient solutions and in rich soil kept moist with solutions containing plant food. The percentage of organic nitrogen in the dry matter of the young plants doubled in several weeks. The roots living in solutions took up nitric nitrogen until its supply was exhausted and then utilized the nitrogen present in ammoniacal form. The sprouts separated from the tuber and placed in rich soil accumulated large quantities of organic nitrogen and contained, after 5 months of growth, 460 times the quantity contained at planting time. The author calls attention to the fact that a crop of 40,000 kg. of potatoes per hectare, grown by A. Girard, took from the soil only 120 kg. of nitrogen, but concludes that the quantity contained in the stems, leaves, and roots of the plants must have been considerably larger.

Potash and phosphoric acid in the leaf ash of potato varieties rich in starch, J. SEISSL and E. GROSS (*Ztschr. Landw. Versuchsw. Oesterr.*, 5 (1902), No. 6, pp. 862-875).—The results of fertilizer experiments made in this connection showed that potash on the soils under test increased the yield of tubers and their starch content. The use of phosphoric acid alone affected the quantity and quality of the crop unfavorably. When the 2 elements were applied together, the detrimental effects of the phosphoric acid were decreased but not eliminated. The use of potash and phosphoric acid, alone or in combination, always increased the quantity of leaves and stems. Where phosphoric acid was applied, the foliage was of an abnormal color.

Ash determinations indicate that the content of potash and phosphoric acid was greater in the ash of leaves of varieties rich in starch than of varieties poor in that substance. This relation existed during the entire vegetative period and was not influenced by the application of fertilizers. The use of phosphoric acid as a fertilizer in most cases increased the content of this element in the ash of the leaves, while the application of potash had the opposite effect with reference to itself.

Variety tests with potatoes, E. S. BROWN (*Amer. Gard.*, 24 (1903), No. 424, pp. 86, 87).—A number of early and late varieties, some of which are new, were tested and the results are here reported, together with a brief description of the different varieties under experiment.

The pollination and fecundation of rye, K. ULRICH (*Inaug. Diss., Univ. Jena, 1902, pp. 63*).—The author reviews the studies of this subject by different investigators and reports the results of his own observations. He concludes that the rye blossom is self-sterile, although he found that self-pollination in a head or several heads of the same plant may cause a normal production of grains. In general, self-fertility is very rare and varies with the variety. Within the variety individual variations occur, so that completely sterile, as well as strongly self-fertile plants, are produced. The results, on the whole, indicate that every variety of rye must depend upon cross fertilization for a normal fecundation and grain production.

Saltbushes, J. J. THORNBUR (Arizona Sta. Rpt. 1902, pp. 262, 263).—A brief note on the work with saltbushes by the station.

Sugar beets, R. H. FORBES and W. W. SKINNER (Arizona Sta. Rpt. 1902, pp. 267, 268).—The results of analyses of Kleinwanzlebener sugar beets, grown in Salt River Valley in 1902, are given in a table. The average results of 18 samples show a sugar content in the beets of 15.7 per cent, with a purity of 81.7. The average yield per acre was 19.5 tons.

The sugar beet from an agricultural and industrial standpoint, L. GESCHWIND and E. SELLIER (*La betterave agricole et industrielle. Paris: Gauthier-Villars, 1902, pp. 668, figs. 129*).—Historical notes on the culture of sugar beets and the manufacture of beet sugar are given, and the production of sugar-beet seed and the general culture of the crop are discussed. The subject is further considered from a botanical and chemical standpoint, and remedies and preventive measures against insect enemies and plant diseases are suggested. The relation of sugar-beet culture to the sugar industry is considered at some length.

Fertilizer experiments with sugar beets, D. N. PRYANISHNIKOV (*Khozyaĭstvo, 1902, No. 13-14; rev. in Zhur. Opuĭtn. Agron. [Jour. Expt. Landw.], 3 (1902), No. 3, pp. 376-378*).—The results of fertilizer experiments with sugar beets in different localities were presented at the third congress of experiment station workers, which convened on the estate of P. I. Kharitonenko and was attended by 61 persons. The reports from the different regions showed that superphosphate has a very beneficial effect on the quantity and quality of the crop, and that this effect is increased when nitrate of soda is used in conjunction with the superphosphate. Although containing twice as much phosphoric acid, bone meal was inferior to superphosphate. The same was observed with Thomas slag.—P. FIREMAN.

Variation in the sugar content of swedes under different conditions of growth, S. H. COLLINS (*Jour. Soc. Chem. Ind., 21 (1902), No. 24, pp. 1513-1516, figs. 3*).—The methods of analysis are described and the results are presented in tables. Storing increased the sugar content from 6.30 to 6.94 per cent, or nearly one-tenth. This is ascribed to the loss of water by evaporation and the conversion of other constituents into sugar. The effect of the season is shown by a comparison of the average sugar content of the varieties grown, which was 6.26 per cent in 1900 and only 4.05 per cent in 1901. The richest varieties were Stirling Castle, X L All, Fell Bronze Top, and Arctic. It is concluded that under any reasonable conditions the effect of different manures on the sugar content is very small. The weight of sugar produced per acre was not always proportional to the weight of total crop.

Wheat culture and its profits in Central and Southwestern Russia, A. BORCHARDT (*Der Weizenbau im südwestlichen und zentralen Russland und seine Rentabilität. Berlin: Deut. Landw. Gesell., 1902, pp. 34*).—This is a report on the culture of wheat in central and southwestern Russia including a consideration of the economic conditions under which the industry exists.

Assimilation of plant food in wheat and rye, H. JUHLIN-DANNFELT (*K. Landt. Akad. Handl. Tidskr., 41 (1902), No. 2, pp. 134-136*).—Experiments with wheat and rye were conducted at Ultuna Agricultural College by A. Ulander at the suggestion of the author. The conclusions drawn from the results with reference to the ferti-

lizer requirements of the wheat plant at different stages of growth are at variance with those of Liebscher on this subject. In these experiments it was found that wheat which had formed hardly 2 per cent of the dry matter of the mature plant in the fall had, at this time, taken up only from 2.8 to 3.3 per cent of the nitrogen and potash and 7.3 per cent of the phosphoric acid given in the fertilizer application. From the beginning of June an energetic assimilation of the plant-food elements took place, the quantities of the different elements taken up being about equal. After blossoming, when the leaves begin to wither, assimilation decreases, and this is especially noticeable in the quantities of potash and lime used by the plant at this stage. Wheat requires abundant soil fertility for the production of large crops, but a good strong soil gives better results than the use of a heavy application of easily soluble fertilizers. Rye differs from wheat in that it takes up a comparatively large proportion of the necessary plant food in the fall. It is, therefore, more benefited by heavy applications of fertilizers than wheat and also because it is generally grown on poorer soils.—F. W. WOLL.

Production of economic plants in the Desert of Sahara, E. DÜRKOP (*Inaug. Diss., Univ. Jena, 1902, pp. 57*).—This dissertation contains a general description of the Desert of Sahara, together with more detailed discussions of the regions producing rubber, dates, senna, fibers, and colocynths.

Statistics of field crops (*Twelfth Census United States, Census Rpts., vol. 6 (Agriculture, pt. 2), pp. 7-275, 401-594*).—General statistical and historical summaries concerning the culture of the different crops are given with tables presenting the figures for the different States in detail. The following table is a summary of this information:

Acreage, quantity, and value of farm crops in the United States in 1899.

Crops.	Acres.	Quantity.				Value.
		Bushels.	Tons.	Bales.	Pounds.	
Corn	94,913,473	2,666,324,370	\$828,192,388
Wheat	52,588,574	658,534,252	369,945,320
Oats	29,539,698	943,389,375	217,098,584
Barley	4,470,196	119,634,877	41,631,762
Rye	2,054,292	25,568,625	12,290,540
Buckwheat	807,060	11,233,515	5,747,853
Broom corn	178,584	90,947,370	3,588,414
Rice	342,214	250,280,227	6,329,562
Kafir corn	266,513	5,169,113	1,367,040
Flaxseed	2,110,517	19,979,492	19,624,901
Clover seed	1,349,209	5,359,578
Grass seed	3,515,869	2,868,839
Hay and forage	61,691,069	84,010,915	484,254,703
Cotton seed	4,566,100	46,950,575
Cotton	24,275,101	9,534,707	323,758,171
Tobacco	1,101,460	868,112,865	56,987,902
Hemp	16,042	11,750,630	546,338
Hops	55,613	49,209,701	4,081,929
Peanuts	516,654	11,964,109	7,270,515
Peppermint	8,591	187,427	143,618
Dry beans	453,841	5,064,490	7,633,636
Castor beans	25,738	143,388	134,084
Dry peas	968,370	9,440,210	7,908,966
Sugar cane	386,986	4,202,202
Sorghum cane	293,152	291,703	815,019
Sugar beets	110,170	793,353	3,323,240

HORTICULTURE.

Problems in orchard pollination, G. O. GREENE (*Industrialist, 29 (1902), No. 11, pp. 163-178, figs. 5*).—The causes of failure of apple blossoms to set fruit are injured by drought; they may lack nourishment or receive an excess of certain

kinds of nourishment; the fruit buds may be injured from winter freezes or late spring frosts; and, finally, blossoms may fail to set fruit from improper pollination. The last factor was made the subject of special investigation during the season of 1902. Pollination experiments were made in the orchard of the Kansas Agricultural College with a large number of varieties of apples, beginning in most instances practically as soon as the pistillate parent was about three-fourths in bloom. The attempt was also made to use pollen from the staminate parent when the tree was in about the same condition. The results secured show considerable variation in the potency of the pollen of different varieties, both on their own pistils and on the pistils of other varieties. The proportion of fruit set to the number of flowers pollinated with pollen from the variety named was found with a few varieties to be as follows: Ben Davis, 25 per cent; Huntsman, $37\frac{1}{2}$ per cent; Cooper Early, $37\frac{1}{2}$ per cent; Grimes Golden, 29 per cent; Jonathan, $52\frac{1}{2}$ per cent; Smokehouse, $\frac{1}{2}$ per cent; Missouri Pippin, $33\frac{1}{2}$ per cent; Winesap, 30 per cent; Wine, 29 per cent. This list indicates Jonathan, Huntsman, and Cooper Early as valuable pollenizers for orchards. The data for Ben Davis, as well as for the other varieties, were obtained from 2 or more trees. One hundred blossoms of Ben Davis were covered and thus allowed to fertilize themselves. Out of this number 26 set fruit. This result is stated to differ from that of Waugh, who found Ben Davis self-sterile. The author states that the self-pollinated Ben Davis fruits were not so large nor so vigorous as those from cross fertilization. The experiments also showed that there was a greater tendency with the self-pollinated apples to fall from the tree before attaining the size of a hazel nut than with the cross-pollinated fruit. The potency of Jonathan, Cooper Early, and Huntsman was strongly brought out when these varieties were used to cross pollinate Grimes Golden, Arkansas Black, and Mammoth Black Twig. These latter varieties failed to set a single fruit outside the bags used to cover the cross-pollinated blossoms.

The variety Jonathan, while standing at the head as a pollenizer of other varieties, was not as potent on its own pistils as Cooper Early. The variety Kinnaird was found especially potent on its own pistils. Thirty-five blossoms of this variety were covered with papersacks before they opened and produced 35 well-formed fruits. These were but little smaller than the remainder of the fruits on the tree, which was loaded. The Kinnaird is a late-blooming variety and it is hoped that it may have considerable value as a pollenizer for Ralls and other late-blooming varieties.

Attention is called to the fact that varieties listed as shy bearers are those in which the selective power of the pistils is developed to the injury of the fruitfulness of the variety. Thus Jonathan, which is capable of fertilizing nearly every variety in the orchard, responds to but few varieties of pollen itself. Ben Davis, on the other hand, while of little value as a fertilizer for other varieties, responds to almost any variety of pollen.

In studying the agents of pollination, honeybees were found most useful. The bees work for the most part on the side of the tree away from the wind. With an east wind, 20 bees were counted on the west side of a Huntsman tree in full bloom and but 8 on the east side. With a south wind blowing at the rate of 7 or 8 miles per hour, 16 bees were found on the north side and 5 on the south side. Similar figures were obtained at other times with the Kinnaird variety. The bees worked in full sunshine in one case and in shade in another. So far as observed, the bees in every case chose the side of the tree most protected from the wind. Bees were noticed to visit the same flower 5 or 6 times within the course of 25 or 30 minutes. While the honeybee was found the greatest agent in pollination, enough other bees were present to insure a crop of fruit when the weather was favorable.

The extent to which the wind acts as an agent in distributing pollen was determined by exposing prepared microscopic slides at different distances from the tree and at different heights from the ground. The slides were exposed for varying periods of time and afterwards carefully examined to see how many pollen grains

had been caught. The results obtained indicate that the wind does aid in pollination though not to any great extent in the case of apples. Sometimes slides at considerable distances would be found to have caught more pollen grains than those nearer the tree. This was thought to be due to the fact that the pollen grains of the apple hold together to a certain extent and the farther they are blown from the tree the more likely they are to become separated by the wind.

A table is given showing the results of pollination obtained with a large number of varieties.

The need of a more systematic and natural classification of varieties than is offered by Thomas, Downing, or Warder is pointed out. The author found in studying the forms of blooms and the size and shape of the organs of the flowers that each variety possesses definite characteristics that might be used to distinguish it from other varieties. Modification of the pistil to insure pollination or prevent self-fertilization is a frequent characteristic. Thus the pistils of Grimes Golden were found to recurve outward to such an extent in some cases as to make self-pollination absolutely impossible. Ben Davis has a very straight, upright pistil, and Smokehouse a very large, knobbed pistil. "These modifications of pistils, the habits of the anthers in dehiscing, the shape, size, and color of the flower, the fruits and the definite characters of the lately introduced Russian varieties all offer a basis of scientific classification of the apple."

Self-sterility of orchard fruits, EWERT (*Proskauer Obstbau-Ztg.*, 7 (1902), No. 11, pp. 161-166).—The author's experiments showed that the apple Golden Pearmain is practically self-sterile, only one well-formed apple being obtained out of 48 pollinations made using pollen from the same tree. Ten good fruits were obtained from 27 pollinations when pollen from trees of other varieties were used. Notwithstanding these results, the author found that long lines of Golden Pearmain trees along highways from 300 to 350 meters from any other apple trees regularly produced good crops. His advice is that under German conditions, where villages are close together and many kinds of fruits are grown, mixing varieties in plantings is not necessary.

The sweating of apples, R. OTTO (*Proskauer Obstbau-Ztg.*, 7 (1902), No. 10, pp. 156-159).—The chemical changes that occur in apples during the sweating period were investigated by the author. In the first instance the apples were placed in a heap under a glass bell jar and examined from time to time thereafter. Under these conditions the sweating of the apples caused a loss in the water content and a corresponding increase in the dry matter. With somewhat immature apples the starch content decreased 4 per cent within 10 days and after 23 days had entirely disappeared. The sugar content increased, at the same time, from 9.98 to 11.51 per cent at the end of 23 days. With another lot of apples, somewhat riper, the starch content decreased 3.81 per cent after 17 days, while the sugar content rose from 10.10 to 11.53 per cent in the same time. With still riper fruit the starch content decreased 1.6 per cent in 14 days, while the total sugar content increased during the same period from 12.86 to 13.26 per cent. The acid content of the apples in all cases during the sweating period decreased from 10.26 per cent, in the first case mentioned above, to 8.27 per cent after 23 days, from 9.41 to 8.17 per cent after 17 days in the second case, and from 8.5 to 8.4 per cent in the third case after 14 days. The extract content also increased during the sweating period in all of the above cases.

In another experiment, where the apples were allowed to sweat in piles out of doors, as is usual in cider making, practically the same results were obtained. The results taken as a whole are therefore believed to show that the sweating of apples is advantageous in the manufacture of cider, since by this process the extract and sugar content of the apples can be increased within a comparatively short time. It is especially desirable with apples not yet fully ripe, since these contain comparatively large amounts of starch, which needs to be converted into sugar for the manufacture

of good cider. The apples must not be allowed to lie too long, however, after the starch has become converted into sugar. Fruit under a bell jar in the experiment mentioned above increased in sugar content from 9.98 to 11.51 per cent within 23 days; but after 49 days it had again decreased to 10.4 per cent.

Cold storage of fruit (*Canad. Hort.*, 25 (1902), No. 10, pp. 404, 405).—The results secured in the cold storage of fruit by Professors Hutt and Reynolds of the Ontario Agricultural College are reported as follows:

"Apples and pears keep best when wrapped singly in paper and packed in a shallow box not larger than a bushel. They ship best when, in addition, they are packed in layers and excelsior between. Apples keep better at a temperature of 31° than at a higher temperature. . . . Cold storage can not make bad fruit good; neither can it keep bad fruit from becoming worse. Only good specimens will keep for any length of time in cold storage and pay for the storage.

"For long storage it pays to select the best fruit and to pack it in the best manner known. The extra labor and the cost of material are more than repaid in the greater quantity and better quality of fruit left at the end of the storage period. With apples and pears at least, and, it seems likely, for most kinds of fruit, the fruit should be picked and stored in advance of dead ripeness. The maturing process goes on more slowly in cold storage than on the tree or bush."

Perfect specimens of medium sized apples and pears have been found to keep longer than the largest sizes picked at the same time. It is advised, therefore, that with pears and peaches the largest specimens be picked first and the smaller ones left to mature later.

"Fruit on being removed from cold storage should be allowed to warm gradually, and moisture should not be allowed to deposit upon it. But if the wetting can not be prevented, then the fruit should be spread out and dried as quickly as possible. With all kinds of fruit there is a time limit beyond which it is unprofitable to hold the fruit in cold storage or anywhere else. That limit, for sound fruit, is dead ripeness. Duchess pears can be kept profitably until late in December; Fameuse, or Snow, apples, until March or April. The time limit has to be determined for each kind of fruit."

The relation of color to the killing of peach buds by cold, J. C. WHITTEN (*Inaug. Diss., Univ. Halle, 1902, pp. 35, pl. 1*).—The author has investigated the winter temperature and the difference in the rate of transpiration of green and purple fruit buds and branches, and presents some data showing the value of whitewashing fruit trees to retard the swelling of the fruit buds and to maintain a more uniform tree temperature during the winter resting period. Part of the data relating to whitewashing peach trees in Missouri and the temperature of tree twigs have been previously noted (*E. S. R.*, 9, p. 835; 12, p. 643).

The author found that when the sun shone clearly in the morning whitewashed twigs did not warm up so rapidly as the surrounding air and only gradually reached that condition after noon. In sunshine, green and purple colored twigs reached a higher temperature than the surrounding air. When the sun was very bright the purple twigs were sometimes as much as 2° warmer than the green twigs. In one experiment on a sunshiny day in February the temperature in a purple colored twig was 10° C. When a black cloth was placed between the sun and the twig the temperature fell within 5 minutes to 5½° C. and rose again to 10° within 3 minutes after the cloth was removed. When twigs were blackened they absorbed slightly more heat than purple-colored twigs.

In order to determine the relative rate of transpiration of green and purple colored twigs, an equal weight of twigs of both colors was gathered and placed in a dry atmosphere in the laboratory in clear sunlight for 4 hours. At the end of that period the twigs were again weighed, when it was found that the purple-colored twigs had transpired fully twice as much water as the green-colored twigs. The experiment was repeated with large branches with practically the same results.

These experiments indicate that purple twigs on trees not only absorb more heat in sunshine, but also transpire a greater amount of water than green twigs and of course more than whitewashed twigs. Relative to the application of whitewash, the author states that it should be put on before the swelling of the buds begins. In Missouri peach buds one season began swelling in January. Toward the latter part of the resting period the buds start into growth much easier than earlier in the winter. The trees should be thoroughly whitewashed with 2 or more applications. The whitewash sticks better if made with 5 per cent skim milk.

The date-palm orchard, R. H. FORBES (*Arizona Sta. Rpt. 1902*, pp. 240-246).—The date-palm orchard now at the station comprises 556 trees, made up of 81 different varieties obtained from the Sahara, Egypt, Arabia, and Beluchistan. In addition there are 64 local 5-year-old seedlings. There are 327 suckers on the young trees, but it is thought that these can not be advantageously removed for 2 or 3 years. During the year 16 trees of the Rhars and 1 of the Deglet Noor varieties blossomed and produced a small crop of fruit. The date-palm scale has been brought under control by the use of hydrocyanic-acid gas fumigations.

Dates, A. J. McCLATCHIE (*Arizona Sta. Rpt. 1902*, p. 252).—Tests of date seed planted during the year indicate that these should be placed in the ground before the warm weather of spring, preferably some time between October and February. Late planted seed do not make as vigorous growth as seed planted earlier in the season. It has been found desirable in transplanting to keep a ball of earth around the roots and cut the leaves back to within a few inches of the ground.

Variety test of strawberries, O. M. TAYLOR (*New York State Sta. Bul. 218*, pp. 179-202, pl. 1).—Data are given showing the date of coming into bloom, date of first and last pickings, and total yield for 20-ft. rows of 56 varieties of strawberries. Most of the sorts grown were of quite recent introduction. Brief descriptions are given of all the varieties tested. A series of early spring frosts considerably reduced the yields of a number of varieties. The best yielding varieties were Crescent, Riehl No. 29, Monitor, Manokin, Beder Wood, Howard No. 2, and Riehl No. 26, ranking in the order named. Of these varieties, Riehl No. 29 produced too many light-colored and small berries to be highly recommended. The fruits of both Manokin and Howard No. 2 were too soft and of rather poor quality. Among the newer varieties thought worthy of trial are Bennett, Henry, Joe, Kansas, Monitor, Prof. Fisher, Riehl No. 26, Riehl No. 31, and Rough Rider. The largest early yields were given by Beder Wood and Crescent. Johnson Late was the latest variety to ripen, but lacks color and firmness. Prof. Fisher makes but few runners, and should therefore be planted closer than other varieties. Henry and Sample should be sprayed, since they are especially subject to leaf blight.

Strawberries in 1902, F. H. HALL and O. M. TAYLOR (*New York State Sta. Bul. 218*, popular ed., pp. 4, fig. 1).—A popular summary of the above bulletin.

Strawberries, A. J. McCLATCHIE (*Arizona Sta. Rpt. 1902*, pp. 253, 254).—The varieties Excelsior and Texas, both early varieties, have proved very satisfactory at the station, enduring the summer heat as well as any varieties ever tried there. It has been found that plants grown along shallow, open furrows do better than those grown on the sides of endless ditches. "Mulching with fine straw early in June has proved of value in enabling plants to endure the heat and drought of summer, especially during the first season after setting. Plants kept clean, and thus left exposed to the rays of the sun, make better growth than those where weeds are left to grow for shade."

New methods of grafting and budding vines, E. H. TWIGHT (*California Sta. Bul. 146*, pp. 13, figs. 10).—Details are given for making the green cleft graft, Horwath graft, Salgues graft, Besson graft, Clarac graft, Massable graft, and Vouzou graft. The author states that in vineyard work the Salgues graft is coming to be quite generally used. It is simple, forms a perfect union, and is of great value in reestablish-

ing vineyards on resistant stock. This graft consists essentially of fixing on a green shoot of the year an elliptic scion or shield carrying a bud at its center. In order that it be successfully used, it is necessary that the stock should be in full sap. In the Horwath graft the scion bud is inserted in the place of an eye of the stock. The Besson graft, which is a form of inlaying, has not been a success at the station when tried on green shoots. With ripe canes the results have been very satisfactory. The Vouzon graft is a Salgues graft made with an old scion bud. From 75 to 85 per cent of the grafts of this sort made at the station have commonly taken, and in one instance the success of 95 per cent was reported. "It is a simple graft and gives a perfect union. In case of failure, it is easy to repeat it the same season." The following directions are given for the selection of shoots bearing buds for scions:

"We should always choose branches growing from eyes which would have normally remained dormant till the following season, in preference to branches growing from buds bursting out normally. Shoots of medium or rather small diameter are to be preferred. These shoots will furnish the scion buds which are to be grafted on the old wood. The diameter of the shoot from which the scion bud is cut must always be a little smaller than the diameter of those upon which it is to be grafted. The best shoot is that developed in the shade; branches exposed to direct sunlight must always be rejected; the shoot should be light green in color, but not yellow. The petioles of the leaves of the shoot should be of a whitish-green color, even a little pinkish, slightly transparent at the point of junction with the limb. Shoots bearing leaves with deep green or reddish petioles should be rejected. The eyes of the extremity and base of the shoots, together with those placed at the base of the leaves having a very slender or very long petiole, should not be used."

In the preparation of scion buds, scions with half sapwood are considered far superior to scions with sapwood. In the station experiments the largest amount of budded wood was obtained when the shoots of the mother stocks were tied up in a V shape as soon as hard enough. The axillary buds and tendrils are removed at the time, and this operation is repeated 3 times during the season.

A study of grape pollen and what the results indicate, N. O. BOOTH (*Amer. Gard.*, 23 (1902), Nos. 414, pp. 767, 768; 415, pp. 784, 785).—Experiments were made during the summer of 1902 to determine, if possible, why certain varieties of grapes were self-sterile. The degree of self-fertility of 169 varieties of grapes has been previously noted (E. S. R., 11, p. 248). The work of the season has centered around two phases of the problem: (1) Whether the pollen on the self-sterile varieties might not be so scanty as to make self-fertilization impossible; and (2) whether lack of viability in the pollen itself might not be the cause of impotency on its own pistil as well as on all other varieties. As to the amount of pollen present, the investigations of the season showed that "there were greater variations on different clusters of the same vine than normally appeared on different vines of different varieties." The first and last clusters to bloom on the vine are usually not so well supplied with pollen as those blooming at the height of the season. In some cases the amount of pollen found was apparently insufficient to make pollination at all certain, but generally with most of the self-sterile sorts pollen was plentiful and apparently sufficient for pollinating purposes.

The viability of the pollen was studied by germinating the pollen grains in dilute sugar solutions. The percentage of sugar used varied in the different solutions from 1 to 20. The smallest percentage was found too weak in some instances, and most of the germination tests were made in 20 per cent solutions. With the self-fertile varieties germinations of the pollen varying from 4 to 95 per cent were obtained in these solutions, while with the self-sterile sorts the pollen did not germinate at all or made only a feeble growth, varying from 1 to 5 per cent. Besides these differences in germinating power of the pollen from self-sterile and self-fertile varieties, there was a difference in the behavior of the pollen which seemed to be quite constant. "The

self-fertile grains seem to be surrounded by a mucilaginous substance which makes them stick to one another more or less, so that the pollen, whether it lies dry on the slide or is placed in liquid media, arranges itself in a succession of clumps. This mucilaginous substance does not appear to be soluble in water, as the pollen grains retain their position even after several days in the solutions. The self-sterile pollen, on the other hand, shows no such arrangement, but the grains distribute themselves either on the slide or in the liquid like so much dry powder, quite by chance."

Microscopical examination of the pollen showed that with self-fertile varieties the dry pollen grains were oblong, blunt at the ends, and quite symmetrical. The pollen of the self-sterile sorts was more irregular, showing little of the symmetry of the other class. Varieties that were partly self-fertile had pollen grains of the two classes and intermediate forms. With these sorts the growths of pollen obtained in dilute sugar solutions were weak and had an unhealthy appearance. Experiments with large numbers of these varieties indicated that the "percentage of pollen which germinated did not vary widely from the percentage of self-fertile forms which the microscope showed that particular variety to contain." Pollen of the different varieties examined varied considerably in size, but there was no apparent connection found between the size of the pollen grains and their germinating power.

This lack of viability or potency of the pollen grains of self-sterile varieties is believed to be the main cause of self-sterility of grapes and sufficient in itself to account for this class of phenomena. The results obtained have an important economic value in choosing pollenizers for self-sterile grapes, since they give a method of selecting the best varieties for this purpose without waiting to make vineyard trials by sacking, etc., heretofore necessary. The sexual status of varieties can also be determined by this means within a single blossoming season.

The management of greenhouses, E. LONSDALE (*Pennsylvania Dept. Agr. Bul. 97, pp. 41*).—Practical advice is given regarding such matters as ventilation, watering, drainage, heating greenhouses, preparation of soil, control of insect pests and fungus diseases, propagation of plants, and annuals for winter blooming. In the introduction to the bulletin a rather extended account is given of the culture of American Beauty and some other roses.

Mature v. immature lily bulbs, A. F. WOODS (*Florists' Exchange, 14 (1902), No. 16, p. 462, fig. 1*).—Fifty healthy plants of *Lilium harrisi*, growing in one of the best bulb fields of Bermuda, were selected to test the relative value of mature and immature bulbs. Twenty-five of these plants were dug about the middle of May and the bulbs shipped to the United States where they were stored in a cool place. The remaining 25 plants were dug and shipped the latter part of July. At this time the tops of the plants were dead. Both lots of bulbs were planted in pots in August in the usual manner. The following winter the immature bulbs produced 64 per cent of badly diseased and worthless plants and 36 per cent of poor plants, averaging but $4\frac{1}{2}$ flowers each. The mature bulbs produced 68 per cent of good strong plants, averaging 7 flowers each, and 32 per cent showing some disease of the leaves, but even with these most of the flowers were all right. The plants were $\frac{1}{2}$ taller than those from immature bulbs. These results are believed to show clearly the great desirability of mature bulbs.

Statistics of horticultural products (*Twelfth Census United States, Census Rpts., vol. 6 (Agriculture, pt. 2), pp. 277-399, 595-795*).—Some of the general results secured in the U. S. Census of 1899-1900 on the production of certain vegetables, fruits, flowers, etc., are briefly noted below.

Vegetable culture.—In 1899, 5,753,191 acres or 2 per cent of the total area of the country devoted to crops was planted in vegetables. The vegetables grown had a total value of \$238,846,908, which is about 8.3 per cent of the total value of all farm crops. The average value of all farm products per acre was \$10.04, while for all

vegetables it was \$42.09. The potato was the most important vegetable grown. It occupied 51.1 per cent of the total acreage devoted to vegetables and was valued at \$98,387,614 or \$33.48 per acre. The production was 273,328,207 bu., an increase of about 25 per cent over the preceding decade. Sweet potatoes ranked second in value of the vegetables grown in the United States, the yield from the 537,447 acres grown being 42,526,696 bu. and the value per acre \$36.98. Next in acreage stood water-melons, sweet corn, and tomatoes, more than 197,000 acres being devoted to each crop.

Commercial gardening, that is, truck and market gardening, appears to have increased about 100 per cent at the North and fully 200 per cent at the South during the decade.

Canning industry.—The canning industry has grown rapidly and the annual output is now about double that of a decade ago. The pickles, preserves, and sauces put up in 1900 were valued at \$21,507,046, and the canned fruits and vegetables at \$56,668,313, of which the vegetables approximated but did not exceed one-half the total value. About two-thirds of the vegetables canned consist of corn and tomatoes. Peas stand next in importance. The number of cases of vegetables holding 24 cans each packed in 1899 was as follows: Tomatoes, 8,905,833; corn, 6,365,967; and peas, 2,738,251. Standard tomato cans hold 3 lbs. each and corn and pea cans 2 lbs. each. Maryland and New Jersey were the heaviest packers of tomatoes, New York and Illinois of corn, and Maryland and New York of peas. Considerable quantities of such other vegetables as asparagus, Lima beans, string beans, okra, pumpkin, squash, succotash, sweet potatoes, etc., are yearly put up in cans. The prices of canned goods have decreased about 25 per cent during the last decade.

Fruit culture.—The total value of all fruits produced in the United States in 1899 was \$131,423,517. Orchard fruits alone were valued at \$83,751,840; grapes, \$14,090,937; small fruits, \$25,030,877, and subtropical fruits, \$8,549,863. During the last decade orchard fruit production as a whole increased 15.4 per cent. Apples alone constituted 55 per cent of all orchard trees, peaches and nectarines 27.2 per cent, and plums and prunes 8.4 per cent. The total acreage of small fruits was 304,029, and the value of the product per acre \$82.33. Strawberries constituted about 50 per cent of the total acreage of small fruits. Raspberries stood next in importance.

The total value of all cultivated nuts was \$1,950,161. California alone reported 73.9 of this total. That State leads in the production of almonds and English walnuts. Texas leads in the production of pecans.

Floriculture.—In 1899 there were 30,417 farms reporting land under glass, representing a total of 96,230,420 sq. ft., or over 2,200 acres. Of this number 6,159 were commercial florists' establishments, having about 51,023,000 sq. ft. of land under glass. The total wholesale value of floricultural products was \$18,759,464, of which \$17,377,860 was for florists' products. The retail value, it is thought, could not have been less than \$30,000,000. The annual income from cut flowers alone is estimated at \$12,000,000 to \$14,000,000. The sale of cut roses is estimated at \$6,000,000, carnations \$4,000,000, violets—which stood third in importance—\$750,000, and chrysanthemums \$500,000. The annual production of roses and carnations is 100,000,000 each, violets 75,000,000. The average prices for roses and carnations is 20 to 25 per cent higher than 10 years previous, while violets, lilies of the valley, and tulips have considerably decreased in price.

Nursery industry.—Relative to the nursery business the twelfth census showed a total of 2,029 establishments, with 137,459 acres devoted to the growing of young trees. The value of the products from this area was \$9,231,503. New York leads in the production of nursery stock with a total of 237 establishments, yielding products valued at \$1,703,354. Other leading States in value of product are Iowa, \$636,543; Illinois, \$610,971; California, \$533,038; Ohio, \$538,534, and Pennsylvania, \$515,010.

FORESTRY.

Eucalypts, A. J. McCLATCHIE (*Arizona Sta. Rpt. 1902*, pp. 252, 253).—A brief account is given of experiments which have been conducted in the propagation and culture of various species of Eucalyptus. A heavy frost in December, following an unusually warm autumn, destroyed a number of species which had withstood previous low temperature. *Eucalyptus rostrata* was killed to the ground, but sent up sprouts the following spring. *E. salubris* and *E. corymocalyx* were killed entirely. *E. rudis*, *E. polyanthema*, and *E. leucorylon* were slightly, if at all, injured by the frost and also endured well the heat of Arizona summers. These 3 species have all proved adapted to the region, the first being the most desirable for general planting. The results of several years' experiments and observations upon Eucalyptus have been previously reported (*E. S. R.*, 14, p. 575).

Spontaneous groups of seedlings, A. C. FORBES (*Gard. Chron.*, 3. ser., 32 (1902), No. 829, pp. 351, 352).—The writer comments upon the tendency of different species of forest trees to reproduce themselves by natural seeding. With regard to conifers the only species that can be said to regenerate itself freely in England is the Scotch fir and then only after a clear cutting and under conditions which remove the seedlings from the shade and raw humus about the parent trees. In large pure forests the white pine and silver fir reproduce themselves to some extent, but neither the larch nor spruce show any inclination to spontaneously restock the ground. The author believes that the white pine would freely reproduce itself under shade, and prove to be one of the most valuable of introduced species, except for the inability of coniferous seedlings to push their way through a thick growth in these places where they are most likely to germinate. The most success in natural regeneration is to be expected with hardwoods, particularly the ash, beech, birch, oak, chestnut, etc. Of the heavier seeds, such as the beech, oak, and chestnut, it is necessary that they should get into the soil, and the simplest and one of the most effective methods of securing this is that of cutting a portion of the parent trees as soon after the fall of the seed as possible. The treading of the woodmen, removal of timber and brush, etc., force the seeds to enter the ground where they readily germinate. On heavy ground with little or no surface vegetation or humus this condition is almost indispensable. It is stated that young oaks appear in numbers only when coppice has been cut over during or following a year of abundant seed production. In the case of ash, birch, and sycamore the seed are more widely scattered and better adapted to getting worked into the soil before germination.

The future of our public forest lands, F. ROTH (*Forestry and Irrig.*, 8 (1902), No. 12, pp. 498-500).—This is a suggestion relating to the future policy regarding the control and management of the public forest lands, in which it is proposed that there be withdrawn from settlement, entry, sale, or other disposition all public lands which are more valuable for forest uses than for other purposes. The timber and other products upon such lands are to be protected and utilized according to economic principles.

Review of the lumber trade and forest interests of the South for 1902, D. W. BAIRD (*Tradesman*, 48 (1903), No. 9 (24. annual), pp. 130, 131).—The year 1902 is said to have been a highly prosperous one for the owners, handlers, and dealers of forest products in the Southern States, both in regard to the hardwoods and the pines. The production capacity in the hardwood sections has increased in the South in about the proportion that the timber supply of the northern section has decreased. Notes are given on the timber supply and the demand for different kinds of hardwoods, some of which are apparently increasing rapidly in favor with consumers. The general conditions of the Southern forest region are reviewed, and it is said that the heavy and constant drain upon the Southern forests has given rise to

fears in the minds of many that the period of final exhaustion is not far off. This serves to arouse an active interest in the matter and has caused the Government to take action which it is believed will result in the establishment of a forest reserve on the Appalachian mountain range which would not only preserve the timber but be valuable in other ways.

Forest conditions in southern Arizona, R. S. KELLOGG (*Forestry and Irrig.*, 8 (1902), No. 12, pp. 501-505, figs. 5).—In the mountain ranges of southern Arizona there are said to be at least 140,000 acres capable of sustaining coniferous forests. These forests are at elevations of from 9,000 to 10,000 ft., the precipitation below 7,000 ft. being insufficient for the growth of valuable species. The principal timber tree occurring in this region is the bull pine (*Pinus ponderosa*). This furnishes nearly all the sawed timber of the region, but associated with it are a number of other species of evergreen trees, it being entirely replaced in some places by the Engelmann spruce (*Picea engelmanni*) and the Alpine fir (*Abies lasiocarpa*). The best development of pine is always found on the northern exposures, and the greatest amount of timber in the Chiricahua Mountains, where an average of 5,000 ft. B. M. to the acre is estimated for at least 50,000 acres. The rate of growth of bull pine in southern Arizona is said to be quite rapid, and figures are given showing the average increment. Two forms of this pine are recognized by the lumbermen, but specifically they are said to be identical. The reproduction of this species is insufficient and unsatisfactory as a general thing, due to a number of factors which are briefly indicated.

The forests of Rhode Island, F. W. CARD (*Rhode Island Sta. Bul.* 88, pp. 39, pls. 8, figs. 18).—A general sketch is given of the subjects of forests and forestry, and a review of the present condition of the forests of Rhode Island. Referring to a statement, made in 1887 in a report of the Division of Forestry of this Department, to the effect that in a strict sense the forests had ceased to exist in Rhode Island, and that practically all the timber reported as cut in the State had been brought from other States, the author shows that in 1900 there were 33 sawmills in the State, which cut 18,265,000 ft. B. M. of white pine, chestnut, oak, ash, birch, maple, black walnut, and hickory lumber. This does not include the fire wood, which is produced in a considerable quantity within the State. The present forested areas are described, their characteristic species being mentioned, and descriptive lists are given of the more important forest trees which either occur or might be planted with a reasonable prospect of success.

Forestry in Germany, J. E. KEHL (*U. S. Consular Rpts.*, 71 (1903), No. 268, pp. 81, 82).—A brief account is given of the methods of forest management in Germany, and a statement given as to the area devoted to forestry. According to the imperial statistics for 1900, there were 34,569,926 acres in forest, an increase of 216,178 acres since 1883.

Forestry in Natal, J. S. LISTER (*Agr. Jour. and Min. Rec. [Natal]*, 5 (1902), No. 19, pp. 603-612).—As a preliminary to the reorganization of the forestry bureau of Natal, the author has made a survey and report to the authorities on the forests of that region. The extent and value of the forests of Natal and Zululand are indicated and suggestions given for their conservation and systematic exploitation. The author has found a number of exotic species of timber trees which have shown very remarkable growths, and suggests the more extensive planting of some of these.

Tree growing at high elevations in Ceylon (*Agr. Jour. and Min. Rec. [Natal]*, 5 (1902), No. 19, pp. 629-631).—A brief account is given of the rate of growth of various species of Eucalyptus, Acacia, bamboos, and ornamental and other trees at considerable elevations in the island of Ceylon.

Blue gums as forest trees, C. H. McNAUGHTON (*Agr. Jour. Cape Good Hope*, 21 (1902), No. 6, pp. 567-588).—An account is given of various plantations which have been made of the blue gum (*Eucalyptus globulus*) in the Midland Conservancy, Cape

Colony, the report being prefaced with an account of the climate, soils, rainfall, and winds of the region and comparisons drawn from other artificial plantations of this species. The tree readily reproduces itself from seed and is well adapted to coppice as well as standard growth. The blue gum was said to have been introduced in Europe probably as early as 1820 and since that time has been brought under cultivation in a number of localities. Tabular reports are given of the total and mean annual growth of this species in a number of regions, the annual increment varying from 273 to 696 cu. ft. per acre. After the general discussion of the subject an account is given of plantings in South Africa, one of which contains 20 acres and was planted at a cost of \$30.75 per acre. This includes the clearing and preparation of the land, together with the care of the trees until they are about 2 years old. The author estimates that plantings conducted at this rate would give a clear profit of about \$7 per acre if conducted by the government, or if funds could be borrowed at as low rate as 2½ per cent, which is readily secured by the government. The growth and acre increments are given, together with the data regarding the planting of 12 plantations which ranged from 3 to 12 years old.

Wood and cork. E. D'HUBERT (*Le bois et le liège. Paris: J. B. Baillière & Sons, 1902, pp. 96, figs. 31*).—A description is given of the anatomical, physical, and chemical characteristics of various kinds of timber, descriptions of the timber-producing species, the commercial production, conservation, and utilization of forest products, together with statistics of forest production.

SEEDS—WEEDS.

The influence of heat on the germination of seeds, H. H. DIXON (*Gard. Chron., 3. ser., 32 (1902), No. 821, p. 217*).—A brief account is given of a paper read before the botanical section of the British Association, in which the author's experiments on the resistance of seeds to high temperatures are described. As preliminary to the experiments the seeds were dried either over sulphuric acid or in ovens, the temperature of which was gradually raised to 90° C. After drying they were exposed for an hour or more to a higher temperature and then sown on moist sand. The seeds of the different varieties showed individual differences in their power of resisting high temperatures. A large percentage of oats would germinate after an exposure of from 100 to 105° C., while very few germinated if exposed to temperatures of 118° C. In general the higher the temperature to which the seeds were exposed, the longer would be the period of germination. Long exposure to comparatively low temperatures was found to be more fatal than a short exposure to a much higher one. Those seeds which germinated successfully after 1 hour's exposure at temperatures of 110 to 120° C., would not germinate at all if exposed for 12 days to temperatures of 95 to 97° C.

The germination of seeds after exposure to high temperatures, H. H. DIXON (*Notes Bot. School, Trinity Col., Dublin, 1902, No. 5, pp. 176-186*).—In continuation of experiments previously reported (*E. S. R., 13, p. 462*), the author has investigated the effect of high temperatures as influencing the germination of seed, and has been able to confirm the results previously obtained. Exposure of seed to high temperatures retards the germination, prolonging the period for a considerable time. In many cases the germination of seed in the experiments was abnormal, the most frequent abnormality being the protrusion of the cotyledons instead of the radicle from the seed. In many instances where the radicle emerged normally it was often abnormal in its subsequent behavior. Although many seeds were found able to withstand high temperatures for a comparatively short period, when subjected to moderately high temperatures for a prolonged time the germination was almost entirely destroyed.

Concerning the germination of leguminous seed and its influence by micro-organisms, L. HILTNER (*Arb. K. Gesundheitsamte, Biol. Abt.*, 3 (1902), No. 1, pp. 1-102, figs. 4).—After describing the structure and general characteristics of leguminous seed, some of the injuries to which this kind of seed is subject are discussed and their causes described. The effect of *Ascochyta pisi*, *Cephalothecium roseum*, *Penicillium*, and various bacteria on the viability of seed are discussed. The occurrence of hard seed in samples of leguminous seed is mentioned and the various methods practiced for securing their germination are described. The relation of soil organisms to leguminous seeds is discussed, and the effect of wounds upon the germination of seed, soaking, scratching seed coats, etc., are given in some detail. The predisposition of leguminous plants to certain root tubercle organisms is stated, and experiments are described in which seed inoculation and soil inoculation were compared. Conclusions are drawn for the information of agriculturists and gardeners.

The action of alcohol on germination of seeds, L. SUKATSCHEFF (*Bot. Centbl., Beihefte*, 12 (1902), pp. 137, 138; *abs. in Jour. Roy. Microsc. Soc.* [London], 1902, No. 5, p. 575).—The author reports that seeds of lupine and pea can remain for a considerable time in alcohol of various strengths without losing their capacity for germination. The wounding of seeds of yellow lupine and peppergrass, or the removal of the testa does not lead to as rapid a loss of germinative capacity as the results of some investigators tend to show.

Resistance of seeds to poisons, H. H. DIXON (*Notes Bot. School, Trinity Col., Dublin*, 1902, No. 5, pp. 187, 188).—In continuation of experiments previously reported (*E. S. R.*, 13, p. 462), a brief account is given of the resistance of seed to the influence of alcohol, corrosive sublimate, etc. The resistance of the seeds to these poisons is attributed to the imperviousness of their seed coats to the fluids in which they were immersed.

California grown sugar-beet seed (*Pacific Rural Press*, 65 (1903), No. 4, p. 52).—A brief account is given of tests of sugar-beet seed grown in California and subjected to the tests required by the German seed test regulations. The large seed, which numbered 41,493 to the kilogram, averaged 185 sprouts to each 100 seed balls. The small seed germinated only an average of 94 as compared with 130 sprouts to the 100 seed balls required by the above-mentioned regulations.

The Canada thistle and dandelion, L. H. PAMMEL (*Iowa Sta. Bul.* 61, pp. 143-148, figs. 5).—A description is given of the Canada thistle, which is regarded as one of the most noxious weeds of the State, and its distribution so far as represented by herbarium specimens is indicated. Various methods of extermination are described and a report given of attempts to combat this pest by spraying with dilute crude carbolic acid. This did not prove satisfactory, but when the dilute acid was injected about the root stocks they were killed for several inches below the ground. If this method be employed, following it up as the young thistles appear, the pest may be eradicated from lawns or similar regions where the area is not too extensive to permit of this method of treatment. The dandelion is also described as a troublesome weed, particularly in lawns, and the continued mowing of the lawn with occasional pulling up of the plants will after a while eradicate it.

Charlock or yellow weed (*Farmers' Gaz.*, 61 (1902), No 28, p. 493).—A brief report is given of experiments conducted on one of the council farms in Lancashire County, in which a crop of clover containing charlock was sprayed with 3 and 4 per cent solutions of copper sulphate, and 12 and 15 per cent iron sulphate at the rate of 50 gal. per acre. Where the 3 per cent sulphate of copper was applied, 2 sprayings being given, less than 1 per cent of the charlock set seed. A single spraying of sulphate of copper gave 9½ per cent and another 24½ per cent of seed-bearing plants. Two sprayings of copper sulphate gave 6 per cent of charlock seed, while 15 per cent spraying of iron sulphate, only 1 application being given, resulted in 47 per cent of charlock seed. The weight of the dried charlock plants was in nearly the same proportion in each case.

Destruction of charlock in grain crops, G. F. STRAWSON (*Farmers' Gaz.*, 61 (1902), No. 17, p. 309).—The author made a special effort to inquire into the operations of spraying for the destruction of charlock, and paid particular attention to the age of the plants when sprayed. He is convinced that many of the reported failures are due to the late application of the herbicides. If the application was made while the plants were in a rapidly growing, succulent condition, their destruction was effected by the use of a 3 per cent solution of sulphate of copper at the rate of 50 gal. per acre. Not only were the weeds destroyed but the general appearance of the grain crops was improved. The best results followed the use of large power sprayers, and the success of the operation was diminished in proportion to the delay which occurred after the charlock was in the most suitable condition for being destroyed. The suggested use of nitrate of soda in place of copper sulphate has not proved successful on extended trial.

Notes on the destruction of some injurious plants, G. HEUZÉ (*Journ. Agr. Prat.*, n. ser., 4 (1902), No. 33, pp. 211, 212).—Notes are given for the destruction of a number of troublesome perennial plants, among them the creeping bent grass, dog-tail grass, wild oats, Tussilago, bindweed, horse-tail rush, horse sorrel, etc. For those species which have perennial root stocks the author recommends fallowing, and early in the spring a thorough and deep harrowing over of the land, after which the root stocks are raked and burned. For the eradication of the Tussilago and the Equisetum, a thorough draining of the soil together with cultivation are suggested. The author recommends the application of fertilizers, particularly of calcareous ones, for combating the horse sorrel. Soils in which this plant grows abundantly are usually characterized by an acid condition which requires the application of lime for its correction.

DISEASES OF PLANTS.

Miscellaneous notes on fungus diseases of plants, L. H. PAMMEL (*Iowa Sta. Bul.* 61, pp. 139-142, fig. 1).—Notes are given on cowpea, clover, and asparagus rusts. The rust of the cowpea was first noticed during the fall of 1901, and numerous specimens were observed whose leaves were covered with brown rusty spots. An examination showed that the cause of the trouble was the fungus *Uromyces appendiculatus*, and so far as the author could ascertain this is the first recorded occurrence on this host. The fungus is rather common upon wild and cultivated beans, usually producing round spots which by confluence become irregular patches upon the leaves. The microscopic characters of the fungus are described and notes given upon its occurrence and distribution upon other host plants.

The clover rust, due to *U. trifolii*, was again noted abundant in 1901. In a previous publication (E. S. R., 3, p. 217) the author called attention to the occurrence of this fungus which was extremely common on second crop clover. It did not increase, and for a number of years was not abundant, but during the fall of 1901 it severely attacked the second crop of clover, causing no little injury to the plants.

Notes are given on the asparagus rust (*Puccinia asparagi*), which first made its appearance in Iowa during the season of 1901. Further information regarding the distribution of this fungus is requested, and the author suggests spraying the plants with a resin Bordeaux mixture, which is commonly recommended for this purpose.

Report of the vegetable pathologist and entomologist, H. TRYON (*Queensland Agr. Jour.*, 11 (1902), No. 6, pp. 403-408).—A summary report is given of the insects and fungi observed as injuriously affecting a number of plants during the year. The field work which was carried on by the author is described briefly, particular attention being given to investigations of banana diseases. These troubles seem to be due to a number of causes, among which are mentioned the punctures of minute thysanopterus insects which attack the fruits, a root disease caused by attacks of *Heterodera*

radicicola and also *Tylenchus* sp., an internal browning and gelatinization of the fruit probably due to the root disease, and a leaf disease which is accompanied by a specific fungus. These diseases will be subjects of further investigation and report. Preliminary investigations have also been begun on diseases of coffee and sugar cane.

The origin and propagation of cereal rusts through the seed, J. ERIKSSON (*Ann. Sci. Nat. Bot.*, 8. ser., 15 (1902), pp. 1-160, pls. 5, figs. 10; *abs. in Bot. Centrbl.*, 90 (1902), No. 6, pp. 146-150).—In continuation of his investigations on the cereal rust problem (*E. S. R.*, 11, p. 949), the author gives the results of experimental studies in rust propagation. In the previous paper he advanced the hypothesis of the possibility of infection through the seed, or the mycoplasma theory as it is called, and in the present account examples are given which are held to substantiate that claim. Methods were devised by which cereals were grown to maturity under what appears to have been perfect isolation. In numerous instances the plants were infected with rust even after all precautions had been taken to prevent external infection. In the second part of his paper the methods of propagation of rusts are discussed. It is claimed that cereal rusts can not be propagated either by an intercellular mycelium, as the presence of such a means has not been shown for most species of cereals, or by groups of spores on the surface or in the interior of the grain. It is further claimed that the uredo and teleutospores are not sufficiently abundant to habitually cause infection. Having disposed of these methods of infection the author claims the disease is to a large degree caused by the mycoplasma which exists in a symbiotic stage in the grain. Thus far it has been impossible to demonstrate the presence of this source of infection in its primary state, but it is believed that an intermediate form has been found which connects the invisible plasma and the mycelium of the rust. These are certain minute corpuscular bodies which float about in the protoplasm of the cell and later give rise to mycelium. The varying susceptibility of different varieties is held to be an argument in favor of the author's theory of rust propagation.

The nature of the infection is said to preclude the use of parasitic or fungicidal agencies for the prevention of rust. The treatment recommended is preventive, and the author advises the use of resistant varieties and the abandonment of the cultivation of all varieties which are notably subject to rust. He believes concerted studies should be made in all countries where cereals are injuriously affected by rusts, so that the effect of soils, exposure, fertilizers, etc., on rust may be ascertained, and attempts made to breed more resistant strains and varieties.

The recent literature relating to rusts is reviewed and a bibliography of the subject is appended.

The occurrence and distribution of cereal rusts through the seed, J. ERIKSSON (*Medd. K. Landtb. Akad. Exptlfält.*, No. 72, pp. 51, pls. 3, figs. 6).—This is a discussion of the mycoplasma theory relating to the origin and distribution of cereal rusts. The author recognizes the following species of Puccinia: *P. graminis*, the black rust, the æcidium of which occurs upon the barberry, with 6 specialized forms; *P. phlei-pratensis*, the timothy rust; *P. glumarum*, the yellow rust, with 5 specialized forms; *P. dispersa*, the brown rust of rye, the æcidium of which occurs on certain boraginaceous plants; *P. triticea*, the brown rust of wheat; *P. bromina*; *P. agropyrina*; *P. holcina*; *P. triseti*; *P. simplex*; *P. coronifera*, the crown rust, with 6 specialized forms, the æcidium of which occurs on species of Rhamnus; *P. coronata*, with 5 specialized forms; and an unnamed species of which 2 forms are recognized.—F. W. WOLL.

On the specialization of cereal rusts, J. ERIKSSON (*Medd. K. Landtb. Akad. Exptlfält.*, No. 73, pp. 25).—The results of the author's investigations on the specialization of cereal rusts to certain definite hosts are shown. The author considers specialization as an expression of inherent tendencies on the part of the rust toward producing new forms. This tendency is guided by the vegetative and climatic condi-

tions under which the parasite lives. Where a certain host plant is found abundantly and the climatic conditions are favorable to the growth of the fungus the parasite will reach a greater perfection as to its vitality and also a greater degree of systematic stability. On the other hand, if the supply of necessary host plant is limited and the fungus is near the limits of its natural habitat, its development becomes weaker and this weakness is expressed by less sharply defined differences and by a marked reduction in the ability of the fungus to attack new species of host plants.—F. W. WOLL.

The specialization of black rust of cereals in Sweden and other countries, J. ERIKSSON (*Centrbl. Bakt. u. Par.*, 2. Abt., 9 (1902), Nos. 16, pp. 590-607; 17-18, pp. 654-658).—A review is given of the previous investigations of the author on the specialization of cereal rusts, and the results of inoculation experiments with *Puccinia graminis* from the barberry upon 52 species of grass are described. Upon all of these species of grass the author was successful in securing infections. He is led to conclude that the phenomenon of rust specialization can no longer be attributed to internal, innate tendencies on the part of the rusts to produce new forms, but that it is due to the characteristics of the host plants and the influence of climate, etc., acting upon the parasite.

Cereal rusts, D. McALPINE (*Jour. Dept. Agr. Victoria*, 1 (1902), No. 4, pp. 425-431).—A general discussion is given of the nature of rusts and the losses due to them; and the results obtained in the experimental plots, in which varying susceptibility of varieties is shown, are given. The most injurious species of rust in Australia is that known as the summer rust (*Puccinia graminis*). Brief notes are also given on the barley and oat rusts (*P. simplex* and *P. graminis*).

Wheat and barley rusts, D. McALPINE (*Jour. Dept. Agr. Victoria*, 1 (1902), No. 5, p. 529, pl. 1).—Illustrated notes are given of *Puccinia graminis* occurring on barley and wheat, *P. triticea* on wheat, and *P. simplex* on barley.

Culture experiments with rust fungi, H. KLEBAHN (*Ztschr. Pflanzenkrankh.*, 12 (1902), Nos. 1-2, pp. 17-44; 3, pp. 132-151, figs. 5).—The result of extended culture experiments with a number of rust fungi is reported. Among those studied were species of *Melampsora* of willows and poplars which have their caecoma stage on *Allium*, those occurring on willows and *Galanthus*, on willows and *Ribes*, and studies of *Melampsora larici dulcinoides*, *M. pinitorqua*, *M. larici tremulae*, *M. rostrupii*, and *M. larici populinae*; also experiments with the leaf rusts of pine, the bark rusts of pine, various species of *Aecidium* and of *Puccinia*, together with species of *Gymnosporangium*.

A classification of the rusts of the Umbelliferae, C. B. PLOWRIGHT (*Gard. Chron.*, 3. ser., 32 (1902), No. 825, p. 282).—A brief account is given of the recent work of Lindroth on the classification of the Uredineae known to occur on various species of Umbelliferae. In this monograph descriptions are given of all the known species, which amount to nearly 90. The author has grouped the English species into 4 groups, based upon the proposed system of classification.

Rust of *Andropogon sorghum*, W. BUSSE (*Ber. Deut. Bot. Gesell.*, 20 (1902), No. 5, pp. 281-291, pl. 1; abs. in *Jour. Roy. Micros. Soc.* [London], 1902, No. 5, p. 592).—The author has studied the occurrence of this fungus in German East Africa, where it sometimes causes heavy losses in the crop of millet. He has arrived at the conclusion that the fungus is that described by Cooke as *Puccinia purpurea*. The technical characters are briefly described, and the writer states that this is the same rust as that known as sorghum rust in India, which has been attributed to *P. pennsili*.

Rust of timothy, J. ERIKSSON (*Öfvers K. Svenska Vetensk. Akad. Förhandl.*, 59 (1902), pp. 189-198; abs. in *Jour. Roy. Micros. Soc.* [London], 1902, No. 5, pp. 592, 593).—According to the author, the rust found on timothy is a separate and distinct species, and has been named *Puccinia phlei-pratensis*. Infection experiments have been tried by the author to trace the life history of the fungus, and after considerable difficulty the spermatogonia and aecidia were produced. The author is of the opinion

that the timothy rust was originally identical with *P. graminis*, but that it has become specialized on timothy and can only rarely be induced to grow on oats and rye.

The relation between host and parasite, H. MARSHALL WARD (*Ann. Bot.*, 16 (1902), pp. 233-315; *abs. in Jour. Roy. Micros. Soc.* [London], 1902, No. 5, p. 593).—A study has been made of the relation between the brome grasses and the rust *Puccinia dispersa* that occurs abundantly on the different species of *Bromus*. After a general introduction the different rusts that have been found on brome grasses are discussed and an account given of the efforts made to secure the proper sterilization of plants in rust infection experiments. The methods of infection and progress of the various experiments are given in detail. Pot plants were used, and the results obtained seem to differ for the different species of *Bromus*. Spores taken from one species would not infect others unless they were of closely allied forms. A comparison is drawn between the germination of the uredospores and that of pollen grains as observed in attempts at cross breeding, and the author believes it possible to grow species of grasses immune to rust infection.

Concerning pure cultures of the rust *Puccinia dispersa*, H. MARSHALL WARD (*Centbl. Bakt. u. Par.*, 2. Abt., 9 (1902), Nos. 5, pp. 161-168; 6-7, pp. 242-246, figs. 3).—During the course of a series of experiments on the relation between the host and parasite in the case of certain species of *Bromus* and the rust fungus *Puccinia dispersa* the author devised a simple method of obtaining pure cultures of both host and parasite which are described in detail. Inoculation experiments are described and, so far as the author's observations go, there does not seem to be any chance of infection through mycelium or other agencies within the seed. The only source of infection appears to be spores attached to the seed, as in none of his experiments was he able to discover any trace of mycelium within the seed.

A contribution to the study of cereal smuts and their prevention, C. von TUBEUF (*Arch. K. Gesundheitsamte, Biol. Abt.*, 2 (1902), No. 3, pp. 437-467, fig. 1).—Studies are reported in which, by inoculation experiments, it is shown that in the case of the stinking smut of wheat the fungus winters over as a mycelium in the young plants. So far as the oat smut is concerned, it does not appear to retain its vitality over winter in the soil. Winter oats treated with hot water and sown in infested soil were without any disease in the subsequent crop. Experiments are reported which seem to indicate that smut spores which have passed through the alimentary canal of animals retain their germinative ability to a considerable degree. Tables are given which apparently show marked differences in the susceptibility of varieties of wheat to smut diseases. The results of experiments with fungicides for the prevention of smut are reported in which seed treated with a copper-soda solution, wet and dusted with a copper-soda powder, and those treated with Bordeaux mixture gave crops nearly free from smut, while seed wet and rolled in superphosphate, copper sulphate and lime powder, and in kainit gave the worst infected crops. Negative results were obtained in experiments in which the effect of smut and rust on the health of animals was investigated by feeding the infected straw, grain, etc.

Experiments in the prevention of stinking smut of wheat, D. McALPINE (*Jour. Dept. Agr. Victoria*, 1 (1902), No. 4, pp. 413, 414).—The results of preliminary treating of the seed grain with copper sulphate, corrosive sublimate, and formalin are shown, the different treatments completely preventing the occurrence of diseased plants. In check plats which were otherwise treated in the same manner only 5 per cent of the plants were free from disease. The effect of the different treatments on the germination of the seed is shown, corrosive treatment being the least injurious, and copper sulphate the most so of the methods tested.

Some biological phenomena of *Ustilago maydis*, J. GRÜSS (*Ber. Deut. Bot. Gesell.*, 20 (1902), No. 4, pp. 212-220, pl. 1; *abs. in Jour. Roy. Micros. Soc.* [London], 1902, No. 5, pp. 591, 592).—When spore formation takes place in corn smut, the spore-

forming hyphae are said to become mucilaginous. The author has investigated this phenomenon in order to determine the possible presence of an enzym. He found an aminooxydase is present in the fungus similar to that which is found in the yeast of beer, and, as in the yeast, it is located in the vacuoles of the cells. As soon as the formation of mucilage begins in the smut, the production of oxydase is said to cease. The enzym is said to be most active when there is a maximum of metabolism in the cell, and the resting stage of the fungus follows the period of mucilaginous formation.

A new parasite of *Trifolium montanum*, F. BUBAK (*Centbl. Bakt. u. Par.*, 2. Abt., 8 (1902), No. 26, pp. 817-821; *abs. in Jour. Roy. Micros. Soc.* [London], 1902, No. 5, pp. 586, 587).—An account is given of *Urophlyctis bohemica*, which attacks plants of *Trifolium montanum*, causing them to be stunted in their growth and usually preventing their flowering. The leaves and petioles are covered with yellow spots and wart-like excrescences caused by the parasite. These warts are said to be much larger on the petioles than on the blade of the leaf.

The stem anthracnose of red clover, O. KIRCHNER (*Ztschr. Pflanzenkrankh.*, 12 (1902), No. 1-2, pp. 10-14, figs. 2).—In a previous publication (E. S. R., 14, p. 159) the occurrence of stem anthracnose of clover was mentioned and the cause attributed to *Glaeosporium trifolii*. Subsequent investigations of the author have shown that the disease in question is not due to that fungus but to an undescribed species to which he has given the name *G. caulivorum*, n. sp. The characteristics of the disease are given and the fungus is technically described.

Urophlyctis, a fungus causing galls on the roots of alfalfa, P. MAGNUS (*Ber. Deut. Bot. Gesell.*, 20 (1902), No. 5, pp. 291-296, pl. 1; *abs. in Jour. Roy. Micros. Soc.* [London], 1902, No. 5, p. 586).—Descriptions are given of galls produced on alfalfa roots which were hitherto ascribed to the presence of the fungus *Cladochytrium alfalfa*, but which the author believes belongs to the genus *Urophlyctis*. The galls occur as small excrescences on the larger roots. The disease occurs in damp soil only and is fatal to the plants. It was first described by Lagerheim from Ecuador, from where it has been recently brought to Alsace.

On the parasitism of *Pseudomonas destructans*, M. C. POTTER (*Proc. Roy. Soc. [London]*, 70 (1902), No. 464, pp. 392-397, figs. 2).—Since the publication of the author's paper on a bacterial disease of the turnip (E. S. R., 13, p. 467) his investigations have been continued, and the action of the cytase and toxin upon the living cells has been studied, and he has succeeded in tracing the passage of the bacteria through the cell walls into the cell. He has found that through the secretion of cytase and a toxin the parasitic action of the bacteria is comparable with that of certain parasitic fungi. In his previous investigations the attack of the organism could always be traced to a wound, and he has since found that the bacteria do not have the power to penetrate the cuticle of the mature epidermis. The parasite can, however, readily effect an entrance into its host through the undeveloped epidermis of young and tender structures. Whether in the case of *Pseudomonas destructans* the toxin or cytase is the first excretory product it is impossible to say, but the latter produces the first visible effect and is believed to prepare the way for the rapid action of the toxin.

The root rot of taro, J. G. SMITH (*Hawaii Sta. Bul.* 2, pp. 21, figs. 2).—An account is given of the causes and means for prevention of a destructive disease that threatens the extinction of the taro crop of Hawaii. The taro (*Colocasia antiquorum esculentum*) is one of the principal food plants of the native Hawaiian, and its long cultivation has apparently deteriorated the stock to a considerable extent. Wherever the taro is grown entirely under irrigation it suffers severely from the disease known as taro rot. This is characterized by the shortening and early maturing of the root stocks. It was found that the rot is readily spread by the planting of diseased suckers. It was also found that by planting suckers free from disease and securing a good circulation of irrigation water, together with the application of proper fertilizers and an occasional rotation of crop, this disease may be to a great extent prevented.

A disease of nursery stock, G. MASSEE (*Gard. Chron.*, 3. ser., 32 (1902), No. 822, p. 235, fig. 1).—The author reports having observed in widely separated parts of England a disease of young apple and plum trees which is due to the attack of the fungus *Botryella prunastri*. In instances cited more than 50 per cent of the entire stock was destroyed. Peach trees are subject to attacks of the same fungus, the disease on all showing well-marked characters which are easily recognized. The stem is the part attacked, and the first outward indication of disease is a slight browning of the bark which soon becomes hard, dry, and inseparable from the wood. There is no cracking or wrinkling of the surface and as a rule no further symptoms are evident during the first season of the attack. The mycelium, however, continues to grow inward, killing the cambium and young wood, thus preventing the upward flow of sap. The second season the leaf buds either do not expand at all or only imperfectly, and during the summer the branches die through a lack of food. The fungus does not appear to pass from the stem to the branches, the latter dying simply from starvation. The second year after the plant is attacked the tree is usually completely destroyed. At this time the infection of the fungus is indicated by the appearance in the dead bark of groups of minute transverse cracks which contain small clusters of the fruiting organs of the fungus. There is no appearance of anything like canker, and as the bark is not broken or disturbed in any way the superficial observer usually believes that the tree is killed by drought or some attack on the roots.

This fungus is common upon many species of rosaceous plants, and the spores produced on the wild plants usually start an epidemic of the disease in the nurseries. Although the infection sometimes takes place through punctures caused by insects, the epidemic occurrence of the disease can only be traced to infection taking place through the cut ends of twigs. The spores of the fungus mature from February to April, and it is recommended that no pruning should be done during this time. In the case of the young stem it is important that every wound made by pruning should be coated with tar or some substance that would prevent the germination of spores on the surface. Insects, especially aphids, should be held in check by means of insecticides, and wild trees in the neighborhood should be examined for the occurrence of the fungus.

Two unusual troubles of apple foliage, F. C. STEWART and H. J. EUSTACE (*New York State Sta. Bul.* 220, pp. 217-233, pls. 5).—During the summer of 1902 the attention of the authors was directed to a condition of apple trees over the greater portion of the State, the leaves being much wrinkled and distorted. Different varieties of apples seemed to be variously affected, the leaves being more or less covered with irregular blisters of various sizes caused by the separation of the lower epidermis from the mesophyll. It soon became evident that the blisters were in some way related to frost injury, and a review of the weather conditions showed that the spring of 1902 in New York was unusually wet and cool and there were a number of severe frosts occurring as late as May 10 and 11. Only the early leaves at the base of the shoots were affected and the most injury was observed where frosts were most severe.

The authors advance a theory for the injury which differs somewhat from that lately described by Sorauer. They claim that the leaves were frozen when only partially unfolded. The formation of ice crystals between the lower epidermis and the mesophyll caused these tissues to separate, and being removed from the source of nourishment the epidermis ceased growing while the parenchyma cells continued to expand. Not having an opportunity to spread laterally the leaf took the form of an arch, bringing about the wrinkled condition. In some cases the epidermis became ruptured and the parenchyma cells of the leaf exposed to the air died from excessive transpiration. This theory differs somewhat from that of Sorauer, who claims that the rupturing of the epidermis and death of the cells is due to the direct action of the frost.

This same phenomenon was observed on other plants, principally quince leaves, horse chestnut, cherry, etc.

Early in July apple growers in western New York became considerably alarmed at an extensive spotting, yellowing, and premature dropping of the apple leaves. A careful examination of many of the orchards showed that the trouble was primarily due to weather conditions and was greatly aggravated by spraying. Injury seemed to follow the use of all the insecticides used alone or in conjunction with Bordeaux mixture. Whether the Bordeaux mixture used alone was capable of causing the injury was not determined. The trouble was at its height about the middle of July, and by the end of the month in many orchards one-fourth to one-half the leaves had fallen from the trees. The affected leaves were more or less spotted, and late in August it was noticed that the majority of the spots were inhabited by a species of *Phyllosticta*, which subsequent investigations showed was closely related to *Phyllosticta pirina*. The parasitism of this fungus has never been proved by inoculation experiments, and the fact that Bordeaux mixture seems to have little effect in restricting the disease has led the authors to believe that it is not the real cause of the so-called leaf spot, but possibly the fungus is present as a saprophyte.

As a possible explanation of the injury, it is stated that when a shower is followed by bright sunshine, drops of water on the leaves act as lenses and concentrate the sun's rays to such an extent as to destroy the tissues beneath. This injury produces a condition similar to that recognized in leaf spots, and may possibly be preliminary to the presence of the fungus. In the authors' opinion a large part of the so-called apple-leaf spot is due to spray injury and weather conditions, and is not of fungus origin.

Spraying experiments in 1902 for black spot, D. McALPINE (*Jour. Dept. Agr. Victoria*, 1 (1902), No. 4, p. 432).—A brief report is given of experiments conducted for the prevention of apple scab by the use of Bordeaux mixture. The addition of linseed oil and sal ammoniac to Bordeaux mixture gave promising results.

Experiments in the treatment of apple and pear scab during 1901-2, D. McALPINE (*Jour. Dept. Agr. Victoria*, 1 (1902), No. 5, pp. 525-528, pls. 4).—The results of experiments for the prevention of black spot or scab of the apple and pear are given in detail. The relative susceptibility of different varieties is shown, and the effect of spraying with Bordeaux mixture for the prevention of this disease is indicated. The effect of a single spraying is shown by the largely increased proportion of marketable fruit, as well as the increase in the gross yield. Single applications of Bordeaux mixture made to pear trees just after the buds had opened resulted in the production of almost totally clean fruit of a variety which is ordinarily considered exceedingly subject to disease.

Experiments in the treatment of black spot of the apple and pear, D. McALPINE (*Jour. Dept. Agr. Victoria*, 1 (1902), No. 6, pp. 620-630, pls. 4).—An account is given of experiments conducted in a number of localities in Australia for the prevention of scab of apples and pears. The comparative value of Bordeaux mixture and copper-soda solution, potassium permanganate, copper acetate, and various modified formulæ of Bordeaux mixture is given. All of the treatments greatly reduced the amount of scab. The most successful fungicide used was that known as Grant's mixture. This is composed of Bordeaux mixture, to which some unknown ingredients are added.

The fungus causing black spot of the apple and pear, D. McALPINE (*Jour. Dept. Agr. Victoria*, 1 (1902), No. 7, pp. 703-708, pl. 1).—The black spot or scab of apple and pear is said to have been first observed in Australia in 1862. Since that time it has become well established throughout the country. Lists are given of varieties of apples and pears which are most subject to the attacks of the fungus, as well as those least affected. The symptoms of the disease and effects are indicated, and the life history of the fungus is briefly outlined.

Die-back of the apple, D. McALPINE (*Jour. Dept. Agr. Victoria*, 1 (1902), No. 6, p. 631).—The attention of the author has been called to a disease of apple trees known as die-back. Subsequent investigations have shown that in numerous cases the trees were attacked by an agaric (*Armillaria mellea*). The abundant presence of this mushroom has led to the conviction that it is the cause of the disease locally known as die-back.

Brown rot or ripe rot of fruit, D. McALPINE (*Jour. Dept. Agr. Victoria*, 1 (1902), No. 7, pp. 701, 702, pl. 1).—The effect of attacks of *Monilia fructigena* upon different fruits is shown, and for the prevention of the disease spraying with Bordeaux mixture is recommended. All diseased fruit should be collected and burned to prevent the spreading of the fungus spores.

Peach and plum rust, D. McALPINE (*Jour. Dept. Agr. Victoria*, 1 (1902), No. 6, pp. 617-619, pls. 2).—A description is given of the peach and plum rust (*Puccinia pruni*) in which the most susceptible varieties of host plants are mentioned and the application of Bordeaux mixture for its prevention is recommended.

Clasterosporium carpophilum and its relation to the gummosis of stone fruits, R. ADERHOLD (*Arb. K. Gesundheitsamte, Biol. Abt.*, 2 (1902), No. 5, pp. 515-559, pls. 2, figs. 6).—A description is given of the various forms of disease produced by *Clasterosporium* on stone fruit trees, and a detailed characterization of the fungus when grown in natural and artificial media is given. An historical statement regarding the fungus is presented, together with its synonymy and morphology, also the results of inoculation experiments. The relation of this fungus to the so-called gummosis or gum flow of stone fruits is discussed, and the conclusion is drawn from inoculation experiments that the *Clasterosporium* was the cause of the appearance of gum in all the experiments, and that the general conclusion is warranted that this fungus is a prominent cause of gum flow from wounds on stone fruit trees. A brief bibliography accompanies the paper.

Variations in the appendages of *Podosphaera oxycanthæ*, J. G. SANDERS (*Jour. Mycol.*, 8 (1902), No. 64, p. 170, fig. 1).—A brief note is given of variations in the appendages of the cherry powdery mildew, in which the branching of the majority of the appendages was noted.

A disease of pineapples (*Agr. News [Barbados]*, 1 (1902), No. 14, p. 213).—A brief account is given of a disease of pineapple plants in which the younger stages of the disease are characterized by the tips of the leaves turning yellow and drying up. As the disease progresses the discoloration of the leaves proceeds further until they are more or less wilted. The symptoms pointed to an insufficient water supply, and an examination of the roots showed in many cases that they were blackened and rotten. There was an unusual development of root hairs on the old roots, and the root hairs showed the presence of the threads of a fungus. It is believed that the extraordinary development of root hairs was caused by special effort on the part of the plant to replace those destroyed by the fungus. It is suggested that wherever this disease occurs all affected plants should be dug up and burned and the soil thoroughly limed.

On the occurrence and characteristics of black rot in Dagestan, N. N. VON SPESCHNEW (*Ztschr. Pflanzenkrank.*, 12 (1902), No. 1-2, p. 10).—The occurrence of black rot of grapes is reported in which the characters of the disease resemble those of the ordinary black rot to a considerable extent, but the fungus causing the disease is said to be *Diplodia uicola*, instead of the usual *Guignardia bidwellii* and *G. reniformis*.

An experiment on the treatment of gray rot of grapes, F. BOISSEAU (*Prog. Agr. et Vit.* (Éd. L'Est), 23 (1902), No. 47, pp. 601-603).—A brief account is given of spraying experiments in which fungicides containing potassium permanganate, alum, copper sulphate, and sulphur were tested. The best results were obtained with the alum fungicide, followed by that in which potassium permanganate at the rate of 125 gm. per hectoliter of water was used.

Powdery mildew and early pruning, L. RAVAZ (*Prog. Agr. et Vit. (Éd. L'Est)*, 23 (1902), No. 49, pp. 668, 669).—The value of early pruning of grapevines as a means for combating powdery mildew is mentioned and attention called to the fact that in order to be successful the affected shoots should be pruned while still carrying their leaves. Later pruning was shown by experiments to be without value.

Powdery mildew and early pruning, L. DEGRULLY (*Prog. Agr. et Vit. (Éd. L'Est)*, 23 (1902), No. 46, pp. 570, 571).—In an editorial note the author attests the efficacy of early pruning as a means of checking attacks of grape powdery mildew. It is recommended that grapevines be severely pruned early in the season following a destructive attack of the disease. This procedure will not obviate the use of fungicides, which should be applied later in the season.

Recent investigations in combating the plant and animal enemies of the grape, F. GVOZDENOVIC (*Separate from Allg. Wien. Ztg.*, 1902, pp. 20).—A brief account is given of experiments conducted in combating the grape downy and powdery mildews, whether occurring singly or simultaneously upon a plant, the grape anthracnose, and the leaf rollers.

Diseases of cultivated chrysanthemums, P. VOGLINO (*Malpighia*, 15 (1902), pp. 329-341, pl. 1; *abs. in Jour. Roy. Micros. Soc. [London]*, 1902, No. 5, p. 596).—An extended study has been made of the diseases of cultivated chrysanthemums, particular attention being given to one that has proved quite destructive to plants in Italy. The disease first appeared in July. In August and September there had not been much spread of the disease, but in the two following months it increased with great rapidity, killing many plants. The leaves were disfigured by irregular brown spots which gradually extended over the whole leaf surface. On these spots small pycnidia were formed by a fungus which the author called *Phoma chrysanthemi*. Specimens of *Phyllosticta leucanthemi* were occasionally found present, forming grayish spots, and at a later stage the *Phoma* was replaced by *Septoria chrysanthemi*, which continued to develop, and during the latter part of the season was the chief form of disease. By culture and infection experiments the author believes that the *Phoma* and *Septoria* are successive stages of the same fungus, and while the spores of the *Phoma* are short lived, the *Septoria* spores germinate after long intervals and are able to resist quite low temperatures.

Chlorosis in palms (*Gard. Chron.*, 3. ser., 32 (1902), No. 322, p. 232).—Attention is called to the rather frequent occurrence of yellow foliage in some palms, particularly Kentias. No very satisfactory explanation has been offered as a cause of this phenomenon, and as a possible explanation the writer refers to a recent announcement of Laurent in which he attributes the chlorotic condition to the fatty degeneration of the chlorophyll corpuscles. In healthy green leaves the chloroplasts are of a deep green color and there is no trace of the yellow bodies always present in cases of chlorosis. The inference is drawn that these yellow bodies result from degeneration of the chlorophyll. Some of the conditions for producing this state are said to be cultivation at low temperature with an excess of moisture, and growing plants from seed which have been gathered in an unripe condition, possibly from unhealthy plants.

Witches' brooms on the barberry, J. ERIKSSON (*Beitr. Biol. Pflanz. [Cohn]*, 8 (1903), pp. 3-127, pls. 3; *abs. in Jour. Roy. Micros. Soc. [London]*, 1902, No. 5, p. 592).—The author has shown by experiment that the abnormal branch development of the barberry is due to *Aecidium graveolens*, the Puccinia form of which is found on the tall oat grass. The region of attack is the central bud of the tender rosette of leaves. According to the author, the tissue entered by the fungus is not suppressed, but is excited to a quick, strong branch development followed by a condition of weakness which renders the abnormal branches unfit to resist the cold of winter, hence these parts are especially subject to winterkilling.

Larch and spruce fir canker, G. MASSEE (*Jour. Bd. Agr. [London]*, 9 (1902), No. 2, pp. 176-188, pls. 3).—A description is given of the larch canker due to *Dasy-*scapha calycina**, and a somewhat similar disease of the larch due to *D. resinaria*. The larch canker is due to a wound parasite, the investigations of the author not substantiating the claim of Carruthers that the fungus was actively parasitic. Out of more than 100 inoculations on unwounded branches of larch no infections were obtained, while spores applied to the wounded surface almost invariably established the disease. In nature the wounds are caused in various ways, as by wind or snow, the extrusion of sap due to late frosts, the biting and punctures of insects, particularly the larch aphid, and those made near the base of the stem in planting young trees. As a rule, when trees under 10 years of age are attacked, they are either killed outright or so deformed as to be of very inferior value. Older trees, while stunted to some extent, are not so severely injured.

The parasite causing the spruce canker is so nearly like that causing the disease just described as to be indistinguishable to the ordinary observer. The spruce is subject to infection in the same way as the larch. Seedlings and young trees should be protected with kerosene emulsion against the attacks of the larch aphid. As a safeguard against injury through late frosts, seed beds should not be placed in low-lying, damp localities, as these conditions are not only more subject to frosts but also favor the presence of the aphid. Recent investigations are said to show that the spruce-gall aphid (*Chermes abietis*) and the larch aphid (*C. laricis*) are alternate phases of the same insect. In the case of the attack upon large trees, the trunk will continue to grow and make wood for many years, but it furnishes a serious menace to surrounding trees by being a breeding place of the fungus.

Some new fungus parasites of oaks, E. HENRY (*Bul. Soc. Sci. Nancy*, 3. ser., 3 (1902), No. 2, pp. 99-103).—Descriptions are given of *Pseudoraulsa longipes*, *Aglaospora taleola*, and of *Pezizula cinnamomea*, all of which have been recently found occurring parasitically upon oak trees.

A twig blight of willows, C. VON TUBEUF (*Arb. K. Gesundheitsamte, Biol. Abt.*, 2 (1902), No. 5, pp. 567-570, pl. 1).—A twig blight of willows, due to *Fusicladium saliciperdatum*, is described. The disease seems to be common on many species of willow although so far as the author's investigations go it does not affect *Salix babylonica* or *S. pentandra*. For the control of this disease the author suggests a winter wash of a solution of copper sulphate followed by spraying with Bordeaux mixture in the spring after the appearance of the leaves.

Two new leaf parasites of deciduous trees, P. HENNINGS (*Ztschr. Pflanzenkrankh.*, 12 (1902), No. 1-2, pp. 14-16).—Descriptions are given of *Septoria caraganeae*, n. sp., which is parasitic on the leaves of *Caragana arborescens*, and of *Fusarium vogelii*, n. sp., which occurs on the leaves of the black locust.

Experiments in combating dry rot of timber, E. HENRY (*Bul. Soc. Sci. Nancy*, 3. ser., 3 (1902), No. 2, pp. 89-99).—A report is given of experiments which have been made in Austria, Russia, France, and particularly of those made in connection with the forest school at Nancy, on the preservation of timber against the dry-rot fungus (*Merulius lacrymans*) by injecting or otherwise treating with various chemicals.

A contribution to the knowledge of timber dry rot, C. VON TUBEUF (*Centbl. Bakt. u. Par.*, 2. Abt., 9 (1902), No. 3-4, pp. 127-135, fig. 1).—A number of experiments with cultures of the dry-rot fungus (*Merulius lacrymans*) are reported in which the efficiency of certain fungicides for preventing the spread of dry rot was tested. Copper solutions seemed to only slightly check the growth of the fungus and as Bordeaux mixture acted quite injuriously toward it the injury is attributed by the author to the lime and not the copper. Formaldehyde gas did not penetrate sufficiently to be of any particular service in destroying the fungus and it is not to be recommended for this purpose. It did, however, prevent the fungus spreading to other objects.

Spraying for fungus diseases, D. McALPINE (*Jour. Dept. Agr. Victoria*, 1 (1902), No. 7, pp. 709-714, pls. 2, figs. 2).—Directions are given for the preparation of Bor-

deaux mixture, copper-soda mixture, and copper sulphate and soft soap. For most purposes the Bordeaux mixture which consists of 6 lbs. of copper sulphate, 4 lbs. of lime, and 50 gal. of water is preferred. In order to increase the adhesiveness and spreading power of the fungicide good results have been obtained where 1 lb. of sal-ammoniac, saltpeter, or salt was added to every 50 gal. of Bordeaux mixture.

ENTOMOLOGY.

Insects notably injurious in 1902, F. L. WASHBURN (*Minnesota Sta. Bul.* 77, pp. 74, pls. 9, figs. 54).—Notes are given on the distribution of the Hessian fly in Minnesota. In combating this insect it is recommended that stubble be burned or plowed under and that screenings from thrashing machines should be fed or burned immediately. It is also recommended that wheat should not be planted on the same ground for 2 years in succession. The chinch bug is said to be distributed chiefly in the southern portion of the State. Attempts to destroy this insect in small experimental plots of wheat by sowing millet as a trap crop and by fumigation with bisulphid of carbon were unsuccessful. Spraying with kerosene emulsion killed a large percentage of the bugs. The use of parasitic fungi in killing chinch bugs has been abandoned on account of the inefficiency of this method. For preventing attacks of the insects the use of tar bands or furrows provided with post holes at regular intervals is recommended.

The chief grasshopper injuries during the year were due to *Melanoplus attanis*. A number of other species were somewhat injurious. The author recommends the passage of a law compelling all landowners to plow under all stubble found to contain grasshopper eggs. Large numbers of grasshoppers were destroyed by the use of hopperdozers. Notes are given on the methods of constructing these machines. Mention is made of a number of insect, bird, and other enemies of grasshoppers. The chief bird enemies in Minnesota are prairie chickens, hawks, blackbirds, crows, and meadow larks.

Attempts to prevent the attacks of horn fly by means of rancid lard were ineffective. Lard mixed with oil of pennyroyal, oil of Eucalyptus, or with pyrethrum or kerosene proved to be effective for 2 or 3 days. Fish oil is even more effective but is not recommended for dairy cows on account of its disagreeable odor.

Harpalus pennsylvanicus is reported as injuring strawberries. It is suggested that the beetles may be caught by means of lantern traps. Lawns were quite badly injured by *Lechnosterna rugosa*. For treatment of lawns, fumigation with bisulphid of carbon is recommended. This may be accomplished by means of a small air-tight box. Notes are also given on woolly aphis, alder blight, stalk borer, *Ligyrus gibbosus*, mosquitoes, cockroaches, carpet beetles, blister beetles, plum gouger, tarnished plant bug, melon aphis, corn louse, and New York weevil. Experiments with kerosene in combating mosquitoes were only partly successful. It was found that Phinotol oil in the proportion of 1 part to 12,000 parts of water killed the larvæ and pupæ of mosquitoes.

Notes on injurious insects, G. LÜSTNER (*Ber. K. Lehranst. Wein, Obst, u. Gartenbau, Geisenheim*, 1901, pp. 161-174, figs. 7).—The author calls attention to a number of observations which have been made on the subject of the influence of severe winters upon the numbers and multiplication of injurious insects. During the past few years *Zephus compressus* and *Blastodacna hellerella* have been unusually injurious to various fruit trees. *Boarmia gemmaria* is noted as an important enemy of grapevines, and notes are also given on *Calocampa exoleta* and on lantern traps for use in catching injurious insects.

Insects and their relation to agriculture, W. E. BRITTON (*Connecticut State Bul. Agr. Rpt.* 1901, pp. 193-207).—Brief notes on the damages caused by insects, on bene-

ficial insects of various kinds, and on San José scale, oyster-shell bark-louse, scurfy bark louse, codling moth, celery caterpillar, gypsy moth, maple borer, etc.

Some common insect pests of the farmer, H. T. FERNALD (*Pennsylvania Dept. Agr. Bul.* 99, pp. 32, figs. 8).—Notes on the habits, life history, and means of combating Hessian fly, wheat-stem maggot, army worm, wireworm, Angoumois grain moth, codling moth, apple-tree tent caterpillar, round-headed apple-tree borer, plum curculio, peach-tree borer, peach-twig borer, and plant lice.

Economic entomology, H. TRYON (*Queensland Agr. Jour.*, 11 (1902), No. 6, pp. 403-405).—Brief mention is made of insects injurious to apples and other deciduous fruits, citrus fruits, mango, grape, coffee, strawberry, potato, and other garden and field crops as well as ornamental and shade plants.

Economic entomology, C. FULLER (*Agr. Jour. and Min. Rec. [Natal]*, 5 (1902), No. 18, pp. 573-581).—The author discusses briefly the duties of economic entomologists and gives brief notes on some of the more important economic insects, including ticks, locusts, and corn worms.

Insect epidemics (*West Indian Bul.*, 3 (1902), No. 3, pp. 233-236).—Notes are given on the well-known frequent occurrence of certain insects in unusual numbers. Such an outbreak was recently observed in the West Indies in the sweet-potato worm (*Protoparce cingulata*). Notes are also given on the unusual outbreaks of other insects, with a brief account of the causes of these outbreaks.

Notes on the Ixodidae, L. G. NEUMANN (*Arch. Parasit.*, 6 (1902), No. 1, pp. 109-128, figs. 6).—A number of new species and genera of this family are described, including species of Ixodes, Rhipicephalus, and Haemaphysalis, as well as the new genus Ceratixodes. Descriptive and biological notes are also given on a number of other well-known species of this family.

The berseem worm, G. BONAPARTE (*Jour. Khediv. Agr. Soc. and School Agr.*, 4 (1902), No. 6, pp. 229-231).—*Agrotis segetum* attacks a number of farm crops in Egypt, including cotton, wheat, barley, maize, millet, potato, and berseem. The eggs are laid at very different seasons and there are at least 2 broods per year, 1 in spring and the other in autumn. The remedies suggested for controlling this insect are thorough cultivation of the soil, destruction of weeds, rolling the ground, flooding the berseem crop, and the application of gas lime.

The melon plant louse and the "manteca" disease, J. J. THORNER (*Arizona Sta. Rpt.* 1902, p. 264).—This insect is said to cause the manteca disease by excessive secretion of honeydew. Spraying, in order to be practical, should be done when the vines are small, before the whole field has become infested.

The codling moth and apple scab (*Gard. and Field*, 28 (1902), No. 14, pp. 157-168, figs. 16).—A general account of the codling moth and apple scab, partly compiled from American literature on these subjects and partly based on the experience of apple growers in Australia. The habits and life history of the codling moth are described in detail and notes are given on the methods which have proved most successful in combating this insect. The methods most strongly recommended are banding, training the trees low, and spraying with arsenicals.

Scale insects of the West Indies, H. MAXWELL-LEFROY (*West Indian Bul.*, 3 (1902), No. 3, pp. 240-270).—The author presents in this paper a list of the scale insects observed in the smaller West Indian islands. According to the author the islands may be classed, zoologically, into 3 groups—Greater Antilles, Lesser Antilles, and Trinidad and Tobago. Biological and economic notes are given on about 75 species observed in these islands.

Winter treatment and summer treatment of San José scale, J. DEARNNESS ET AL. (*Ontario Dept. Agr. Spec. Rpt.*, 1902, Oct. 28, pp. 4).—The commissioners inspected the work which had been done under the direction of Mr. Fisher in the destruction of the San José scale. It was found that summer treatment for the scale had prevented its increasing rapidly and spreading from tree to tree. The best results were

obtained from the use of kerosene emulsion containing 1 part of oil to 6 parts of water emulsified with whale-oil soap at the rate of $\frac{1}{2}$ lb. per gallon of oil. During experiments in winter treatment of the scale 6 forms of remedies were tried: Lime-sulphur-salt wash prepared according to 3 formulæ, kerosene emulsion, whale-oil soap, and hydrocyanic-acid gas. All of these remedies gave satisfactory results, but the best treatment was found to be the application of a lime-sulphur wash, in the proportion of 30 lbs. lime and 15 lbs. sulphur in water sufficient to make 30 gal.

Lime, salt, and sulphur wash, J. B. SMITH (*New Jersey State Bul.* 162, pp. 8, figs. 2).—The author presents a brief historical account of the use of California wash in the eastern States. Experiments conducted by fruit growers in New Jersey indicate that for moderately infested trees this remedy is as effective as any other which can be used. On some badly infested trees the wash did not prove as effective as could have been desired. The formula used in New Jersey is as follows: Lime 50 lbs., sulphur 50 lbs., salt 50 lbs., water 150 gal. It is recommended that the application be made in late winter or early spring before the trees have started to grow, and it is believed that there is no advantage in spraying twice a year.

The effect of carbon bisulphid upon scale insects, especially the San José scale, J. MORITZ (*Arb. K. Gesundheitsamte, Biol. Abt.*, 3 (1902), No. 2, pp. 130-137).—In this series of experiments the author made use of imported American apples which were infested with San José scale. The apples were fumigated in a zinc-lined chest. As a result of experiments with carbon bisulphid it was found that at temperatures varying from 15.4 to 21.5° C. this substance killed from 75 to 100 per cent of the scale insects and eggs when allowed to operate for from 2 hours and 5 minutes to 5 hours and 25 minutes, at a strength represented by 0.9 gm. to 2.3 gm. per liter of space. Observations made on infested apples indicated that San José scale might remain in a living condition for an indefinite period on apples maintained in storage at a temperature varying from 11.5 to 14.5° C.

Experiments concerning the effect of hydrocyanic-acid gas on scale insects, especially upon the San José scale, J. MORITZ (*Arb. K. Gesundheitsamte, Biol. Abt.*, 3 (1902), No. 2, pp. 138-147).—Experiments were conducted with hydrocyanic-acid gas upon a number of fruit trees received from Japan and upon American apples infested with San José scale. The fruit trees and apples were fumigated in a zinc-lined box containing 308 liters of space. It was found during these experiments that when 3 to 6 gm. of cyanid of potash was used and when the generated gas was allowed to operate for from 1 to 2 hours at different temperatures the treatment proved insufficient for destroying all of the San José scale. It is believed, therefore, that further experiments must be tried before the reliability of this treatment for destroying San José scale can be determined.

Instructions for the treatment of San José scale, W. M. SCOTT (*Georgia State Bd. Ent. Bul.* 5, pp. 12, fig. 1).—The author presents in a brief form the recommendations previously made (*E. S. R.*, 14, p. 589), together with certain additional suggestions. It was found that the California wash is exceedingly effective in destroying the San José scale, and that next to this remedy petroleum oils are most effective.

The Indian wax scale as an orchard pest, and its control, W. W. FROGGATT and W. J. ALLEN (*Agr. Gaz. New South Wales*, 13 (1902), No. 9, pp. 919-922, pl. 1).—Notes are given on the biology and economic relations of *Ceroplastes ceriferus* which attacks the blackthorn bushes of Australia, as well as persimmon trees and other economic trees. A number of fruit growers have been successful in destroying these scale lice by spraying with a solution of washing soda. When used in the proportion of $1\frac{1}{2}$ lbs. to 4 gal. of water the washing soda destroys the scale and causes no damage to the foliage. Experiments were also conducted for destroying this insect by fumigation with hydrocyanic-acid gas. Great success is reported from the use of this remedy. Some trees which were badly infested were apparently freed from the pest. Brief notes are also added on fumigation for red scale and other scale insects.

The limitations of parasites in the destruction of scale insects, W. W. FROGGATT (*Agr. Gaz. New South Wales*, 13 (1902), No. 11, pp. 1087-1093).—The author presents a general description of the value of the natural enemies of the scale insect. Attention is called to the controverted points concerning the importance of predaceous insects and fungus diseases in the destruction of injurious insects. The author believes that the effectiveness of parasites is limited in all cases and that only a minor significance can be ascribed to the natural enemies of scale insects in controlling the ravages of the latter.

The red spider of citrus trees, C. W. WOODWORTH (*California Sta. Bul.* 145, pp. 19, figs. 5).—Complaints having been received of injuries caused by red spiders on citrus trees, an investigation was made of this subject. It was found that the species concerned was *Tetranychus mytilaspidis*. Notes are given on the habits and life history of the mite and the species is described in detail in all its stages. The chief natural enemies of this mite are ladybirds, lace-winged flies, predaceous mites, a species of *Coniopteryx*, and a fungus disease. *Coniopteryx* appears to be the most important natural enemy of the red spider. It works entirely upon the egg of the mite, the larva being in constant search for the eggs of the red spider, which are punctured as soon as found. Experiments in combating the red spider indicate that fumigation is of no value; that sulphur is not as effective as it is for the red spider of deciduous trees; and that while spraying is a difficult operation and best done both from the inside and outside of orange trees, good results may be expected from the use of sulphid of potash. This material was prepared according to the following formula: Potash 32 lbs., sulphur 37 lbs., salt 2 lbs., water 50 gal. It was found that the red spider does not cause the spots on citrus fruits, as has been supposed, but injures the leaves, and when present in large numbers causes a dropping of the fruit.

The orange bark weevil (*Agr. News [Barbados]*, 1 (1902), No. 18, p. 280).—A species of *Cryptorhynchus* was found attacking orange trees in Granada and is believed to be present in other parts of the West Indies. A brief description of the insect in its different stages is given. The larvæ or pupæ may be killed in the bark with a knife, or the trunk of the trees may be painted with a preparation containing crude carbolic acid, whale-oil soap, and clay.

The mosquito blight of tea, H. H. MANN (*Planting Opinion*, 7 (1902), No. 50, pp. 847-851).—The insect which causes mosquito blight of tea in India is *Hellthyspe theivora*. It is a plant bug and the eggs are deposited in the green stalks or weeds. The insect passes the winter in both the adult and egg stages. The eggs are deposited in various positions, so that it seems impossible to control the species by severe pruning in early spring. Experiments in stimulating the growth of tea and in irrigating the plants for the purpose of controlling this insect were not very effective. The best results were obtained from applications of kerosene emulsion in the spring. The applications were made about 3 or 4 weeks before pruning.

The coffee borer in Usambara, F. STUHLMANN (*Ber. Land u. Forstw. Deutsch-Ostafrika*, 1 (1902), No. 2, pp. 154-161, pl. 1).—The insect discussed in this note is *Anthores leuconotus*. A brief account is given of the life history of the species and a description is presented of the insect in its different stages. It is suggested that remedial measures should include destruction of larvæ by burning infested trees, the capture of adult beetles, and the destruction of the young larvæ by poisoning the trunks.

Report on a trip to the region of Mkamba for the purpose of infecting grasshoppers with the grasshopper fungus, LOMMEL (*Ber. Land u. Forstw. Deutsch-Ostafrika*, 1 (1902), No. 2, pp. 176-181).—An extensive trip was made by the author for the purpose of locating swarms of grasshoppers and trying infection experiments by means of the grasshopper fungus. In many localities it was found impossible to practice this method with success. The information which was obtained from the natives regarding the depredations of grasshoppers and the direction taken

by swarms in their flight was in many instances unsatisfactory. In some cases the grasshoppers appeared to be killed off in large numbers by the fungus.

The guinea-grass moth (*West Indian Bul.*, 3 (1902), No. 3, pp. 238-240).—*Remigia repanda* is said to have caused severe injury to *Panicum maritimum*. Notes are given on the appearance of the insect in its different stages and on its life history.

The "green page" moth (*Cydimon leilus*) (*West Indian Bul.*, 3 (1902), No. 3, pp. 236-238).—Descriptive biological and economic notes are presented on this insect, which appeared in immense numbers in Trinidad during the autumn of 1901.

Notes and practical suggestions concerning recognition and methods of combating animals which are injurious to cultivated crops and fruits in the field and in storehouses, G. DEL GUERCIO (*Nuove Relaz. R. Staz. Ent. Agr.*, 1. ser., 1902, No. 4, pp. 497, figs. 284).—This publication is in the nature of a handbook of injurious insects, worms, crustaceans, etc. The following subjects are discussed: The value and practical importance of economic entomology; the various insecticides which are used and methods of preparing them; machines and apparatus used in combating insects and other noxious animals; worms injurious to cultivated plants, and mollusks which have been found to be of economic importance in agriculture. The main part of the publication is occupied with a detailed biological and economic account of the various species of mites and insects which injure cultivated plants in Italy.

Experiments concerning the effect of insecticides and fungicides upon plants treated with these substances, J. MORITZ (*Arch. K. Gesundheitsamte, Biol. Abt.*, 3 (1902), No. 2, pp. 103-129).—In the experiments reported in this article the author tested the effect of bisulphid of carbon and copper sulphate on plants. The experiments with bisulphid of carbon were made in a zinc-lined box of 1,201.5 cc. contents. The plants which were fumigated in this box included a number of flowers and weeds, and also certain trees, including apple, pear, cherry, plum, and conifers. Some of the plants were in pots and others were removed from the pots and freed from soil as far as possible. The results of these experiments are presented in detailed tabular form. It was found that at temperatures varying from 12.9 to 24.8° C. carbon bisulphid exercised no injurious effect upon plants which were exposed to it for a period varying from 30 minutes to 4 hours, at a strength represented by 14 to 71.8 gm. carbon bisulphid vaporized in a space containing 1,147 cc. On the other hand, all the fruit trees were killed by exposure for 24 hours at a temperature of 9.3 to 19.9° C. to a strength of carbon bisulphid represented by 150.2 to 162.2 gm. carbon bisulphid vaporized in a space containing 1,147 cc.

In experiments with copper sulphate a number of plants, including pear, plum, apple, and cherry, were dipped in solutions of this substance. The solutions contained from 0.5 to 1 per cent copper sulphate, and the temperature of the solutions was 14° C. The plants were immersed in the solution for from 2 to 3 hours. It was found that the apple trees bore this treatment best and that the pears and plums were most injured. The plants which were cut back before the treatment suffered more than those which were not thus mutilated.

A list of North American Lepidoptera and key to the literature of this order of insects, H. G. DYAR (*Smithson. Inst., U. S. Nat. Mus. Bul.* 52, 1902, pp. XLIX + 723).—In this bulletin the author presents a list of the known species of Lepidoptera of North America. The work is intended to replace Smith's List of Lepidoptera of Boreal North America, published in 1891. The classification adopted is based largely on the author's views, and synonyms are given in all cases, together with references to literature. The number of species listed is 8,622. An index of species, genera, and families is appended to the bulletin.

The origin of the natural coloration of the silk of Lepidoptera, D. LEVRAT and A. CONTE (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 17, pp. 700-702).—The authors sprinkled neutral red, methylene blue, and picric acid on the food of

Attacus orizaba and *Bombyx mori* in order to test the effect of these coloring matters upon the silk produced. It was found possible to influence the color of silk by the pigment matters used, the influence being exercised through the agency of the blood.

Observations on termites, or white ants, (I. D. HAVILAND (*Smithson. Inst. Rpt. 1901*, pp. 667, 678, pls. 4).—Notes are given on the anatomy, classification, and biology of various species of white ants, especially Malayan, South African, and Bornean species.

Mosquito development and hibernation, J. W. DUPREE and H. A. MORGAN (*Science*, n. ser., 16 (1902), No. 417, pp. 1036-1038).—Brief notes are given on the results of the authors' observations upon a number of species of mosquitoes. It is concluded from these observations that boat-shaped masses of eggs are not general, that the eggs of most species sink when the water is agitated, and that the eggs hatch when separated and shaken to the bottom. It was also found that the hatching of the eggs is irregular and may be postponed for a longer period as the result of the drying up of pools. The larval period may be much prolonged by insufficient food supply and low temperature. It is considered quite exceptional for any mosquitoes, including *Culex sollicitans*, to deposit eggs elsewhere than in water.

Observations on the Anopheles in the suburbs of Paris, EDMOND and ÉTIENNE SERGENT (*Ann. Inst. Pasteur*, 16 (1902), No. 12, pp. 940-949).—Notes are given on the species of *Anopheles* and other mosquitoes found in the vicinity of Paris. The habits and life history of these species are discussed. A reference is made to the natural enemies of the mosquitoes as determined by aquarium experiments and under natural conditions. Attention is called to the difficulty of determining the duration of the life of the larvæ and pupæ on account of the great variations due to different external conditions.

A study of Anopheles on the Isthmus of Suez, CAMBOULIU (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 17, pp. 704-706).—Brief descriptive and economic notes on 3 species of *Anopheles*, 2 of which are not named, while the third is *A. pharoensis*.

Beekeeping and the drought, A. GALE (*Agr. Gaz. New South Wales*, 13 (1902), No. 10, pp. 1036-1038).—On account of the unusual drought in New South Wales during the years 1901 and 1902, great difficulty was experienced in producing sufficient quantities of bee plants for a satisfactory honey yield. Brief notes are given on the extra care and precautions which may be required in preventing the development of disease among the weakened swarms.

Silk—its origin, culture, and manufacture (Florence, Mass.: *The Nonotuck Silk Co.*, 1902, pp. 53, figs. 38).—Brief notes are given on the discovery and introduction of silk, the culture of silkworms, and the reeling and other processes connected with the manufacture of silk.

Silk culture, G. MCCARTHY (*North Carolina Sta. Bul.* 181, pp. 54, figs. 15).—A revised form of an article already referred to from another source (*E. S. R.*, 13, p. 876).

Statistics of bees, honey, and wax (*Twelfth Census United States, Census Repts.*, vol. 6 (*Agriculture*, pt. 1), pp. CCXXXII-CCXXXVII).—Brief notes are given on the history of the introduction of bee raising into this country. According to the present census there are in the United States 4,109,626 swarms of bees, with a value of \$10,186,516. The total production of honey in 1900 was 61,196,160 lbs., of wax, 1,765,315 lbs., which together represented a value of \$6,664,904.

FOODS—NUTRITION.

The baking quality of flour and its estimation, G. HAMANN (*Inaug. Diss., Univ. Jena*, 1901, pp. 122).—Comparative studies of the different methods of estimating the baking quality of wheat flour are reported and a method proposed which depends on the fact that the nitrogenous material in different sorts of wheat varies

as regards its solubility in 70 per cent alcohol containing 1 per cent of acetic acid. Some of the conclusions which were drawn follow: The baking quality of wheat flour is determined by the gluten content, especially by the composition of the gluten. The physical characteristics of the gluten depend upon the relative proportions of its constituents. It appears that it is possible to show a definite relation between the power to absorb water and the baking quality of flour, but the quality is not shown by water absorption alone. There is no direct relation between the porosity of bread and the absorptive power of the flour. Chemical changes take place in the wheat berry and in wheat flour on storing. These depend on changes in the gluten, which apparently have a great effect upon the baking quality, though their nature is not understood. The total nitrogen content of flour ground from winter wheat grown under different conditions varies within wide limits.

The baking quality of wheat flour and its determination, G. HAMANN (*Die Backfähigkeit des Weizenmehles und ihre Bestimmung. Heidelberg: Carl Winter, 1902, pp. 120*).—A reprint of the above.

The relation between protein content and baking quality, R. REICHERT (*Inaug. Diss., Halle, 1902, pp. 72; Frühling's Landw. Ztg., 51 (1902), Nos. 16, pp. 565-579; 17, pp. 605-625; 18, pp. 645-660*).—Using flour from wheats containing different amounts of gluten, a number of baking experiments were made. The nitrogenous constituents of the flour and other milling products and of original wheat were studied by a modification of Fleurent's method, which is described. In some of the experiments separated gluten, glutenin, and gliadin were added to the flour in such a way as to modify the gluten content arbitrarily, and it was found that the baking qualities were correspondingly modified. One of the special objects of the investigation was to study the fitness of different sorts of flour for the manufacture of the small German breakfast rolls. The author compares his results with those obtained by other investigators and discusses the subject of bread making at length. Among the conclusions drawn were the following: The amount of bread produced by a given flour depends upon the amount of water which it will absorb. This is in turn dependent upon the total amount of gluten present. The increase in bulk during fermentation and baking of the dough—that is to say, the volume of bread produced—is determined by the absolute quality of gliadin present. The gliadin content of the flour can be very low and the flour still be such that the bread is not injured, 7 to 8 per cent being regarded as a maximum and 6 per cent as a minimum for good bread. If the gluten content is excessive, the bread becomes porous and the crust browns too quickly during baking. Skill in bread making has a great deal to do with the quality of the bread produced. The color of the interior of the baked product depends upon the color of the flour used.

The baking quality of flour and baking experiments with flour and gluten, H. SELNICK (*Ueber Backfähigkeit der Mehle und Back-Versuche von Mehl und Kleber. Leipzig, pp. 16*).—In this article, which is reprinted from the *Deutscher Müller*, the author discusses some of the earlier experiments which have to do with the baking quality of flour and briefly reports his own work on the subject, giving especial attention to a description of the Artopton, a form of apparatus which he has devised for use in determining the baking quality of flour.

Grain, flour, and bread, A. MAURIZIO (*Getreide, Mehl und Brot. Berlin: P. Parey, 1903, pp. XIII + 393, pls. 2, figs. 139*).—In this volume, which according to the author is designed as a laboratory handbook and for the special use of chemists, millers, bakers, botanists, and agriculturists, the botanical, chemical, and physical properties and the hygienic relations of grain, flour, and bread are discussed, as well as methods of judging and testing these characteristics. Milling, baking, and the other subjects included in the volume are exhaustively treated of, the results obtained by many investigators being cited, as well as data drawn from the author's own work.

Experiments on the baking qualities of wheat flour (*Deut. Landw. Presse*, 29 (1902), No. 91, p. 741, figs. 3).—A descriptive article based on A. Maurizio's experiments (p. 785).

Experiments with flour and grain, A. MAURIZIO (*Landw. Vers. Stat.*, 57 (1902), No. 5-6, pp. 405-417, pls. 2).—The distribution of gluten in grain is discussed on the basis of microscopical studies. The author also considers the absorption of odors and gases by flour and milling products, and reports determinations showing that 1,114 to 1,991 cc. gas were contained in a kilogram of flour. Directions are given for detecting the presence of *Acarus farinæ* in flour.

The Artopton, H. SELLNICK (*Das Artopton*. Leipzig-Plagwitz: E. Stephan [1902], pp. 16, figs. 7).—The author describes an apparatus which he has devised for use in determining the baking quality of flour. It consists of a flat plate over a water bath heated by a spirit flame and covered with a bell jar. On the plate the samples of dough are placed to rise, and may also be cooked.

Slimy bread, J. KÖNIG (*Fühling's Landw. Ztg.*, 51 (1902), No. 22, pp. 823-827).—The causes of slimy bread are discussed, and analyses reported which were made to show the changes in chemical composition of wheat bread due to the micro-organisms causing this condition. Results obtained with rye bread are also briefly noted. According to the author, micro-organisms convert some of the insoluble protein into soluble compounds, among which albuminose, peptones, amido compounds, and ammonia were recognized. That the cleavage goes so far that free nitrogen is produced is regarded as probable. Definite conclusions regarding fat were not drawn. A considerable proportion of the starch was rendered soluble, that is, it was converted into dextrin and sugar, which were further oxidized to carbon dioxide and water. Some acetic and lactic acids were also formed from carbohydrates. The pentosans underwent cleavage, but the crude fiber and the mineral matter were not affected. The slimy material, the author believes, is derived from the outer membrane of the bacteria themselves.

Fruits and fruit products: Chemical and microscopical examination, L. S. MUNSON, L. M. TOLMAN, and B. J. HOWARD (*U. S. Dept. Agr., Bureau of Chemistry Bul.* 66, pp. 114, pls. 12).—Analyses are reported of a number of samples of fresh fruits and of jams, jellies, canned fruits, and similar products made in the laboratory under known conditions, as well as commercial products gathered with the object of securing fairly representative samples. The analytical methods followed are described and discussed. The term "jam" is applied to all fruit products in which the pulped fruit is reduced to the consistency of jam, and thus includes what are often termed marmalades. It was found that the use of these terms varied considerably in different parts of the country.

Of the 96 samples of jams analyzed, 86 were commercial products and 10 were prepared in the laboratory. Eighteen samples of the commercial jams contained no glucose, 53 contained glucose but were not so labeled, and the remaining 15 were purchased as compound goods. Of the 58 samples of jelly analyzed, 44 were commercial products and 14 were prepared in the laboratory. Nineteen of the former contained no glucose, 13 contained glucose but were not so labeled, and the remaining 12 were purchased on the market as compound goods. Seventy-four samples of canned goods were examined, 39 samples of which were put up in glass, one in a stone jar, and the remainder in tin cans. The use of artificial coloring matter was found to be confined to fruits in glass. In discussing this class of goods the authors make the following statements:

"The customs of different firms differ so widely regarding the relative character of fruit packed in tin and glass that generalizations are difficult. It may be said, however, that the lowest grade of products is preserved in tin. Pie peaches, restaurant goods, and soaked goods (canned dried fruit) are prepared for a market that demands cheap products. It is necessary to choose the least expensive package available. In addition to this, the appearance of these articles would not be inviting in glass.

"In high-grade fruits, on the other hand, some canners place exactly the same products in glass and tin. Again, the expense of shipping bottled goods, both on account of breakage and freight rates, practically prohibits the preservation in glass of even high-grade goods that are to be shipped to a great distance, and many firms pack all their fruit in tin even for local markets. The average quality of tinned fruit is inferior to that preserved in bottles, and the lowest quality of the former is far below that of the latter."

Seven samples of brandied fruits and 3 of fruit butter were also analyzed, as well as 3 samples of solid marmalades, 2 of the latter being prickly pear products obtained in Mexico.

Letters are included in the bulletin which were received from a number of manufacturers in connection with many of the points discussed. The technique of the microscopical examination of fruits and fruit products is discussed and results of such examinations illustrated by a number of figures.

The manufacture of preserved foods and sweetmeats, A. HAUSNER (*London: Scott, Greenwood & Co., 1902, pp. VIII + 223, figs. 28*).—The causes of decomposition and fermentation are discussed, and different methods of preserving animal and vegetable foods are described in this volume, which is translated by A. Morris and H. Robson from the third German edition.

Preliminary report on the composition of cacao butter, J. KLIMONT (*Ber. Dcut. Chem. Gesell., 34 (1901), p. 2636; abs. in Ztschr. Untersuch. Nahr. u. Genussmit., 5 (1902), No. 23, p. 1164*).—A chemical study of the fats contained in cacao butter.

Milk powder in Germany, O. J. D. HUGHES (*U. S. Consular Rpts., 71 (1903), No. 268, p. 78*).—A brief note describing a milk powder of German origin. The composition is quoted.

New food materials, RÜHLE and J. KÖNIG (*Chem. Ztschr., 1 (1902), Nos. 6, pp. 152-154; 7, pp. 179, 180*).—The authors discuss the composition and nutritive value of proteid foods prepared from skimmed milk and other sources, meat extracts, predigested foods, and similar products.

A contribution to the chemistry of fatigue, H. W. HARPER and MARGARET HOLLIDAY (*Jour. Amer. Chem. Soc., 25 (1903), No. 1, pp. 33-47*).—A study of the phenomena of fatigue and breathlessness, apparently resembling the effects of caffeine in toxic doses, led the authors to investigate the metabolism of nitrogen and the renal excretion of phosphorus, sulphur, and chlorin when severe muscular work was performed. The subject was a healthy student, and the experiment was divided into 3 periods of 3 days each. During the middle period the subject performed excessive muscular work, which consisted of hurdle racing continued until he fell exhausted. The first and third were rest periods. The food and excretory products were examined.

The average amount of nitrogen consumed per day during the 3 periods was 17.06, 15.50, and 16.73 gm., respectively. The average daily outgo in the urine was 15.70, 16.25, and 15.17 gm., and the corresponding amounts excreted in the feces 0.99, 0.40, and 0.64 gm. Thus there was an average daily gain of 0.37 gm. during the first period of rest, an average daily loss of 1.15 gm. during the period of overexertion, and an average daily gain of 0.92 gm. during the final rest period. The authors studied the nitrogenous constituents of the urine as well as the chlorin, and the phosphoric and sulphuric anhydrides excreted during the different periods. The excretion of phosphoric anhydrid was greatest during the first period and least during the third period. The sulphuric anhydrid was greatest during the work period and least during the third period. The reverse was observed with chlorin.

The authors believe that their results show the presence of methyl derivatives of xanthin in the urine, due to the severe muscular work, but consider additional experiments necessary before deductions can be drawn. They propose, therefore, to continue the investigations.

Experiments on the metabolism of nitrogen, sulphur, and phosphorus in the human organism, H. C. SHERMAN (*U. S. Dept. Agr., Office of Experiment Stations Bul. 121, pp. 47, dym. 3*).—The digestibility of a simple mixed diet, and the income and outgo of nitrogen, sulphur, and phosphorus were studied in 10 experiments of which the author was the subject. The comparative digestibility of liberal and restricted diet and the effects of loss of sleep were also studied. The diet consisted of bread (crackers) and milk, with butter added in some of the tests. The author regards additional experiments necessary before final deductions can be drawn, but summarizes the principal results as follows:

"The proportions of protein digested from a restricted diet were about 0.7 per cent higher than those digested from a liberal diet of the same composition.

"Marked loss of sleep for 3 successive nights resulted in a small increase in the amounts of nitrogen, sulphur, and phosphorus excreted. The increase of sulphur was proportional to that of nitrogen, and the increase of phosphorus was very slightly larger, the relative difference being no greater than might be attributed to the usual daily variations. The increased elimination resulting from loss of sleep did not appear until the third day, while changes resulting from alteration of the diet were always perceptible on the first day.

"The data collected regarding the relative 'lag' of nitrogen, sulphur, and phosphorus are not yet sufficient to permit general conclusions to be drawn.

"In general the metabolism and 'balance' of sulphur ran approximately parallel with that of nitrogen. The renal elimination and 'balance' of phosphorus showed fluctuations similar to those of nitrogen, but not so closely parallel as in the case of sulphur. The elimination of phosphorus by the intestine was large and variable, making the accurate separation of the feces an important factor in the determination of the phosphorus balance."

The results attending the use of a diet sufficient for maintenance but poor in protein, B. H. JÄGERROOS (*Skand. Arch. Physiol., 13 (1902), No. 6, pp. 375-418*).—The author reports experiments with dogs in which the animals lived for a number of months on a diet furnishing as low as 0.2 gm. nitrogen per kilogram body weight and finally died from some infectious disease. The balance of income and outgo of nitrogen was determined. The diet after a time was not relished and the dogs with difficulty could be induced to eat it, which in the author's opinion showed that it was not satisfactory. He holds that if a daily diet fulfills hygienic requirements, is sufficiently abundant, palatable, easily digested, composed of fresh materials, and of suitable volume, no special attention need be paid to the protein content, as a sufficient amount will undoubtedly be furnished.

The excretion of carbon dioxide and water by man through the skin, E. A. VON WILLEBRAND (*Skand. Arch. Physiol., 13 (1902), No. 6, pp. 337-358, figs. 3*).—In the experiments reported the body of the subject was inclosed in a metallic box or chamber, the head protruding through the top. There were devices for drawing a current of air through this chamber and collecting and analyzing it, the apparatus and methods being described. From the author's experiments he concluded that the excretion of water through the skin during absolute rest is moderate and is proportional to the temperature of the surrounding air, increasing from 12° C. to the point at which the temperature is great enough to cause perspiration. An abundant secretion of perspiration is observed between 30 and 33° C. The amount of carbon dioxide excreted through the skin remains constant at a temperature of from 20 to 33° C., during absolute rest being equal to 7 or 8 gm. in 24 hours. If the temperature rises to such a point that perspiration is induced, the amount of carbon dioxide increases suddenly to 3 or 4 times its former value. The author's investigations do not show how carbon dioxide is excreted through the skin, but he offers the suggestion that some of this gas, which is present in the blood, reaches the surface of the body by diffusion. He discusses also the source of the water excreted as perspiration.

Does the diet have an effect upon the excretion of carbon dioxide when muscular work is performed? J. E. JOHANSSON and G. KORÆN (*Skand. Arch. Physiol.*, 13 (1902), No. 3-5, pp. 251-268).—Continuing the experiments noted above, the authors studied the effect of diet upon muscular work as shown by changes in the respiratory quotient. Some of the principal conclusions which were drawn follow: The results of these experiments, showing a decreased amount of carbon dioxide excretion during muscular work as a consequence of the diminished glycogen content of the body, indicate that when fat is a source of muscular energy it is not first converted into carbohydrates, as has been suggested. The carbon dioxide excreted during work and rest, when sugar, protein, and fat were consumed and also after fasting, was greater than the amount when work was performed and the glycogen in the body had been exhausted by fasting and muscular work. The authors note that sugar or protein added to the diet affected the excretion of carbon dioxide in a manner entirely different from what would be expected from the amount of muscular work. This phase of the subject is discussed. According to the authors, when the glycogen of the body is exhausted, muscular exertion and internal muscular work increase the cleavage of body fat. From the experiments it appears possible to maintain at a constant height for a number of hours the increased carbon dioxide excretion caused by consuming nutrients, provided the nutritive material is taken repeatedly in small portions. These and other deductions are discussed at length.

The work of the digestive glands, J. P. PAWLOW, trans. by W. H. THOMPSON (*London: Charles Griffin & Co., 1902, pp. 208; rev. in British Med. Jour., 1903, No. 2194, pp. 151-153*).—This volume summarizes the author's experiments on the physiology of digestion.

Pancreatic secretion, BAYLISS and STARLING (*Jour. Physiol.*, 1902, Sept.; *abs. in British Med. Jour.*, 1902, No. 2191, *Epid.*, p. 96).—The occurrence of a body called "secretin" is noted, which the authors state is secreted in the epithelium of the small intestines and is carried by the blood to the pancreas, where it causes a flow of pancreatic juice. The investigations reported are a contribution to the subject of the physiology and pathology of pancreatic secretion and digestion.

Concerning the utilization of glycerin in the body and its estimation in urine, H. LEO (*Arch. Physiol. [Pflüger]*, 93 (1902), No. 5-6, pp. 269-276).—In the experiments described a man consumed from 8.93 to 26.76 gm. glycerin per day and no disturbance of metabolic processes or of digestion was observed. When larger amounts of glycerin were consumed a portion was excreted in the urine. This was not the case with the smaller doses. According to the author 0.29 gm. glycerin per kilogram of body weight is retained in the body. Reasons are given for believing that the glycerin retained in the body does not come from the cleavage of fats. Analytical methods are described.

Calculating the cost and nutritive value of army diet, SCHUMBERG (*Deut. Mil. Ärtz. Ztschr.*, 1901, No. 8-9, p. 522; *abs. in Hyg. Rundschau*, 12 (1902), No. 22, p. 1172).—The subject is discussed and a dietary standard proposed, which is based on an estimated energy requirement of 3,000 calories per man per day, of which 400 calories are to be supplied by protein and 500 by fat.

General mess manual and cookbook for use on board vessels of the United States Navy (*Washington: U. S. Navy Dept., 1902, pp. 32*).—In this publication, which was prepared under the direction of the Paymaster-General of the U. S. Navy Department, the organization and administration of the general mess of the Navy is discussed, as well as the establishment and administration of commissary stores, and related topics. A number of recipes are given for the preparation of the food served the enlisted men in the Navy.

Home science cookbook, MARY J. LINCOLN and ANNA BARROWS (*Boston: Home Science Pub. Co., 1902, pp. X+281*).—A large number of recipes are given for dishes suitable for different meals. The value of the various classes of foods is discussed, and menus suggested for each month of the year.

International catalogue of scientific literature. Q—Physiology (*Internat. Cat. Sci. Lit.*, 3 (1902), pt. I, pp. XIII+404).—The literature indexed in this volume, which is part 1 of the physiology volume for 1901, comprises general physiology, physiological chemistry, including foods, the physiology of the different systems, pharmacology, experimental psychology and pathology, and related topics. The volume corresponds in character to those for chemistry and botany already noted (E. S. R., 14, pp. 632, 637). W. A. Osborne is referee.

ANIMAL PRODUCTION.

Forage crops, R. H. FORBES and W. W. SKINNER (*Arizona Sta. Rpt. 1902*, pp. 268-270).—Analyses are reported of bran, Egyptian corn (leaves, stalks, and grain), almond hulls, native saltbushes (*Atriplex nuttallii* and *A. lentiformis*), wheat hay, and alfalfa hay. A number of these follow:

Composition of a number of feeding stuffs.

Samples.	Water.	Protein.	Ether extract.	Nitrogen-free extract.	Crude fiber.	Ash.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Egyptian corn:						
Leaves.....	6.15	10.06	1.72	46.45	23.81	11.81
Stalk.....	6.00	3.69	3.43	47.78	31.61	7.49
Grain.....	8.21	13.13	4.79	70.47	1.61	1.79
Saltbush, <i>A. nuttallii</i>	5.20	11.69	2.16	51.02	20.55	9.38
Saltbush, <i>A. lentiformis</i>	6.11	7.81	1.99	52.31	27.05	4.73
Almond hulls.....	4.81	5.50	3.23	60.33	17.33	8.80

The almond hulls or pericarps, which are discarded in preparing almonds for the market are sometimes used as fuel. According to the authors, it has been observed that horses will learn to eat them and they are apparently a fattening feed.

"The analysis shows this material to be rich in nitrogen-free extract, which includes sugar, starch, and other carbohydrate foods, while poor in protein. It would doubtless be good economy in the occasional instances where almond hulls are available, to teach farm stock to consume this novel though valuable food, due regard, however, being had to the presence, as shown in our sample of 7.34 per cent of tannin in the air-dry material. Tannin in large amount is stated to be an intestinal irritant, making caution advisable in using a foodstuff of this nature."

Inspection of feeding stuffs, W. H. JORDAN, C. G. JENTER, and F. D. FULLER (*New York State Sta. Bul. 217*, pp. 187).—Analyses made under the provisions of the State feeding stuff law are reported of a number of samples of cotton-seed meal, oil meal, linseed meal, gluten meal and feed, germ oil meal, distiller's grains, barley sprouts, malt sprouts, mixed feeds, and cereal breakfast food by-products, corn meal, poultry feeds, animal meal, and similar products.

Licensed concentrated feeding stuffs, F. W. WOLL and G. A. OLSON (*Wisconsin Sta. Bul. 97*, pp. 48).—In accordance with the provisions of the State feeding stuff law, analyses were made of a number of samples of cotton-seed meal, oil meal, gluten meal and feeds, hominy feed, corn feeds, corn bran, corn hearts, mixed corn and oat feeds, oat clippings, sugar food, cereal breakfast food by-products, calf meal and other dairy feeds, blood meal, granulated bone, beef meal and similar poultry feeds; wheat bran and middlings, alone and mixed, wheat shorts, red-dog flour, wheat germs, dust, screenings and damaged wheat, rye bran, middlings, and shorts; oat shorts, meal, and hulls; barley feed and sprouts, dried malt and brewers' grains; buckwheat bran, middlings, and shorts, flaxseed meal, rice bran, pigeon grass seed, spent hops, and several mixed grains and feeding mixtures.

The origin of fat in the animal body, G. ROSENFELD (*Chem. Ztg.*, 26 (1902), No. 93, p. 1110).—In a paper presented before the Chemical Society of Berlin the author reported metabolism experiments which, in his opinion, showed that the formation of fat from protein in the animal body is not demonstrated. He believes that fat in food passes into the body tissue without much change and that fat is formed from carbohydrates which apparently has a low content of oleic acid.

The rôle of salt in animal feeding, A. DISSARD (*Rev. Agr. Réunion*, 8 (1902), No. 11, pp. 444-448).—In this article, which was quoted from *Agriculture Nouvelle*, the importance of salt is discussed, as well as the amounts which should be fed, and related topics.

The adipolytic ferment in the stomach, F. VOLHARD (*Ztschr. Klin. Med.* [Berlin], 43 (1901), pp. 397-419; *abs. in Ztschr. Untersuch. Nahr. u. Genussm.*, 5 (1902), No. 20, pp. 969, 970).—According to the author the digestive juice of the stomach contains a ferment which causes cleavage of fat and the extract of the mucous membrane of the stomach contains the zymogen of this ferment. The properties of both of these bodies are discussed.

Concerning the ferment in the mucous membrane of the pylorus, F. KLUG (*Arch. Physiol.* [Pflüger], 92 (1902), No. 6-7, pp. 281-292).—A number of experiments are reported.

Influence of the spleen on the assimilation of nitrogen, I. BYELAGOOSKI (*Zap. Novo-Alexandri. Inst. Selsk. Khoz. i. Iyosov.*, 14 (1901), No. 1, pp. 205-211).—Experiments made with dogs in which the income and outgo of nitrogen was determined, showed that the removal of the spleen did not materially affect the assimilation of this element.—P. FIREMAN.

Experiments on feeding animals carried on in Seine-Inférieure in 1901, F. LAURENT (*Compt. Rend. Cong. Soc. Aliment. Rat. Bât.*, 6 (1902), pp. 53-61).—Feeding tests with steers, milch cows, and sheep are reported in which the value of commercial concentrated feeds was studied. In the first test, which was made by Prunier, 12 steers, divided into 4 lots of 3 each, were fed linseed cake, gluten cake, sesame cake, and decorticated peanut cake, in addition to a coarse fodder. In the 56 days of the test the total gains made were 78, 86, 85, and 87 kg. per lot, and the corresponding cost of a kilogram of gain was 14.4, 9.8, 10.6, and 13.2 cts. The conclusion is drawn that all the cakes were satisfactory and that their selection should be determined by market prices.

The comparative feeding value of wheat bran, decorticated cotton-seed cake, decorticated peanut cake, and sesame cake was tested by Luquet with 4 lots of 4 cows each. Each cow was fed 3 kg. of the concentrated feed in addition to a basal ration of 12 kg. fodder beets, 1 kg. chaffed straw, and 10 kg. meadow hay per head. In 56 days the total quantity of milk produced by the 4 lots was 2,333.5, 2,462.0, 2,494.5, and 2,473.5 liters, respectively. During the feeding period lots 1, 3, and 4 lost respectively 58, 38, and 24 kg. in weight, and lot 2 gained 116 kg. In the author's opinion the tests showed that it is profitable to use concentrated feeds like those tested. The cotton-seed cake proved to be especially satisfactory, securing an abundant flow of milk of first quality and maintaining the cows in good condition.

Using 6 lots of 5 sheep each, E. Brayé tested the comparative value of maize, colza cake, decorticated cotton-seed cake, sesame cake, peanut cake, and linseed cake. The basal ration consisted of 1 kg. oat straw, 0.5 kg. chaffed straw, 5 kg. fodder beets, and 1 kg. alfalfa rowen per head per day. During the first two-thirds of the tests, which covered 60 days, each sheep was fed 500 gm. per day of the concentrated feed, and during the last third of the period 600 gm. per day. At the beginning of the test the average weight of the sheep varied from 259.5 kg. for lot 1 to 311 kg. for lot 6. The total gain of the 6 lots was 29.5, 21, 21, 21.5, 13.5, and 14 kg., respectively. Rating the value of the gains in weight at 20 cts. per kilogram, the gains ranged in value from \$2.70 with lot 5 to \$5.90 with lot 1. According to the author, full-grown

sheep require for fattening a ration with a wide nutritive ratio, better results being obtained when the ratio was 1:8.5 than when it was 1:4 or 1:5. Commercial concentrated feeds are regarded as useful for fattening sheep and the choice must be determined by their relative cost. Such feeding stuffs should supplement a quantity of coarse fodder sufficient to maintain a regular action of the digestive functions.

Alfalfa v. sorghum for wintering calves, E. A. BURNETT (*Nebraska Sta. Bul. 75, pp. 3-9, figs. 2*).—The author reports 2 tests on the feeding of young beef cattle. In the first the relative value of alfalfa and sorghum was tested with 3 lots of calves, lots 1 and 2 containing 6 grade Herefords each and lot 3 containing 6 grade Short-horns. After a preliminary period of 2 months, during which all the calves were fed on mixed grass and clover pasture and later given some alfalfa hay and grain (corn, bran, and oats 2:1:1), the experiment proper began on December 1 and covered 141 days. Lots 1 and 2 were fed 6 lbs. per head of alfalfa hay per day and lot 3 the same amount of sorghum hay. All the lots were fed at first 5 lbs. of corn, oats, and bran, 2:1:1, per head daily, the amount being gradually increased to 8 lbs. At the beginning of the test all the calves averaged 339 lbs. in weight. The average gain of the 3 lots during the test was 236 lbs., 244 lbs., and 218 lbs. per calf, the total grain eaten being 1,032 lbs. per head and the total hay 1,183 lbs. In other words, there was a gain of 22 lbs. per calf in favor of alfalfa hay over sorghum hay.

In the second test, which was made to compare pasturage with and without grain, the animals mentioned above were rearranged in 2 lots so that each contained one-half of those previously fed the alfalfa and the sorghum rations. Two Aberdeen-Angus steers of about the same weight were also included in the lot fed grain. Lot 1 was kept from May 1 to November 1 on a 16-acre pasture containing brome grass, mixed grasses, and 3 acres of alfalfa. On account of drought the feed was poor during a part of the time. Lot 2 also had the run of a pasture and throughout the test was fed in addition at first corn meal only and later corn and bran 3:1, the total amount of corn meal eaten being 1,893 lbs. and of the bran 260 lbs. The average gain in the lot on pasture only was 292 lbs. and in the lot receiving grain in addition to pasturage it was 404 lbs. The steers were sold for slaughtering, those in lot 1 being regarded by an expert as worth \$4 per 100 and those in lot 2 \$5.75 per 100. The estimated profit in lot 1 was \$2.01 per animal. With the Herefords in lot 2 it was \$5.39 per head, and with the Aberdeen-Angus steers in this lot, \$5.56 per head. According to the author this experiment shows that when steers are to be marketed in the fall or early winter there is more profit in summer feeding grain in addition to pasturage. Where steers are to be winter fed on grain for a spring market, there is more profit to feed no grain when on pasture.

Raising calves for beef production—skim milk v. sucking dam, E. A. BURNETT (*Nebraska Sta. Bul. 75, pp. 24-30, fig. 1*).—To study the effects on the growth after weaning of calves fed skim milk as compared with those allowed to run with their dams, 2 lots of 3 animals each, formerly included in a test comparing skim milk and whole milk (E. S. R., 13, p. 174), were fed for 63 weeks, the tests being divided into 3 periods of 147 days each. During the first period all were fed 789 lbs. alfalfa hay and 896 lbs. grain (corn and bran, 3:1). During the second period the steers were pastured and fed per head daily 8 lbs. of corn, oats, and bran, 2:1:1. At the end of this period one of the animals previously fed whole milk was withdrawn from the experiment. The remaining 5 were fed corn, oats, and bran, 2:1:1, in addition to alfalfa hay and roots, the total amount of corn eaten being 2,575 lbs., hay 1,538 lbs., and roots 1,015 lbs. During the first period the average gain of the skim-milk calves (lot 1) was 292 lbs. per head and that of the whole-milk calves 343 lbs. During the second period the average gains were 280 and 250 lbs. per head, respectively, and during the third period 332 and 335 lbs. Considering the test as a whole, the average gain of the 2 lots was the same, namely, 903 lbs. per head. In other words, the character of the feed before weaning did not exert a marked influence on subsequent gains.

The feeding was continued with 1 animal from each lot for 7 months on a ration of mixed grain and alfalfa hay, these materials being consumed by the skim-milk steer in the proportion of 6.9:1 and by the other steer in the proportion of 6.1:1. The total gains made were 345 and 325 lbs., respectively, the feed eaten per pound of gain being 13.17 and 13.94 lbs. At the close of the test the steers were exhibited at a stock show in Chicago. The skim-milk steer sold for \$7.65 per 100, the other was awarded 2 prizes. According to the author this steer "during the last 2 years of his life required 6.6 lbs. of grain to produce 1 lb. of gain and less than 10 lbs. of total food to produce a pound of gain, not counting the food secured during 358 days on pasture. This record would tend to show that finished cattle can be economically produced if they are so fed that they continue to make good gains up to the time when they are finished. . . . This steer is a conspicuous example of the effect of good blood in improving the common cattle of the country."

Raising calves with skim milk, C. H. ECKLES (*Missouri Sta. Bul.* 57, pp. 52, figs. 2, dgm. 2).—Raising calves on skim milk is discussed with special reference to local conditions, the author summarizing the matter as follows:

"The calf should be taken away from its mother by the third day, or earlier. The calf should have its mother's milk for about 2 weeks. The proper amount to feed a calf the first 2 or 3 weeks is about 5 or 6 qts. per day, and no more can be given without danger of indigestion. As the calf grows older it will take more, but never should have more than 8 or 9 qts. per day. The milk must be fed always at about blood heat. Cold milk will almost always cause scours if fed a young calf. When the calf is about 3 weeks old the milk ration is gradually changed to skim milk, using about a week to make the change."

The value of skim milk for feeding pigs and poultry is also discussed, the work of a number of stations being cited.

Wintering calves on roughness, E. A. BURNETT and H. R. SMITH (*Nebraska Sta. Bul.* 75, pp. 31, 32).—The value of adding grain to a winter ration of alfalfa and prairie hay (4:1) was tested with 2 lots of 6 Aberdeen-Angus steers, averaging nearly 500 lbs. in weight. Lot 1 received only the hay and lot 2 grain in addition. The average gains during the 91 days of the trial were 100 and 185 lbs., respectively, lot 1 requiring 14.87 lbs. of hay per pound of gain and lot 2 7 lbs. of hay and 1.9 lbs. of grain, the cost of a pound of gain in the 2 cases being 6 cts. and 4.66 cts., respectively, and the calculated net profit \$4.74 and \$5.73. According to the author the test shows that "it is ordinarily more economical to feed a small grain ration even when good gains can be secured on hay alone."

Results of calf-feeding tests at the Kleinhof-Tapiau Experiment Station and Dairy School, HERTCHER (*Landw. Wehnl. Schleswig-Holstein*, 52 (1902), No. 45, pp. 868-871).—The comparative feeding value of raw and cooked milk with and without the addition of salts was tested. The salts selected were such as would restore the curdling power of milk. The milk was cooked by passing live steam into it. Lot 1, made up of 6 calves, was fed raw milk; lot 2 (7 calves), cooked milk; lot 3 (6 calves), cooked milk with 10 cc. of 20 per cent of common salt solution added per liter; lot 4 (3 calves), cooked milk with 1 cc. of 40 per cent calcium chlorid solution per liter; lot 5 (3 calves), cooked milk with 2 gm. of powdered calcium citrate per liter; and lot 6 (2 calves), cooked milk with 5 cc. of 12 per cent solution of monocalcium phosphate per liter. The test covered 10 weeks. The calves ranged in weight at the beginning from 26 to 73.5 kg. each. The amount of milk which the author calculates was required per kilogram of gain in weight in the 6 lots was as follows: 11.11, 10.82, 10.45, 13.40, 11.06, and 12.18 kg., respectively. According to the author these results do not substantiate the idea often held that calves require more cooked than raw milk to produce a given amount of gain. The addition of common salt to cooked milk is regarded as satisfactory, and calcium chlorid was regarded as the least satisfactory of the salts tested.

Fattening steers, T. SHAW (*Minnesota Sta. Bul.* 76, pp. 225-265).—Several problems connected with the fattening of steers were studied in the 3 feeding tests reported. The first trial, covering 140 days and divided into 5 periods of 4 weeks each, was carried on during the winter with 3 lots each containing 2 steers. Those in lot 1, according to the author, possessed "what may be termed a fairly good beef form." Those in lot 3 were large and somewhat rangy, i. e., they were not of the type most suitable for fattening, while those in lot 2 were intermediate in type. The steers weighed about 1,100 lbs. each. The 3 lots were fed the same mixture of bran, ground barley, and ground corn, with oil cake in addition during the last 3 periods. They were also fed 20 lbs. of corn silage per head daily and all the hay they would eat up clean. The average daily gain was: Lot 1 (beef type), 1.62 lbs.; lot 2 (rangy steers), 1.61; and lot 3 (intermediate type), 1.72 lbs.; and the cost of a pound of gain was 4.8 cts., 4.49 cts., and 4.9 cts., respectively. Practically the same amount of feed was eaten per head per day by all the steers. The estimated profit was \$8.41, \$5.04, and \$3.21, respectively.

"In this experiment the steers of the approved meat-producing types did not show any superior capacity to make increase over those possessed of more or less undesirable form, though similarly bred. Notwithstanding [this fact], there is more profit in finishing steers of the approved types, owing to the greater value relatively of the finished product.

"It is extremely probable there is also less profit in growing animals of undesirable types up to the fattening period, because of their smaller value relatively when thus far grown. The greater value of steers of the approved type as compared with those opposite in character and possessed of essentially similar blood is owing to the superior value of the meat in the carcass rather than to greater power to make increase."

In the second test a lot of 5 steers was fed for 84 days (6 periods of 2 weeks each) what the author regards as a forcing ration, and a second lot of 5 steers was fed for 140 days (5 periods of 4 weeks each) a ration containing the same kinds of feed but in different proportions, the object being to study the relative merits of long and short feeding periods. The grain ration of both lots consisted of bran, ground corn, and oil cake, the proportion varying in the different lots and in the different periods. At the beginning of the trial it was planned to feed 10 lbs. of grain per head daily to the steers in lot 1, and increase the amount to 20 lbs. during the last period. It was further planned to feed 8 lbs. of grain at the beginning to lot 2 and increase the amount to 12 lbs. at the close. All the steers were also fed as much timothy hay and clover as they would eat and in addition for 42 days they were given 20 lbs. of corn silage per head per day. It was found that the steers in lot 1 could not consume the full allowance of grain. On the other hand, the animals in lot 2 ate all the grain supplied, but "as they suffered somewhat from scouring while the silage was being fed to them, this of course hindered the gains that would otherwise have been made."

In the 12 weeks they were fed the steers in lot 1 consumed 14.2 lbs. of grain, 10.3 lbs. of hay, and 8.6 lbs. of silage per head daily. In the same time those in lot 2 ate 8.9 lbs. of grain, 11.1 lbs. of hay, and 8.4 lbs. of silage. During the remainder of the time they were fed the average amount of grain eaten was 11.5 lbs. per head and the hay 15.7 lbs. At the beginning of the trial the steers in lot 1 weighed 1,153 lbs. on an average and those in lot 2 weighed 1,212 lbs. The average daily gain per head in lot 1 was 1.3 lbs. and in lot 2 it was 1.4 lbs. The cost of a pound of gain in lot 1 (fed the forcing ration for a short period) was 8.9 cts. In the case of lot 2 the cost of a pound of gain for a corresponding period was 5.82 cts., or for the test as a whole 6.19 cts. The steers were sold for slaughtering, the profit in the 2 lots being \$3.25 and \$10.02 per steer.

According to the author, when steers were fed a forcing ration of grain for a short period the increase in weight was not proportional to the amount eaten owing to the

fact that more or less of the meal fed was wasted. It was observed that these steers were more apt to be off their feed than those fed a lighter grain ration. In general the author considers that feeding the light grain ration for a long period was much more satisfactory than feeding the forcing ration for a short period.

In the third test, which covered 5 periods of 28 days each, the comparative merits of feeding in stables and open sheds were studied with 2 lots, each containing 7 grade Shorthorn steers of good quality, weighing on an average 1,583.3 and 1,503.9 lbs. each, respectively. Both lots were fed corn, bran, oats, and oil cake in addition to hay, the kind and amount of grain varying somewhat in the different periods. In general the object was to decrease the amount of bran and increase the amount of corn as the test progressed. The amount of oats fed was small and they were discontinued before the close of the trial. Oil cake was introduced in the second period, and the amount fed was increased as the test progressed. The steers in lot 1, fed indoors, gained on an average 1.74 lbs. per head daily and those in lot 2 (fed in a shed with a yard) gained 2.26 lbs., the cost of a pound of gain being respectively 6.47 and 5.61 cts. On an average the steers in lot 1 ate 11.31 lbs. of hay and 13.36 lbs. of grain per head daily. Similar values for lot 2 were 10.74 lbs. and 16.21 lbs. The steers were sold for slaughtering, the average profit per steer in lot 1 being \$8.38 and \$10.10 in lot 2. Further experiments are regarded as necessary before definite conclusions can be drawn.

Wheat v. corn in a ration for fattening steers, E. A. BURNETT and H. R. SMITH (*Nebraska Sta. Bul.* 75, pp. 10-18).—After a preliminary period of 4 weeks, wheat v. corn was studied with 20 steers used in a test above reported (p. 792), divided into 4 lots in such a way that there were 6 animals in lot 1 and 4 in lot 4, while lots 2 and 3 each contained 5. The test began November 1, and covered 23 weeks, being divided into 2 periods of 11 and 12 weeks, respectively. During the first period lots 1 and 3 were fed wheat and bran, 4:1, and lots 2 and 4 corn and bran in the same proportion, all the lots being given alfalfa hay in addition. In the second period lots 1 and 3 were fed wheat, corn, and oil meal, 7:1.5:1.5, and lots 2 and 4 corn, wheat, and oil meal 7:1.5:1.5, all receiving in addition alfalfa hay, prairie hay, and wheat straw about in the proportion of 2:1:1. At the end of the first period 2 steers in lot 1 and 1 in lot 2 were withdrawn for use in class room instruction. Considering the test as a whole the average gain per steer in the 4 lots was 294, 279, 349, and 326 lbs., respectively; the total grain eaten 2,248, 2,248, 2,425, and 2,424 lbs., respectively, and the total coarse fodder 1,397, 1,397, 1,392, and 1,397 lbs., respectively. On an average it was calculated the steers fed wheat required 11.85 lbs. of feed per pound of grain, and those fed corn 12.48 lbs. The steers were sold and slaughtered, the dressed weight of lots 1 and 2 being 64.48 per cent of their live weight and that of lots 3 and 4 being 62.28 per cent.

"During the period when alfalfa only was fed as roughness the steers were often in too laxative a condition to produce the best results, and the addition of prairie hay and wheat straw in the ration overcame this trouble in the second period of the experiment. . . . This one experiment is not conclusive evidence that wheat exceeds corn in feeding value, but indicates that the feeding values of wheat is 5 per cent greater than corn for cattle.

"This experiment indicates that a 6-months' feeding period in this case is more profitable than a 12-months' feeding period, [and] shows a profit of \$10.14 per head on summer-fed yearling cattle compared with \$19.63 on cattle of the same quality which were on grass only during the summer [p. 792]. Taking the statement for the year, the cattle fed 12 months show a profit of \$15.49 against a profit of \$21.64 on the cattle fed grain during the winter only.

"The steers were followed by 20 pigs weighing 1,370 lbs. at the beginning of the test. In addition to what they could gather they were fed a total of 2,878 lbs. of

shorts, making a gain of 1,340 lbs. The estimated net profit on the pigs was equal to \$72.17."

Comparison of shelter and rations in feeding steers, F. A. BURNETT (*Nebraska Sta. Bul.* 75, pp. 19-23).—The test proper, which was undertaken to study the importance of shelter, was begun after a preliminary period of 17 days, with 18 steers divided into 3 equal lots. The animals in lot 1 were each kept in a small yard having an open shed facing east, those in lot 2 in box stalls opening toward the south, and those in lot 3 in a single open yard with an open shed which faced south and with some protection on the north also. During the preliminary period the steers were all fed alfalfa hay and corn meal. During the 23 weeks of the test proper they were given alfalfa hay and grain, the steers in lots 1 and 2 receiving 8 lbs. of grain and from 12 to 16 lbs. of alfalfa hay per head daily. Those in lot 3 were fed first 6 lbs. of grain and 16 lbs. of alfalfa hay per head daily, the grain ration being increased and the hay ration diminished until in the latter part of the feeding period the grain amounted to from 16 to 20 lbs. and the hay to from 5 to 10 lbs. Two of the steers in lots 1 and 2 and all those in lot 3 were fed corn meal only, the grain ration of 2 animals each in lots 2 and 3 consisting of corn meal and oats 3:1, and of the remaining 2 animals in each of these lots of corn meal and bran 3:1. At the beginning of the test proper the average weight of the steers in lot 1 was 918 lbs. and of those in lots 2 and 3 it was 860 lbs. The average gain of the steers fed in open pens and sheds was 330 lbs., of those fed in open box stalls 400 lbs. and of those fed in a large open yard with a shed 315 lbs. Considering the gains with relation to the rations, the 10 steers on corn meal made an average gain of 372 lbs., the 4 steers on corn meal and oats 327 lbs., and the 4 on corn meal and bran 381 lbs., the total feed consumed per pound of gain ranging from 8.08 lbs. in the case of one of the steers fed corn meal in a box stall to 13.8 in the case of a steer fed in a shed with a yard on a corn-meal ration.

The steers were sold for slaughtering, yielding a profit of \$3.16.

"In these feeding operations, as in all feeding, the large gains proved to be the cheapest gains, and these were not made by any one ration. All the extremely large gains were made by steers in the box stalls in the shed. . . . In this experiment corn meal and alfalfa in the box stall gave the largest gain. Corn meal, bran, and alfalfa in the box stall gave the second largest gain. Corn meal, bran, and alfalfa in the open shed and pen gave the third largest gain."

Dehorning fattening steers, G. H. TRUE (*Arizona Sta. Rpt.* 1902, pp. 259, 260).—Twenty-one range steers and 6 heifers were dehorned with clippers. The average loss of weight in a week was 75 lbs. per head. One steer which had not been dehorned lost 20 lbs. in the same time. The next day after dehorning creosylic ointment and pine tar were applied to the wounds of all but one of the animals. "A week later the one not treated had worms in both sides of her head, while amongst those treated only one had worms. All were given a second treatment and no further trouble was had."

Cattle, H. J. MONSON (*Jour. Khediv. Agr. Soc. and School Agr.*, 4 (1902), No. 2, pp. 69-74, pls. 13).—An illustrated description of some Egyptian cattle, the subject being discussed with a view to securing improvement in local stock.

Fattening lambs, T. SHAW (*Minnesota Sta. Bul.* 75, pp. 193-224, figs. 8).—Three experiments, which have to do with fattening lambs for market, are reported. In the first the relative merits of feeding range lambs and range wethers were studied with 1 lot of 20 wethers and 4 lots containing 30 lambs each. The wethers (lot 1) were Merino grades. The lambs in lots 2, 3, and 4 were, respectively, Cotswold, Oxford Down, and Shropshire grades. Those in lot 5 were essentially of Merino blood. The test began October 31 and covered 18 weeks, being divided into 5 periods, the last covering 2 weeks and all the others 4 weeks each. Uncut hay, cut sorghum, and different mixtures of bran, unground corn and oil cake were fed. Considering

the test as a whole, the wethers consumed 2 lbs. of grain and 1.5 lbs. of coarse fodder per head per day, and the lambs on an average 1.5 lbs. of grain and 1 lb. of coarse fodder. At the beginning of the trial the wethers weighed on an average 100.8 lbs. and the lambs 66.4 lbs. The average daily gain of the wethers was 0.24 lb. and of the lambs 0.23 lb., in the latter case the amounts ranging from 0.2 with lot 5 to 0.24 with lots 3 and 4. In the case of the wethers the cost of a pound of gain was 4.99 cts. and in the case of the lambs the amount varied from 3.6 cts. with the Oxford grades to 4.07 cts. with the Merino grades, averaging 3.81 cts. The average profit per lamb was 38 cts. and per wether 3 cts. The fact is pointed out that although the wethers consumed 40 per cent more feed than the lambs their increase in weight was but 3.4 per cent greater. According to the author, while the difference in relative adaptability for fattening of the lambs of the different lots "was not very great, it was the lowest in the lambs of the Merino grades."

In the second test the value of a ration of corn and bran with and without oats was tested with 16 Dorset lambs divided into 2 equal lots, the lambs in the 2 lots weighing respectively 90 lbs. and 88 lbs. each. The test covered 3 periods of 28 days. Throughout the test lot 1 was fed bran and corn in different mixtures, and lot 2 bran, corn, and oats, both lots receiving clover hay in addition. The average amount of grain eaten per head daily by all the lambs in both lots was 1.5 lbs. and the hay 0.8 lb. The average daily gain per head of the lambs fed bran and corn was 0.1, and of those fed oats in addition 1.5 lbs., the cost of a pound of gain in the 2 cases being 8.62 and 6.28 cts. At the close of the test the lambs were sold for slaughter, the net profit per lamb in the 2 lots being \$1.83 and \$1.97, respectively. As pointed out by the author, the lambs fed oats in addition to corn and bran gained 36 per cent more in weight during the test than the others, although they consumed practically the same amount of feed. The profit on these lambs was also greater, although their ration was somewhat more expensive. The conclusion is therefore drawn that "with prices in reasonable balance, bran, corn, oats, and hay make a more satisfactory ration for lambs that are being fattened than bran, corn, and hay."

Sixteen Dorset grade lambs, divided into 2 equal lots, were used for the third test, which was undertaken to study the comparative merits of well-balanced and badly balanced rations. The test was divided into 3 periods of 4 weeks each. The grain ration of lot 1 consisted of unground corn and bran, and that of lot 2 of unground corn, oats and barley, and bran, the proportion in each case varying in the different periods. Both lots were fed corn fodder, and in addition lot 2 was fed sliced mangel-wurzels and carrots on alternate days. At the beginning of the trial the average weight of the lambs in the 2 lots was 93 and 96.9 lbs., respectively. The average daily gain of the lambs in lot 1 was 14.8 lbs. and of those in lot 2 (fed the better balanced ration), 25.1 lbs., the cost of a pound of gain being 7.17 cts. and 6.92 cts., respectively. On an average the lambs in lot 1 ate 1.9 lbs. of grain and 1.8 lbs. of corn fodder per head per day, while those in lot 2 ate 2.1 lbs. of grain, 1.7 lbs. of corn fodder, and 4.9 lbs. of roots. Shortly after the test the lambs were slaughtered, the average net profit in the 2 lots being 34 cts. and 49 cts., respectively. The author believes that "the finished product resulting from feeding mixed grain and roots was superior to that from feeding corn and bran without roots. A diet of grains with roots added, notwithstanding its greater cost, may be more economical when fattening lambs than a diet more restricted as to the grain factors composing it, in spite of the greater relative cheapness of the latter."

"In this experiment the ration composed of bran, corn, oats and barley, field roots and corn fodder, was more satisfactory than one composed of bran, corn, and corn fodder only."

Hand-feeding sheep, F. B. GUTHRIE (*Agr. Gaz. New South Wales*, 13 (1902), No. 10, pp. 1049-1051).—Detailed statements are made concerning the rations fed to ewes, rams, and lambs during the recent local drought, and concerning the cost of feeding.

Hand-feeding stock in the Moree District, E. R. SCOTT (*Agr. Gaz. New South Wales*, 13 (1902), No. 10, pp. 1051-1053).—The experience of a number of sheep feeders is reported. Among the feeding stuffs tested during the drought were molasses and prickly pear. It was found that when steamed sufficiently to destroy the spines the latter would sustain life, but would not cause animals to put on flesh.

How far should sheep be hand-fed in times of drought before their value is exceeded? W. C. DOWLING (*Agr. Gaz. New South Wales*, 13 (1902), No. 9, pp. 923, 924).—The problem of successfully feeding sheep under local conditions in times of drought when they can not get their feed on the range is discussed.

Salt for sheep (*Abs. in Agr. Jour. and Min. Rec. [Natal]*, 5 (1902), No. 11, p. 361).—The value of salt for sheep is indicated by a feeding experiment made in France with 3 lots fed alike on a ration of hay, straw, potatoes, and beans for 124 days. Lot 1 was given no salt. One-half ounce per head daily was fed to lot 2, and 0.75 oz. per head daily to lot 3. The sheep in lot 2 gained 4.5 lbs. per head more than those in lot 1, and 1.25 lbs. more than those in lot 3. The conclusion was drawn that too much salt can be given as well as too little. The sheep fed salt produced 1.75 lbs. more wool and had a better fleece than those given no salt.

The improvement of pasture as tested by sheep (*Dept. Agr. Cambridge Univ. Rpt. 1902*, pp. 28-38).—Continuing previous investigations (E. S. R., 13, p. 483), experiments are reported in which the value of different manures for pastures was studied by the gains made by sheep pastured on test plats. In the experiment in Cambridgeshire the sheep receiving 0.95 lb. per head daily of linseed cake pastured on a plat not manured made an average weekly gain of 2.37 lbs. Those pastured on plats which the previous year were manured with 0.5 ton basic slag, with 0.25 ton basic slag, and with 7 cwt. superphosphate per acre gained per head per week, respectively, 1.35, 2.34, and 2.41 lbs. The corresponding gain of sheep on an unmanured plat was 1.35 lbs.

In the experiment carried on in Essex, one plat was unmanured; another was unmanured, but the sheep pastured on it were fed 1.75 lbs. linseed cake per head per day. The other plats were manured respectively with 10 cwt. basic slag, with 5 cwt. basic slag, with 7 cwt. superphosphate, and with 7 cwt. superphosphate plus 100 lbs. of sulphate of ammonia per acre. Eight sheep were pastured on all the plats except the last, and on this there were only 6. The average monthly gains per lot during the 4 months' test were 4.25, 21.75, 15.25, 6.25, 8.5, and 11.75 lbs., respectively.

In the experiment in Norfolk, one plat was unmanured. Another was also unmanured, but the sheep pastured on it were fed per head daily 1 lb. of linseed cake and rough cotton-seed cake, 1:1. The other plats were manured with 0.5 ton basic slag, with 14 cwt. superphosphate, with 14 cwt. superphosphate and 3.5 cwt. kainit, and with the same amount of superphosphate and 1 cwt. nitrate of soda per acre, respectively. In 3 months the sheep pastured on the plats gained per head per week 1.9, 2.7, 2, 1.6, 1.7, and 1.7 lbs., respectively.

The yield and character of the hay grown on the different plats is discussed and experiments in Northamptonshire briefly mentioned.

Experiments on farming pasture at Waresley (*Dept. Agr. Cambridge Univ. Rpt. 1902*, pp. 39-49).—The effect of different manures on the yield of hay, as shown by the gains made by sheep pastured on sample plats, was studied, the experiment being a continuation of work previously reported on the value of different mixtures for seeding poor clay land formerly under tillage (E. S. R., 13, p. 638). In one case the land received no manure. In another no manure was added, but the sheep were fed 0.89 lb. per head daily of linseed cake. Two other plats were manured respectively with 10 cwt. of basic slag and 10 tons of manure per acre. The average gain per sheep per week on each of these 2 plats was 2.3 lbs. and on the remaining 2 plats 2.4 lbs.

The yield and character of the hay on the plats were also studied. According to the author "the yield of hay has been considerably influenced by the seeding, but neither the yield of hay nor the growth of the sheep has been affected by the manures."

Sheep-shearing test at Halle in 1901, C. LEHMANN (*Arb. Deut. Landw. Gesell.*, 1902, No. 75, pp. 99, figs. 72).—Detailed results are given of a sheep-shearing test. The average live weight of the 72 animals included was 57.2 kg. and that of the unwashed fleece 5.06 kg.

Maltese goats, J. H. GROUT (*U. S. Consular Rpts.*, 71 (1903), No. 268, pp. 103, 104).—The milch goats which furnish the greater part of the milk supply of Malta are described and brief notes given on the methods followed in the local goat industry.

Wheat compared with other grains for pigs, H. R. SMITH (*Nebraska Sta. Bul.* 75, pp. 33-36, fig. 1).—Wheat was compared with other grains in a test made with 8 lots, each containing 4 Tamworths and Yorkshires, the so-called bacon type, and 2 Duroc-Jerseys and Berkshires, the so-called block type. Lot 1 was fed whole wheat dry, lot 2 whole wheat soaked 18 to 24 hours, lot 3 ground wheat, lot 4 ground wheat and corn, 1:1; lot 5 ground wheat and rye, 1:1; lot 6 ground wheat and shorts, 1:1; lot 7 ground corn, and lot 8 ground rye. The average weight of the pigs at the beginning of the trial was about 170 lbs. The average daily gain in the 8 lots was 0.63, 0.70, 0.76, 0.74, 0.70, 0.71, 0.71, and 0.67 lb., respectively, the feed eaten per pound of gain being 6.37, 5.75, 5.59, 5.86, 6.21, 6.12, 6.09, and 6.24 lbs., respectively. The pigs were sold at \$5.525 per 100, the profits ranging from \$3.60 with lot 7 to \$7.81 with lot 2, the total profit for the 8 lots being \$44.13. One of the pigs of each type fattened on corn and 1 of each type fattened on wheat were slaughtered at the station.

"Little difference was observed between carcasses of wheat-fed and carcasses of corn-fed hogs except that perhaps a little more lean meat was noticeable on the wheat hogs.

"The larger proportion of lean meat on the bacon hogs was very apparent."

The author's conclusions follow:

"Wheat can be profitably substituted for corn in feeding pigs so long as the price of wheat is not more than 9 per cent higher than corn. In feeding wheat to hogs it should first be soaked or ground. Of the two, soaking is more economical unless the grinding can be done for about 2 cts. per hundred pounds."

Corn v. wheat for pigs on alfalfa pasture, E. A. BURNETT and H. R. SMITH (*Nebraska Sta. Bul.* 75, pp. 37, 38).—The 18 cross-bred Tamworth and Duroc pigs, which had followed steers in a test noted above, were divided into 3 equal lots, lot 1 being fed corn, lot 2 corn with 5 per cent of dried blood added, and lot 3 wheat. In addition all the pigs were pastured on alfalfa and turned on rape once a week. At the beginning of the trial, which covered 6 weeks, the average weight of the pigs in the 3 lots was 146, 145, and 147 lbs., respectively, the average daily gain being 1.22, 1.3, and 1.3 lbs., respectively. The feed consumed per pound of gain was 4, 3.76, and 3.76 lbs., while the cost of the feed per pound of gain was 4, 4.04, and 4.13 cts., respectively. Not counting pasturage and labor the greatest profit, \$3.88, was obtained with lot 2, and the smallest, \$3.77, with lot 1. According to the author, "The addition of 5 per cent dried blood to corn makes a ration containing the same amount of digestible protein and the same nutritive ratio as the ration of wheat. It is significant that the gains on these 2 lots were the same."

Egg-laying competition conducted at the Hawkesbury Agricultural College, D. S. THOMPSON (*Agr. Gaz. New South Wales*, 13 (1902), No. 2, pp. 1139-1145).—Detailed statements are given of the number of eggs laid by different breeds and flocks.

Statistics of farm animals (*Twelfth Census of the United States, Census Rpts.*, vol. 5 (Agriculture, pt. 1), pp. CXLIII-CLXV, CLXXXVI-CCXXXII).—Statistics, representing conditions on June 1, 1900, are given of the different farm animals kept in

the United States, their value, distribution, and related topics. In addition, under each class, such subjects are discussed as the growth of the industry, markets and marketing, and in some cases feeds and feeding are also briefly spoken of.

Domestic animals.—The total number of farm animals on farms and ranges was 215,822,238, the total value being \$2,981,722,945, of which sum the neat cattle constituted 49.5 per cent; horses, 30.1 per cent; mules, 6.6 per cent; asses and burros, 0.2 per cent; sheep, 5.7 per cent; swine, 7.8 per cent; and goats, 0.1 per cent. Of the value of neat cattle, over one-half is represented by the two classes of cows, those "kept for milk" and those kept for breeding and designated as "not kept for milk."

Neat cattle.—The total number of neat cattle was 69,438,758, of which 97.7 per cent were on farms and ranges and 2.3 per cent in barns and inclosures elsewhere. The estimated total value of neat cattle was \$1,517,602,351. Of the 53,843,513 neat cattle 1 year old and over 28.7 per cent were steers, of which the great majority were raised for beef, only a few being work oxen.

Horses.—According to the estimates there were in the United States 18,390,441 work horses and 2,826,447 too young for work, making a grand total of 21,216,888 horses, of which 86.2 per cent were on farms and ranges and 13.8 per cent in barns and inclosures elsewhere. The total value of all the horses was \$1,050,969,093.

Asses and burros.—On farms 95,603 asses and burros were kept and 15,847 elsewhere, the total value of all being \$6,789,938.

Mules.—The total number of work mules 2 years old and over was 2,925,923, and the number of growing mules under 2 years was 519,106, making a grand total of 3,445,029 mules, of which 95 per cent were on farms and ranges.

Sheep and wool.—According to the reports received there were 61,837,112 sheep, of which 21,719,939 were lambs under 1 year, 32,058,920 ewes 1 year and over, and 8,058,253 rams and wethers 1 year and over. All but 0.4 per cent of this number were on farms and ranges. The total value of all the sheep on farms was \$170,337,002, the lambs having an average value of \$1.94, the ewes of \$3.18, and the rams and wethers of \$3.36, the general average for sheep of all ages being \$2.76. The total number of fleeces shorn on farms and ranges was 44,092,948, having a total weight of 276,991,812 lbs. In addition it was estimated that the amount of wool from slaughtered sheep, i. e., pulled wool, was 33,000,000 lbs., making the total amount of wool 309,991,812 lbs.

Goats and mohair.—The total number of goats reported was 1,949,605, all but 4 per cent being on farms and ranges. The total value of the goats on farms and ranges was \$3,266,080. The total weight of the mohair fleeces produced in 1899 (the last figures given) was 961,328 lbs., the value being \$267,864.

Swine.—The total number of swine reported was 64,694,222, of which 62,876,108, or 97.2 per cent, were on farms and ranges, and 1,818,114, or 2.8 per cent, were in barns and inclosures elsewhere, the total value of all the swine in the country being \$238,736,548, which is equivalent to an average value of \$3.69 each.

Income from sales of live stock.—Estimates are given of the number of farm animals sold for slaughter and other purposes, the aggregate value, including horses and mules, being estimated at approximately \$1,000,000,000.

Poultry and eggs.—The total number of chickens, including guinea fowls, on farms and ranges was 233,598,085; the total number of turkeys, 6,599,367; geese, 5,676,863; and ducks, 4,807,358. According to the returns received poultry was kept on 88.8 per cent of the farms in the United States. The total value of the poultry raised on farms and ranges in 1899 was \$136,891,877. "The production of eggs in 1899 was 1,293,819,186 dozens, an average of 5.5 dozens per chicken. No consideration was given to turkeys, geese, or ducks in calculating this average, as eggs from those fowls are used mainly for breeding purposes." The total value of the eggs was \$144,286,158, or an average value of 11.2 cts. per dozen.

DAIRY FARMING—DAIRYING.

Feeding experiments with milch cows, 1900-1901, F. FRIS (*53. Ber. Kgl. Vet. Landbohøjskoles Lab. Landökon. Forsög [Copenhagen], 1902, pp. 30*).—This is a preliminary report on the results of the cooperative feeding experiments with milch cows conducted by the Copenhagen experiment station during the year 1900-1901. The plan of the experiments was similar to that of earlier work (E. S. R., 11, p. 780). The subject studied was the value of roots in comparison with grain. Four lots of 10 to 12 cows each were formed on 6 different dairy farms, and these were fed similar rations during a preparatory feeding period of 40 to 50 days. During the experimental period proper lot A received 7 lbs. grain (barley, rye, or oats, mixed) and $1\frac{1}{2}$ lbs. cotton-seed meal; lot B, 4 lbs. grain and $4\frac{1}{2}$ lbs. cotton-seed meal; lot C, 4 lbs. grain and $1\frac{1}{2}$ lbs. cotton-seed meal; and lot D, 1 lb. grain and $4\frac{1}{2}$ lbs. cotton-seed meal. In addition lots A and B were fed $4\frac{1}{2}$ lbs. dry matter in mangel-wurzels and lots C and D $7\frac{1}{2}$ lbs., all 4 lots receiving 6 $\frac{1}{2}$ lbs. hay and 10 lbs. straw. The nutritive ratios of the rations fed to lots A and C were between 1:8 and 1:9, and those of the rations fed to lots B and D between 1:5 and 1:5.5.

The average daily yield of milk per head for the different lots was as follows: Lot A, 22.4 lbs.; lot B, 23.7 lbs.; lot C, 22.5 lbs.; and lot D, 24.2 lbs. The average percentage of fat in the milk produced by the different lots during the experimental period proper was as follows: Lot A, 3.11; lot B, 3.16; lot C, 3.11; and lot D, 3.10 per cent. The fat content of the milk was not therefore appreciably influenced by the character of the rations fed.

The results show that 3 lbs. of grain and 3 lbs. of dry matter in roots had very nearly the same feeding value under the conditions of the experiments. Lots B and D were fed richer rations than lots A and C. In either case, however, grain and dry matter in roots were found to possess a similar feeding value whether the nutritive ratio was 1:5 or 1:9.

In the comparison of oil meals and grain feed the results of a series of experiments with milch cows conducted during 1891-92 (E. S. R., 4, p. 601) showed that oil-cake meal (rape seed, palm nut, and sunflower-seed meal mixed in equal parts) possessed an appreciably higher feeding value than similar amounts of mixed grains. By methods of calculations it was found that the feeding value of 1 lb. of grain was equivalent in feeding value to $\frac{2}{3}$ lb. of oil meals. In the same way the experiments of 1900-1901 furnished data showing that $\frac{2}{3}$ lb. of cotton-seed meal was equivalent to 1 lb. of grain. This ratio appeared to hold good whether a heavy or a light root feeding was practiced. Lots B and D therefore received $\frac{2}{3}$ lb. more cotton-seed meal than the equivalent of 3 lbs. of grain; hence the increased production of these lots.

The position of the experiment station on certain mooted questions in animal nutrition, particularly as to the value and applicability of the results of the cooperative Danish cow-feeding experiments to everyday conditions on the farm is explained and the practical value of the experiments maintained. The value of calculations of food equivalents, the use of data obtained by averaging the results for different farms, chemical analysis of feeding stuffs, and nutritive ratios are among the subjects discussed. It is argued that the feeding value of a fodder can not be established by means of chemical analysis with even approximate certainty. In practice, moreover, it is not possible to have chemical analyses made of the feeding stuffs employed, and the farmer must content himself by using figures for the average composition of feeding stuffs. Chemical analyses and nutritive ratios are looked upon as useful aids in controlling the composition of the feed rations rather than as means of determining their value. The relative valuation of food materials must be made by the farm animals themselves, and this finds expression in the figures of food equivalents, as suggested by Fjord. For conditions similar to those under which the experiments were

conducted the figures obtained for the "replacement value" (the equivalent figures) of the feed stuffs experimented with are therefore believed to give important information and to be of greater value to the farmer than calculations from an assumed average composition of feeding stuffs and assumed nutritive ratios. The equivalent figures for the following feeds have been determined in the feeding experiments with milch cows conducted by the station: One pound mixed grain (barley, oats, or rye)=1 lb. Indian corn=1 lb. wheat bran=1 lb. molasses feed=1 lb. dry matter in roots= $\frac{3}{4}$ lb. cotton-seed meal. These figures are averages only. Corn, bran, and dry matter in roots may often be found to be somewhat more valuable than the small grains, pound for pound, so that their replacement value may lie between 0.95 and 1, and that of molasses feed may vary between 1 and 1.05.—F. W. WOLL.

Feeding experiments with gluten feed, N. RITLAND (*Norsk Landmandsblad*, 21 (1902), No. 41, pp. 488-490).—An experiment with 8 cows is reported, the result of which indicated that 1 lb. of gluten feed has a somewhat higher feeding value than $\frac{1}{2}$ lb. rye bran and $\frac{1}{2}$ lb. cotton-seed meal.—F. W. WOLL.

Feeding experiments with corn-molasses feed for milch cows (*Ber. Norges Landbr. Høiskoles Virks.*, 1901-2, pp. 190-192).

The Hegelund method of milking, C. W. AARHUS (*Den Hegelundske Malkemetode*. Denmark, 1902, pp. 49, ill.).—This is a popular treatise on the subject of milking, particularly on the Hegelund method (E. S. R., 14, p. 286). The various manipulations are illustrated. The gain in production obtained by the use of this method is shown by a number of cases. The author states that by the adoption of the Hegelund method the product of the dairy may on the average be increased 12 per cent, partly through the production of more and richer milk, and partly through the resulting improvement in the dairy qualities of the cows. The effect of a careful and exhaustive system of milking on the dairy herd and in preventing diseases of the udder is discussed at some length.—F. W. WOLL.

Milking according to Dr. Hegelund's method, L. STEEN (*Christiania*, 1902, pp. 18; *Tidsskr. Norske Landbr.*, 1902, No. 9, sup.).—A popular discussion published by the Royal Society for Norway's Weal.—F. W. WOLL.

On milking, with special reference to clean milking, K. W. AADERMAN (*Landtmannen*, 13 (1902), No. 42, pp. 668-676).

Dairy herd record and creamery notes, R. W. CLARK (*Alabama College Sta. Bul.* 121, pp. 183-203).—A summary is given of the record of the station herd of about 8 cows for 2 years. The average annual production per cow was 3,954.6 lbs. of milk and 226 lbs. of butter. The cost of keeping was \$24.07, and the average cost of producing milk 5.5 cts. per gallon, and butter 11 cts. per pound. Data are given on the cost of raising 6 heifer calves. The average cost the first year was \$11.77, and the average cost to the time of calving was \$19.47. Methods suggested for the removal of the odor and taste of bitterweed and wild onion from milk and cream were tested. The compound in bitterweed responsible for the bad flavor was thought to be held largely or entirely by the milk serum and that in wild onion by the fat. The bitterweed taste was entirely removed from cream by washing. This was done by mixing the cream with 2 or more parts of water, at temperatures of 70° F. or above, and running the mixture through the separator. The other methods tested, such as feeding cows cooking soda and the addition of saltpeter to the cream, were unsatisfactory. In comparative tests of different systems of creaming the separator left on an average 0.03 per cent of fat in the skim milk, deep setting 1.3, and shallow pans 0.6 per cent, the temperatures being from 81 to 85° F.

In an experiment lasting 4 weeks 3 cows were fed a ration consisting of 9 lbs. of cotton seed, 3 lbs. of bran, and 10 lbs. of sorghum hay, and 3 were fed a ration consisting of 5½ lbs. of cotton-seed meal, 3 lbs. of bran, and 10 lbs. of cotton-seed hulls. There was practically no difference in the melting point and content of volatile fatty acids of the butter made from the 2 rations. During 2 months 9 cows on pasture

were fed different combinations of cotton seed, cotton-seed meal, and bran. Feeding cotton seed and cotton-seed meal, as compared with bran alone, apparently increased the melting point of the butter 1 to 3° C. The content of volatile fatty acids was not materially affected by the different rations. Tests were made of potassium bichromate, mercuric chlorid, and formalin for preserving composite milk samples. The author considers that the best results were obtained with formalin, $\frac{1}{2}$ teaspoonful being added to 1 pint of milk. Cream containing 0.25 per cent of acid and churned at a temperature of 63° F. gave a more exhaustive churning than cream containing 0.37 per cent of acid and churned at a temperature of 70°. Cream containing over 50 per cent of fat or less than 25 per cent did not churn well. The best results were obtained with cream containing 33 per cent of fat. In churning experiments with whole milk a 12-gal. barrel churn was compared with a 3-gal. dash churn. The results of 5 trials showed little difference in the 2 methods.

The dairy herd, G. H. TRUE (*Arizona Sta. Rpt. 1902, pp. 256-258*).—A monthly record is given for 6 cows for 1 year, with notes on the care and management of the herd. The yield of milk ranged from 3,931.5 lbs. to 7,319.7 lbs., and the yield of fat from 210.42 lbs. to 377.47 lbs. The record is compared with that of the previous year.

Feeding hay to cows on pasture, G. H. TRUE (*Arizona Sta. Rpt. 1902, pp. 258, 259*).—The experiment included 2 lots of 3 cows each and lasted from September 16 to January 6. From November 12 to January 6 one lot was fed 2,125 lbs. of mixed barley and alfalfa hay. The yield of butter fat from the cows pastured during the whole experiment was 16.5 lbs. less during the last 2 months than during the first 2 months of the experiment, while the cows fed hay showed a decrease of only 11.06 lbs. The difference in yield was not sufficient to pay for the hay fed. "The results of this trial should not be taken for more than they are worth, and on the strength of it the writer would not argue against the feeding of hay to cows on pasture during the colder months."

Report of the Milk Control Station in Christiania, Norway, 1901, H. OLSEN (*Aarsber. Offent. Foranstalt. Landbr. Fremme, 1901, pp. 311-313*).—During the year 44,817 samples of dairy products were tested. The average fat content of the 40,049 samples of milk was 3.46 per cent. The average fat content of the 4,409 samples of cream was 17.67 per cent.—F. W. WOLL.

Report of the Milk Control Station, Trondhjem, Norway, 1901, T. SOLBERG (*Aarsber. Offent. Foranstalt. Landbr. Fremme, 1901, pp. 316-319*).—During the year 53,436 samples were examined. The average fat content of 53,283 samples of milk was 3.52 per cent. Attention is called to the usual rise in the fat content of the milk when the cows are let out in the spring, from 3.36 per cent in May to 3.54 per cent in June.—F. W. WOLL.

Report of the Milk Control Station, Bergen, Norway, 1901, K. SEIELSTAD (*Aarsber. Offent. Foranstalt. Landbr. Fremme, 1901, pp. 319-323*).—Similar data are given as indicated under the reports of the similar stations in Christiania and Trondhjem.—F. W. WOLL.

The cause of ropy and slimy milk, J. TILLMANS, J. KÖNIG, and A. SPIECKER-MANN (*Ztschr. Untersuch. Nahr. u. Genussm., 5 (1902), Nos. 19, pp. 887-913; 20, pp. 945-961*).—The literature of this subject is reviewed and several investigations are reported. The behavior of several species of bacteria in sterilized and unsterilized milk was studied. The results showed marked differences in the earliness with which ropiness appeared and in its duration and intensity in sterilized milk inoculated with different species. The disappearance of ropiness in some cases was coincident with the appearance of a gassy fermentation. In unsterilized milk, with which similar results were obtained, the bacteria causing ropiness restrained the development of the lactic-acid bacteria. A study was made of the chemical changes taking place in milk inoculated with such bacteria. The solids were diminished largely through the decomposition of the sugar. The acidity was increased. The fat in some cases was acted upon and the casein was peptonized to some extent. Definite

conclusions were not reached in investigations concerning the formation and chemical nature of the viscous material.

Contribution to the study of the cause of slimy and ropy milk, T. GRUBER (*Rev. Gén. Lait*, 2 (1902), No. 5, pp. 97-100).—The author notes that 16 micro-organisms—10 bacilli and 6 micrococci—causing viscous and ropy milk have been isolated. The biological characteristics of a micrococcus isolated by the author from milk and designated *Coccus lactis viscosi* are reported. The organism when inoculated into milk rapidly produced ropiness and coagulated and peptonized the casein.

Milk powder, M. EKENBERG (*K. Landt. Akad. Handl. Tidskr.*, 41 (1902), No. 1, pp. 88-92).—By evaporation of whole or skim milk in vacuo at a low temperature (below the point of coagulation of albumin), the author succeeded in preparing a fine white powder which will dissolve to a milk-like solution with water of a temperature of 60 to 70° C. The powder has the flavor of milk, and its solution in water resembles milk perfectly in appearance, flavor, and taste, and in the fact that the casein in this solution is precipitated by rennet. The keeping qualities of the milk powder are stated to be good. It does not mold, ferment, turn acid or rancid, and is not hygroscopic. According to the figures given the expense of the manufacture of the powder is slightly over one-third of a cent per liter of milk. One kilogram of the powder will make about 10 liters of milk of the original concentration. The apparatus for the manufacture of the powder is simple, so that it can easily be attended to by the ordinary help in creameries. It can also be used for the evaporation of whey. Important results are anticipated from the utilization of skim milk for the manufacture of this powder, which can be used as a human food, in bread making, for puddings, and numerous other household purposes. Considerable advantage is claimed for the powder over protein foods manufactured from milk, like protene, proton, etc., both on account of lower cost of manufacture, and because the albuminoids of the milk are present in the powder in the right physiological condition for use as a food material.—F. W. WOLL.

The refractometer testing of butter and a new form of thermometer for the butter refractometer, E. BAIER (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 5 (1902), No. 23, pp. 1145-1150, fig. 1).—Determinations of the refractometer number of 10,487 samples of butter during a period of 6 years are summarized. Of the samples of butter examined from November to May, 2 per cent showed a refractometer number at 35° C. of 43, 26 per cent 44, 57 per cent 45, 11 per cent 46, and 4 per cent 47; and of the samples examined from June to October, 6 per cent showed a refractometer number of 45, 27 per cent 46, 43 per cent 47, and 23 per cent 48. The variation was less in the winter butter. Instead of an average number of 47 at 35° C., the author believes that standards of 45.7 for butter from November to May, and 47.7 for butter from June to October would be better.

Denmark's butter exports, 1901-2, B. BÖGGILD (*Tidsskr. Landökon.*, 21 (1902), No. 12, pp. 593-602).—The total imports of butter during the year ended October 30, 1902, were 49,217,101 Danish pounds (1.1 lbs. avoirdupois), and the exports 175,510,907 lbs., leaving a net exportation of 126,300,000 lbs., an increase over that of the preceding year of about 7,400,000 lbs. Of the exports 168,300,000 lbs. were sent to Great Britain, or over 10,000,000 lbs. more than during the year 1900-1901. The average quotation for high-grade butter for the year was 95.1 öre per pound (equivalent to 23.4 cts. per pound avoirdupois).—F. W. WOLL.

Swedish butter exhibits (*Landtmannen*, 13 (1902), No. 50, pp. 798-803).

Danish cooperative creameries during the past twenty years, B. BÖGGILD (*Tidsskr. Landökon.*, 21 (1902), No. 4, pp. 249-291).—A sketch of the development and present condition of the Danish cooperative creameries.—F. W. WOLL.

Trials with different systems of illumination for creameries, P. V. F. PETERSEN and K. S. KRISTENSEN (*54. Ber. Kgl. Vet. Landbohøjskoles Lab. Landökon. Forsøg* [Copenhagen], 1902, pp. 94).—In a comparative study of electric and acetylene light

for use in creameries, the authors find that considering first cost and the cost of maintenance there is but little difference in expense between the 2 systems. The cost of either of the systems of illumination will be found considerably higher than kerosene lamps, but more and better light is obtained. Discussing the objections raised against acetylene light, it is stated that the danger of explosion with a well-built apparatus which is not handled recklessly is small, and that the odor of acetylene gas does not come into consideration when the generator is properly constructed and the piping well done. Acetylene light had been used in Hedelykke creamery (Denmark) for a year and a half at the writing of this report, during which time no criticism of the butter had been made on the part of the commission men or judges, which were traceable to the system of illumination used.—F. W. WOLL.

Some of the compounds present in American Cheddar cheese, L. L. VAN SLYKE and E. B. HART (*New York State Sta. Bul.* 219, pp. 203-216).—Introductory notes are given on the different compounds formed in cheese during the process of ripening, and experimental work covering a number of years is reported. Paracasein or pseudocasein was found in all the cheeses examined. Preparations were obtained by extraction with water and precipitation with 0.2 per cent hydrochloric acid. Methods of purification further employed were not satisfactory in removing all the impurities. Elementary analyses are also given of preparations of lysatin, histidin, lysin, and putrescin (tetramethylenediamin), and the methods employed in the separation of these compounds are described. In cheese $\frac{1}{2}$ months old the authors found 3 basic products, lysatin, histidin, and lysin, and in cheese 15 months old putrescin and lysin were found. A high content of ammonia is noted as a marked characteristic of cheese ripened at temperatures above 16 to 18° C., and a usual accompaniment of a pungent flavor. The presence of free hydrogen in gassy cheese is considered easily capable of favoring the early formation of the reduction products putrescin, cadaverin, and ammonia.

"There appears to be good evidence that there is regularly in the cheese-ripening process, in the case of hard cheeses like Emmenthaler and American Cheddar, a conversion of primary into secondary amido compounds, and these chemical changes may explain, perhaps, the gradual development of flavor in normal cheese; in other words, we may find that the changing flavor of cheese, as it ages, is due, to some extent, to increasing quantities of secondary amido compounds. . . .

The subject of cheese flavors is one of complex difficulties, but it is safe to say that these flavors are due to the presence of specific compounds, and any work that shows in cheese the formation and presence of compounds capable of imparting flavors will contribute to the solution of a problem whose details are now little understood."

Statistics of dairy cows and the dairy industry (*Twelfth Census United States, Census Rpts., vol. 5 (Agriculture, pt. 1), pp. CLXV-CLXXXVI*).—The early history of dairying in the United States is briefly reviewed, and statistics are given showing the condition of the dairy industry on June 1, 1900. The total number of dairy cows on that date was 18,112,707, valued at \$537,232,246. Of this number 17,139,674 cows were on farms and ranges, and valued at \$29.68 each. The milk produced on farms and ranges in 1899 was reported as 7,266,392,674 gal., and that not produced on farms and ranges was estimated as 462,190,676 gal., making a total production of 7,728,583,350 gal. The total production of butter was 1,574,471,673 lbs., cheese 298,344,654 lbs., and condensed milk 186,921,787 lbs. The 10 most important States as regards the number of cows were in order of rank New York, Iowa, Illinois, Wisconsin, Pennsylvania, Texas, Ohio, Missouri, Minnesota, and Kansas. As regards the number of gallons of milk produced in 1899 the rank was as follows: New York, Iowa, Pennsylvania, Wisconsin, Illinois, Ohio, Michigan, Minnesota, Missouri, and Texas. With respect to the farm value of dairy produce the order was: New York, Pennsylvania, Illinois, Iowa, Wisconsin, Ohio, Michigan, Minnesota, Texas, and Missouri. With respect to the number of farms which derived their principal income

from dairy produce the order was: New York, Pennsylvania, Wisconsin, Maine, Vermont, Illinois, Massachusetts, Michigan, Ohio, and Arkansas. "From every point of view New York ranked as the leading dairy State." It is considered as proved that butter and cheese can be made with profit in most parts of North America. "Generally speaking, good butter can be made wherever good beef can be raised."

VETERINARY SCIENCE AND PRACTICE.

Studies on the phenomenon of agglutination, C. NICOLLE and M. TRENEL (*Ann. Inst. Pasteur*, 16 (1902), No. 8, pp. 562-586).—A critical review of the extensive literature of this subject is presented. The species of bacteria most studied with regard to the phenomenon of agglutination are typhoid and tubercle bacilli. The authors found as a result of their extensive experiments that the susceptibility to agglutination and the power of agglutinating are apparently properties which are inherent in all free cells, especially bacteria. Such differences in these properties, however, are to be observed that bacteria may for practical purposes be divided into species which are agglutinable and agglutinogenic, and those which are nonagglutinable and nonagglutinogenic. Both these properties appear to exist together in about the same relative proportions in different species of bacteria. The motile bacteria are much more susceptible to agglutination than nonmotile forms, and it appears probable that motility is almost necessary to the existence of pronounced power of agglutination. Another important conclusion mentioned by the authors is that the agglutinating power appears to be associated with the presence of a membrane upon the bacteria. The more marked the membrane of a given species of bacteria the more pronounced is the susceptibility to agglutination and the power of causing agglutination.

The dissociation of the agglutinating and sensibilizing properties of specific sera, A. DUBOIS (*Ann. Inst. Pasteur*, 16 (1902), No. 9, pp. 690-693).—The author conducted experiments with the blood of the common fowl. The blood when defibrinated and subjected to a temperature of 115° C. forms a mass which can not be injected. If, however, the red corpuscles are previously washed with normal salt solution for the purpose of removing other elements of the serum, the emulsion may then be heated in steam to a temperature of 115° for a quarter of an hour, with the result that a somewhat cloudy liquid is obtained, but one which can be used in making injections. During the author's experiments it was found that the serum of rabbits treated with red corpuscles from fowls after heating to a temperature of 115° C. did not contain the sensibilizing substance, but that the agglutinins were present in considerable number. It is believed, therefore, that these substances are distinct and that one may exist without the presence of the other.

The effect of absorption upon the action of alexin, M. WILDE (*Arch. Hyg.*, 44 (1902), No. 1, pp. 1-74).—This paper contains an account of experiments instituted for the purpose of determining the extent to which alexins are absorbed by various substances, and the effect of this absorption upon the bactericide action of serum. The literature of the subject is carefully reviewed in connection with a bibliography. The experiments conducted by the author included a test of the extent of absorption of alexin by dead bacteria, living bacteria, organic cells, and insoluble proteids. The serum for use in these experiments came from various species of animals, including cattle, dogs, and rabbits. The bacterial organisms which were employed were chiefly cholera vibrio and anthrax bacilli. During these experiments it was found that various substances, especially living and dead bacteria, yeast cells, red blood corpuscles, disintegrated tissue cells, and insoluble proteids, particularly aleuronat, may entirely destroy the bactericide and hemolytic action of alexin from the serum of cattle, dogs, and rabbits. The disappearance of

the active properties of these sera occurs as a consequence of the combination of the alexin with the other bodies mentioned and is in the nature of a chemical rather than a purely physical absorption. The absorption of the alexins does not depend entirely upon the quantity of the substances and the time of exposure, but also upon the temperature at which the mixtures are maintained. At a temperature of 0° C. no absorption of the alexin took place. No regeneration of alexin occurs after it has once become fixed. The absorptive power of the various substances already mentioned is not removed by heating to the boiling temperature. The experiments of the author give no support to the assumption of a plurality of alexins in the serum of one species of animal. The alexin may also be fixed inside of the animal body so that guinea pigs are destroyed by an intraperitoneal injection of a nonfatal dose of cholera or typhoid bacilli if a certain quantity of absorbing material is injected at the same time.

The rôle of the membrane of bacteria in agglutination, W. DEFALLE (*Ann. Inst. Pasteur*, 16 (1902), No. 8, pp. 595-613).—In the author's experiments a large number of the more common species of bacilli were employed. As a result of the experiments and observations made by the author it is concluded that the antibodies as well as the agglutinins, and to a certain extent the sensibilizing substances appear to be products formed in the organism as a result of resorption of the bacterial membranes. The author found that, other things being equal, the better developed the membrane around a given species of bacteria the richer it was in substance capable of producing an organic reaction and the more abundant was the production of antibodies. The bacterial organism was also more susceptible to these substances than bacteria in which the membrane was less well developed.

Variations in the effects and nature of the secretions of a pathogenic organism, CHARRIN and GUILLEMONAT (*Compt. Rend. Acad. Sci. Paris*, 134 (1902), No. 21, pp. 1240-1242).—Attention is called to the fact that inoculations with the soluble products of different pathogenic organisms vary extremely in the rapidity and intensity of their action. In the case of some organisms the effect is shown only after a period of considerable length, while with *Bacillus pyocyaneus* injurious effects may be produced within a few minutes or almost instantaneously. A study of the secretions of this organism shows that death may be produced by inoculation of its soluble products without any intervening period of incubation. The toxicity of these products is shown not to be due to the coloring matter, since the latter is even less toxic than certain organic coloring matters, such as bilirubin.

The differentiation of anaerobic bacilli, P. ACHALME (*Ann. Inst. Pasteur*, 16 (1902), No. 9, pp. 641-662).—A variety of bacterial organisms were studied, including the bacillus of tetanus, blackleg, botulism, as well as *B. enteritidis sporogenes*. The author concludes from his studies that the morphology of bacteria can not be used as a basis for differentiating the species. The motility of bacterial organisms is also of little diagnostic value. A large number of bacteria are motile at times, and those which are most actively motile are sometimes comparatively motionless. The reaction of bacteria to stains is of more value in diagnosis. Similar statements are made for the aspect of colonies of bacteria on solid media, sporulation, and especially for the assimilative functions of bacteria. The growth, absorption of material, and excretion of bacteria on various nutrient media form, according to the author, the most important criteria for differentiating species.

The physiology of spore formation in bacilli, and notes on the growth of certain anaerobic bacteria, T. MATZSCHITA (*Arch. Hyg.*, 43 (1902), No. 3-4, pp. 267-376, pls. 2).—An elaborate review of the literature of this subject is presented and detailed notes are given on the various methods which have thus far been employed for producing anaerobic conditions for the development of bacteria. The author's experiments involved tests of all the original methods, and the organisms experimented with include the bacillus of malignant edema, blackleg, anthrax, *Bacillus botulinus*, *B. sporogenes*, *B. subtilis*, and *Clostridium butyricum*.

In these experiments it was found that anaerobic bacteria developed abundantly on slant agar preparations and on the surface of plate cultures in the presence of hydrogen or any space which is free from oxygen. In the presence of oxygen anaerobic bacteria develop in mixed cultures with aerobic bacteria, but are not able to develop in the presence of dead aerobic bacteria or any filtrate from a bouillon culture of aerobic organisms. The maximum quantity of oxygen in which the growth of obligate anaerobic bacteria takes place is about 0.0031 per cent, and the minimum air pressure suitable for the growth of obligate aerobic forms appears to be exceedingly low. Bacterial organisms multiply rapidly in nutrient media. The media then becomes impoverished and finally spore formation occurs. Continued active growth under favorable conditions never brings about the formation of spores. The primary cause of spore formation is lack of nutritive material. In addition to this lack of nutritive material, oxygen plays an important part in the spore formation in bacteria. Facultative and obligate anaerobic bacteria produce spores rapidly in the presence of oxygen. The spore formation of anaerobic bacteria after the admission of air takes place rapidly under otherwise favorable conditions, even when an abundance of nutritive material is still present. Aerobic bacteria never produce spores in an atmosphere of hydrogen and under an air pressure of less than 30 mm. The formation of spores takes place most rapidly in nutrient media which are unfavorable to the growth of the bacteria in question. The optimum amount of common salt for spore formation in anaerobic bacteria is about 0.25 to 0.5 per cent, and of grape sugar 5 to 10 per cent, while the optimum temperature varies from 34 to 38° C. During the author's experiments it was found that anaerobic bacteria possess a much lower resisting power against acids than against alkalis. The formation of spores takes place more readily in a dark room than in diffuse sunlight.

Differential diagnosis of various micro-organisms belonging to the group of hemorrhagic septicemia with the help of specific serum reactions, O. VOGES (*Centbl. Bakt. u. Par., 1. Abt., 31 (1902), No. 13, Orig., pp. 645-650*).—The diseases belonging to the general group of hemorrhagic septicemia are classified by the author into 4 sections, viz., Schweinepest, hog cholera, swine plague, fowl cholera, and rabbit septicemia. It is maintained by the author that the serum reaction is normally specific for each of these diseases. It was found that no serum could be obtained which was specific for hog cholera and swine plague at the same time.

Unknown infection material, E. JOEST (*Centbl. Bakt. u. Par., 1. Abt., 31 (1902), Nos. 8, Orig., pp. 361-384; 9, pp. 410-422*).—The author reviews the literature of the subject in a critical manner, in connection with an extensive bibliography. Especial attention is given to a discussion of those diseases of which the nature of the virus is not understood. These include smallpox, foot-and-mouth disease, rinderpest, rabies, mosaic disease of tobacco, etc. A classification of infectious material is adopted in which different kinds of virus are arranged as follows: Living infectious material, including micro-organisms which may in turn be morphologically demonstrable and may be cultivated; these include bacteria, protozoa, and other vegetable and animal microparasites. This general group of micro-organisms also includes those which are not known morphologically and can not be cultivated; this subgroup includes micro-organisms which can be seen by the aid of the microscope, but have not yet been identified definitely as a cause of disease, and also micro-organisms which are so minute as to be beyond the limits of visibility under the microscope. Besides micro-organisms, the group of living infectious material includes the so-called living, fluid contagium. Chemical infectious materials are considered by the author under the head of intoxication material. It is argued that a strictly infection material and intoxication material are fundamentally different substances and that no mere toxin is capable of producing disease which can be communicated from one animal or plant to another.

Experiments in the infection of animals by means of cutaneous inoculation. E. FRITSCHÉ (*Arb. K. Gesundheitsamte*, 18 (1902), No. 3, pp. 453-474).—A critical review of the literature of this subject is presented by the author. The experiments reported in this paper were made on guinea pigs, rabbits, and mice, and the organisms used in the experiments included those of anthrax, diphtheria, plague, swine erysipelas, swine plague, fowl cholera, glanders, human and bovine tuberculosis, as well as *Streptococcus pyogenes*, *Diplococcus lanceolatus*, and *Staphylococcus pyogenes aureus*. In all the experiments a portion of the skin of the abdomen of the experimental animals was shaved so as to remove the hair and a part of outer layers of the cuticle. Care was taken not to scrape the skin to such an extent as to cause bleeding. The cultures of the pathogenic bacteria were then rubbed on the shaved areas. The general results of these experiments may be stated as follows:

All of the organisms with which experiments were made were found to be capable of infecting the experimental animals through the skin when treated in the manner just mentioned, and causing death. The course of the disease was in general longer in cutaneous than in subcutaneous inoculation. In the case of tuberculosis the course of the disease was twice as long in the first-mentioned as in the second-mentioned method of inoculation. The course traveled by the bacteria in gaining entrance to the experimental animals varied considerably. The bacilli of anthrax and swine erysipelas penetrated through the hair follicles. Some of the species of pathogenic bacteria, such as the diphtheria bacilli, did not penetrate very deeply into the skin. The organisms of plague and glanders, as well as the *Streptococcus*, gained entrance by means of the lymphatic vessels, while the organisms of swine plague and hog cholera, as well as *Diplococcus lanceolatus*, entered the experimental animals through the capillaries and the blood vessels.

A bibliography of the subject is appended to the article.

The acid-proof and alcohol-proof properties of *Streptothrix farcinica*, and the relationship of species of *Streptothrix* to the acid-proof fungi. C. FEISTMANTEL (*Centbl. Bakt. u. Par.*, 1. Abt., 31 (1902), No. 10, Orig., pp. 433-445).—In the study of *S. farcinica* on material obtained from diseased cattle, the author observed that the filaments of these organs in streaked cultures were proof against acids and alcohol, whether the original material came from pus, pure cultures on various nutrient media, or from sections of pathological material. The organisms were readily stained by the Gram method and retained some of the stain even after a long decoloration in alcohol. The formation of tubercles was observed in the lungs of guinea pigs which were inoculated by the intravenous method, within about 3 weeks after inoculation. The author discusses the behavior of this organism upon various nutrient media, in connection with a review of the literature of the subject. A bibliography of 19 titles is added to the article.

Accidents following upon vaccination, their pathogeny and prophylaxis. E. LECLAIRCHE and H. VALLEE (*Ann. Inst. Pasteur*, 16 (1902), No. 8, pp. 614-624).—The authors briefly review the history of cases in which infection has taken place as a result of vaccination against diseases, such as anthrax, blackleg, and swine erysipelas. It is argued that the process for manufacturing vaccines has been so perfected that these substances can hardly be considered dangerous or as responsible for infection in the cases which have been recorded. The greatest danger appears to lie in the careless use of virus in connection with these vaccines for the purpose of increasing the resisting power of the animal and the consequent immunity.

Report of the stock and brands branch for the year 1901. A. SALWEY, R. D. JONES, and J. D. STEWART (*New South Wales, Dept. Mines and Agr., Stock and Brands Branch Rpt.* 1901, pp. 29).—In this report notes are given on the inspection work, number of horses, cattle, sheep, pigs, and dogs, and on the most prevalent diseases in New South Wales during the year covered by the report. The chief diseases of

horses were ophthalmia, influenza, and Australian stringhalt. The most important diseases of cattle were pleuro-pneumonia, blackleg, actinomycosis, tuberculosis, and Texas fever. The chief diseases observed in sheep were scab, anthrax, foot rot, fluke worms, and lung and stomach worms. The best results in the treatment of lung and stomach worms were obtained from the use of arsenic and acid drench and turpentine. A special station has been established, in which many cattle are maintained for the purpose of furnishing blood for inoculating cattle which are susceptible to Texas fever.

Annual report of the imperial bacteriologist for the year 1901-2, A. LINGARD (*Calcutta: Supt. Govt. Printing, India, 1902, pp. 15*).—During the year covered by this report 50,000 doses of anti-rinderpest serum were prepared by a veterinarian. The serum was prepared by both the slow and rapid methods. By the latter method the serum may be ready for use in 21 days, while by the slow method 80 days are required. It is recommended that cattle under 3 years of age should not be utilized in the preparation of serum, since they yield a serum of much lower protective power than older animals. Detailed notes are given on the results obtained from the use of this serum in different parts of India. Experiments with this serum in protection of buffaloes showed that 5 cc. of the serum per 600 lbs. live weight was sufficient to render the animals immune.

Notes are also given on the prevalence of anthrax in India. In the preparation of protective anthrax serum the author's experiments showed that the inoculation disease runs a course of from 70 to 144 hours in plains cattle and one of from 35 to 120 hours in hill cattle. The hill cattle are much more susceptible to anthrax than those of the plains. Brief descriptive notes are also given on the occurrence of epizootic lymphangitis, surra, strangles, paralysis, and influenza.

Annual report of the veterinary service for the year 1901 (*Jour. Khediv. Agr. Soc. and School Agr., 4 (1902), No. 3, pp. 112-116*).—Brief notes are given on the occurrence of foot-and-mouth disease, anthrax, sheep pox, rabies, glanders, contagious pleuro-pneumonia, barbone, and cattle plague. It is said that barbone is a rapidly fatal disease which occurs chiefly during the low and rising period of the Nile; most cases have apparently been traced to animals drinking water from stagnant pools.

A discussion of the relationship of human and bovine tuberculosis, J. D. HAMILTON ET AL. (*British Med. Jour., 1902, No. 2178, pp. 944-948*).—A critical review is given of the experimental facts upon which Koch based his conclusions, in which the identity of human and bovine tuberculosis was denied. It is argued that in some of Koch's experiments where the issue was considered doubtful other investigators might have considered the cases as positive infections with tuberculosis. Attention is called to the great variation in the virulence of tubercle bacilli under different conditions. The authors propose the following criterion for determining whether or not an infection has taken place: If it is found that inoculated virus has died at the point of inoculation and failed to produce tubercles in other parts of the body, the result must be considered negative. If the bacillus is found only in the local lesion at the point of inoculation and has increased some in numbers the case may be considered doubtful. If, however, the bacillus is found in the local lesion in a cheesy abscess and if the adjacent lymphatic glands show a tuberculous structure, the case must be considered as proving the fact of infection.

The question of the identity of human and bovine tuberculosis, A. von SZÉKELY (*Centbl. Bakt. u. Par., 1. Abt., 32 (1902), Nos. 6, Ref., pp. 167-173; 7, pp. 193-293; 8, pp. 225-237*).—The author presents a review of the literature bearing on this subject which has been published since Koch's address before the congress on tuberculosis in London. The experiments and conclusions of Koch are outlined and explained in detail and especial attention is given, in a review of the literature of the subject since Koch's address, to classification of the various articles with reference to their bearing on this question. The literature of German, French, English,

American, and Italian authors is reviewed with considerable detail and with apparent fairness. At the conclusion of the author's special criticism of these various articles it is stated that the main question at issue regarding the identity of tuberculosis in man and cattle is still unsettled.

The British Congress on Tuberculosis, G. T. BROWN (*Jour. Bath and West and Southern Counties Soc. [England]*, 4. ser., 12 (1902), pp. 41-52).—A brief review of the more important papers which were read at this congress. The author expresses the belief that tuberculosis may be effectively combated in both man and animals.

On tuberculosis in cattle with special reference to the virulence of the milk of tuberculous cows, E. J. McWEENEY (*Jour. Dept. Agr. and Tech. Instr., Ireland*, 2 (1902), No. 4, pp. 663-675).—The author reviews the question of the infectiousness of the milk of tuberculous cows in connection with a bibliography of 34 titles. In his opinion it is desirable that tuberculous cows be divided, for purposes of experimentation and discussion, into 3 classes: Those which show clinical symptoms of tuberculosis, those which are affected with tuberculosis of the udder, and those which react to tuberculin but show no clinical symptoms of the disease. The author's experiments were made with 5 cows of the third class. It is believed that more than half of all the cows of Germany and Great Britain belong to this class. The udders of the 5 cows were carefully cleaned before milking, and after the milk was collected it was passed through a centrifuge; the sediment collected at the bottom was then used for inoculating guinea pigs, a quantity of the cream being inoculated into the opposite side of each experimental animal at the same time. The total number of experiments thus performed was 23, and no case of tuberculosis developed in the experimental animals. Seven other animals were inoculated with mixed milk from tuberculous animals, with the same result. The results of these experiments are in accord with those of Ostertag, who was likewise unable to find tubercle bacilli in the milk of cows which merely reacted to tuberculin but which did not give evidence of clinical symptoms. The method of combating tuberculosis recommended by the author is the system devised by Bang.

The nature of the tuberculin reaction, K. PREISICH and P. HEIM (*Centbl. Bakt. u. Par., 1. Abt.*, 31 (1902), No. 14, Orig., pp. 712-734).—The recent literature relative to tuberculin tests is reviewed in connection with a bibliography of the subject. Experiments were instituted for the purpose of obtaining evidence on the question whether the tuberculin reaction absolutely required the presence of tuberculosis in the experimental animals, and whether the presence of products of the tubercle bacillus was necessary in order to obtain a reaction to tuberculin or whether other substances formed under the influence of the tubercle bacillus could give rise to a reaction to tuberculin.

The first experiments were with guinea pigs, but it was found that the body temperature in these animals varied too greatly. Rabbits were found to maintain a more constant temperature in health and were therefore chosen as more suitable for the purposes of these experiments. One series of experiments was conducted during which collodion sacs containing cultures of tubercle bacilli were placed in the peritoneal cavity of healthy rabbits. This operation was found to be a difficult one, since the collodion sacs were frequently ruptured and the animals thus became infected with tuberculosis. In the few cases in which the operations were successful and typical reaction to tuberculin occurred without the presence of an infection of tuberculosis in experimental animals, this reaction is explained as being due to some substance produced by the growth of the tubercle bacilli in the collodion sacs and subsequently distributed in the experimental animals by diffusion through the collodion sacs.

Another long series of experiments was undertaken on rabbits during which the action of tuberculin in connection with other materials was tested. The materials used along with the tuberculin included tuberculous glands, spleen, liver, and other

organs, blood serum of tuberculous and healthy guinea pigs and children, and similar tuberculous and nontuberculous material preserved in salt solution. As a result of these experiments, it was found that the pure blood serum of healthy guinea pigs together with tuberculin caused an elevation of temperature in healthy rabbits in a large percentage of cases. When the blood serum was preserved in salt solution, the elevation of temperature was more constant and more pronounced. The blood serum of healthy children, together with tuberculin, caused an elevation of temperature only when it was preserved in salt solution. Pure blood serum of tuberculous guinea pigs, together with tuberculin, when injected into healthy rabbits invariably caused a rise of temperature, while the pure blood serum of tuberculous children, together with tuberculin, caused a rise of temperature in a number of cases, and this elevation of temperature was more pronounced when the material was preserved in salt solution.

The authors draw the following conclusions from these experiments: Tuberculin is a reliable diagnostic agent for tuberculosis, but its value in differential diagnosis is much less. Reaction to tuberculin may be obtained in consequence of the presence of other pathological processes than tuberculosis, and this appears to be especially true for man. In veterinary practice tuberculin is considered a valuable reagent in cases where it is necessary to determine whether an apparently healthy animal is tuberculous or not. It appears to be desirable, however, in making tuberculin tests to observe carefully the symptoms of the animal before injecting the tuberculin and to have a record of variations in temperature for a number of days previous to the inoculation.

Concerning bacilli which resemble those of tuberculosis and the bacilli of smegma. A. WEBER (*Arch. K. Gesundheitsamte*, 19 (1902), No. 2, pp. 251-283, pls. 5).—A review of the literature of this subject is presented in connection with an extensive bibliography from 1882 to 1902. The organisms belonging to the class of acid-fast bacteria are divided by the author into 3 groups: The first group contains the nearest relatives of the human tubercle bacillus (viz, the bacilli of bovine and avian tuberculosis and bacilli found in fish and other cold-blooded animals); the second group contains bacilli of a saprophytic nature, which have received various names according to the material in which they are found; the third group includes smegma bacilli. The author confined his attention during the experiments reported in this paper to the second and third groups. The subject matter of the author's report on the second group includes a discussion of the origin, distribution, differentiation, diagnosis, cultural and morphological characters, staining reactions, and effect upon the animal body, of this group of bacilli. Emphasis is laid on the necessity of exercising particular care in making cultures from suspicious material in order to avoid confusing acid-fast bacilli of nonpathogenic nature with virulent tubercle bacilli, which they closely resemble in almost every respect except virulence. It has been asserted by some investigators that these acid-fast bacilli may produce pathological effects which closely resemble those of tuberculosis. The author therefore undertook a number of experiments in inoculating guinea pigs, rabbits, mice, chickens, and pigeons with these organisms. In none of the experiments was there any pathological process established which possessed a progressive character and which involved all of the internal organs. The bacteria with which experiments were made, however, appeared to exercise a pathogenic action to a certain extent. The effect of these bacilli, however, appears not to be in the nature of a true infection, but rather that of a foreign body. During the experiments in subcutaneous inoculation of guinea pigs it was found that the organisms did not remain at the point of inoculation and in the neighboring lymphatic glands but were carried into the internal organs, presumably through the agency of phagocytes. In the latter situation the organisms may produce slight alterations of the tissue. Small yellowish foci were found in the liver of the animals 4 months after inoculation. From

this material bacteria were again obtained in pure cultures. Close observation of the conditions, however, shows that the number of organisms present in inoculated animals gradually diminishes.

Combating tuberculosis in hogs by means of tuberculin tests, THIRO (*Deut. Thierärztl. Wchnschr.*, 10 (1902), No. 12, pp. 113-116).—Fatal epizootics were observed by the author in a number of herds of pigs. In such outbreaks many young sucking pigs were fatally affected, and the owners of the herds were finally prevailed upon to permit the general application of the tuberculin test to the brood sows. During these experiments it was found that the normal temperature of hogs varied from 37.6 to 40.6° C. in different animals, with an average of about 39.8° C. In a number of pigs tuberculosis could be diagnosed from external symptoms without the tuberculin test. Tuberculin injections, however, were made without reference to the extent of the disease. According to the author's observations tuberculosis was found in a number of forms, including alimentary tuberculosis with gradual emaciation, anemia, arched back, pulmonary tuberculosis with short, dry cough and rapid breathing, and cerebral tuberculosis accompanied with spasms, paralysis, and falling fits. The rise of temperature in tuberculous pigs after tuberculin injection ranged from 1½ to 3° C. The author considers that a rise of 1° C. is necessary in order to be sure of the presence of tuberculosis. In adjusting the amount of tuberculin to the size or age of the hog, the author found it desirable to disregard the size and administer doses according to age. The following doses are recommended: For pigs 4 months old, 0.1 cc.; 9 months old, 0.15 cc. to 0.2 cc.; 18 months old, 0.25 cc.; older animals, 0.3 cc. Of the 87 hogs which were inoculated 24 reacted, and of these 24, 21, or 88 per cent, were found to be tuberculous.

Observations on the electrical resistance and index of refraction of tetanus toxin, DONGIER and LESAGE (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 6, pp. 329, 330).—During a series of experiments with cultures of tetanus bacillus it was found that when this organism was cultivated in bouillon the electrical resistance of the medium was somewhat reduced. This effect persisted after the bacilli had been removed by filtration. It appears, therefore, that the diminution in electrical resistance is due to changes produced in the medium by the growth of the tetanus bacillus. No characteristic differences in the index of refraction were observed in media in which tetanus bacillus was growing or in the same material after boiling.

The disappearance of anthrax bacilli in normal lungs, J. J. SNEEL (*Ztschr. Hyg. u. Infektionskrankh.*, 40 (1902), No. 1, pp. 103-133).—A critical discussion of the literature of this subject is given in connection with a bibliography of 50 titles. The author's experiments were designed to obtain evidence in the question of frequency of infection of normal lungs by bacteria floating in the atmospheric air. At first experiments were made with a Pravaz syringe which was inserted between two rings of the trachea. It was found, however, that an infection took place in every case through the wound. Experiments of a similar nature were tried after exposing a portion of the trachea and burning an opening with a small needle. The same results occurred as with the first-named method. The attempt was then made to introduce cultures in gelatin tubes, leaving the tubes in the opening in the trachea. It was believed that infection by the previous methods had taken place while the needle or syringe was being removed. In experiments with the gelatin tubes, however, the wound infection regularly took place. The experimental animals in these and the succeeding experiments were guinea pigs, and the organism with which the experiments were made was the anthrax bacillus obtained from a case of malignant pustule in man. When it appeared certain that satisfactory experiments could not be made by injection directly through the trachea, anthrax bacilli were injected into the upper end of the trachea through the mouth, care being exercised not to cause any injury to the mucous membrane. It was found that all possible precautions must be exercised even in the application of this method to prevent abrasion of the mem-

brane of the mouth or trachea. In the cases in which no lesion of the mucous membrane was produced, no infection of anthrax took place. In all, 20 guinea pigs were inoculated into the lungs, and 8 of them were allowed to live for a week or longer after inoculation. The experimental animals were killed at different periods after inoculation. It was found that the virulence of the anthrax bacilli was still of normal strength after 1 hour. After being 4 hours in the lungs of the guinea pigs, however, the bacilli showed changes of form and had lost the power of growth. It appeared that they had become so weakened by remaining for a short time in the lungs that they had no power of development upon artificial nutrient media. As a rule, some evidence of pneumonia was observed in the lungs. Similar experiments with anthrax spores showed clearly that the spores also are destroyed by being left in the lungs. Animals which were allowed to live recovered permanently from the temporary bad effects of the inoculation.

It is concluded from these experiments, therefore, that in the normal lungs of guinea pigs anthrax bacilli are destroyed, although these animals always died if the anthrax bacilli obtained entrance into the subcutaneous tissue.

Immunization against anthrax with pyocyanase, and combinations of this enzym, K. VAERST (*Centbl. Bakt. u. Par., 1. Abt., 31 (1902), Nos. 7, Orig., pp. 293-317; 8, pp. 348-355*).—The author reviews the literature of this subject in a critical manner, in connection with a bibliography of 67 titles. An account is given of the various methods which have been used in producing immunity in various domesticated animals against anthrax. Since it had been demonstrated that the enzym from *Bacillus pyocyanus*, commonly called pyocyanase, exercised an immunizing action against anthrax, numerous experiments were made with this substance to determine its relative value and the conditions under which it was most effective. The author conducted a large series of experiments in the laboratory, outside of the animal body and in the animal body. The experiments with animals included simultaneous injection of pyocyanase and anthrax bacillus; immunizing experiments with aqueous solution of pyocyanase in the proportion of 1 to 10; immunizing experiments with pyocyanase and immune proteids obtained from the serum and from the spleen; and immunizing experiments with pyocyanase solution and dead anthrax bacilli. The results of these experiments upon different experimental animals are recorded in detail. As a result of the experiments it is concluded that pyocyanase exercises, not only a restraining influence upon the development of anthrax cultures, but may actually dissolve the bacteria. In making simultaneous injections of anthrax cultures and pyocyanase the development of anthrax in the animal body may be checked. It was not found possible to immunize rabbits against anthrax by means of an aqueous solution of pyocyanase. The author succeeded, however, in immunizing rabbits with pyocyanase serum.

Texas cattle fever and salt sick, C. F. DAWSON (*Florida Sta. Bul. 64, pp. 519-550, figs. 3*).—A general account is presented of the cause, symptoms, post-mortem appearances, and historical pathology of Texas fever, together with notes on the life history of the cattle tick, means of exterminating the tick, and methods of immunization of cattle by tick infestation and by blood inoculation. The author believes that the best way to prevent Texas fever in native animals is to infest them mildly with ticks in early life. Medical treatment of Texas fever is usually without results in acute cases. In chronic cases the author had good results from the use of a condition powder containing 8 oz. linseed meal, 4 oz. powdered fenugreek seed, 3 oz. ginger root, 4 oz. common salt, 2 oz. hyposulphite of soda, and 1 oz. sulphate of iron. The different substances were mixed together and the dose given was a handful in bran night and morning.

The author investigated a number of cases of so-called salt sickness, and found that this disease may affect cattle at any age, but more frequently attacks calves and yearlings. In all cases of this disease which were investigated the organism of Texas fever

was found in the red blood corpuscles. It is believed therefore that salt sickness is really a chronic form of Texas fever, in which excessive infestation of ticks and poor pasture may result in producing an unusual degree of emaciation. It is believed that salt sickness may be the same as the so-called wasting disease which was investigated in Jamaica.

Texas fever, I, G. E. NESOM (*South Carolina Sta. Bul. 72, pp. 23*).—Brief popular notes are given on the subject of Texas fever, including the following points: The introduction, history, distribution, cause, method of infection, and period of incubation of this disease, together with a discussion of susceptibility, favorable conditions, symptoms, post-mortem appearances, treatment, prognosis, dipping of cattle, and preventive vaccination. From circulars sent to stock raisers in the State it was found that among 3,408 cattle mentioned in answers to the letters, 1,885 or 55.3 per cent were infested with cattle ticks, while the remainder were entirely free from them. Attention is called to the importance of these facts in the development of Texas fever.

Report upon Texas fever or red water in Rhodesia, C. E. GRAY and W. ROBERTSON (*Cape Town: Argus Printing and Pub. Co., Ltd., 1902, pp. 27, pls. 22*).—An account is given of the history of Texas fever in Rhodesia. The origin of the first cases of Texas fever in this province is not definitely known. During the past 10 years the country has become gradually infected until the epizootic proportions of the seasons of 1901 and 1902 were reached. Texas fever in Rhodesia appears, according to the observations of the authors, to differ from the same disease in other countries in the severity of infection, in the fact that very young calves on infected fields contract the disease and die, and also in the facts that 1, 2, or even 3 attacks do not confer immunity and that about 30 per cent of the cases exhibit serious lesions in the lungs. The symptoms of typical and atypical cases are described in detail. In all these cases the disease ran a virulent course, but in atypical cases the lungs are seriously affected. They become heavy and darker in color than normal, and are filled with fluid and froth. Just before death in such cases large quantities of albuminous froth are discharged from the nose. Extensive experiments in the use of a drench containing 1 dr. calomel, 1 dr. carbolic acid, 2 dr. quinine, and 1 pt. linseed oil showed that this remedy is of little value. Inoculation experiments also gave unsatisfactory results. It was found that the virulence of the blood of recovered animals varied greatly and in many instances was fatal when inoculated in small doses. It was also found impossible to protect inoculated animals during the period required for the production of immunity. Many such animals, therefore, died from the combined effects of inoculation and excessive tick infestation. Even in cases where the reaction from inoculation was typical and where the animals recovered within the usual length of time, the immunity seemed to be of variable duration and in many cases was not sufficient to protect the inoculated animals. It is apparent, therefore, that the methods which have been used in America and Australia in immunizing cattle against Texas fever can not be used at present without modification in Rhodesia. Further experiments will be made along this line and experiments are already in progress in devising effective dips for destroying the ticks. The authors recommend the use of a dip containing 6 lbs. arsenic, 24 lbs. soap, 24 lbs. washing-soda crystals, 5 gal. Stockholm Archangel tar, and 400 gal. of water.

Red water in Rhodesia, H. WATKINS-PITCHFORD (*Agr. Jour. and Min. Rec. [Natal], 5 (1902), No. 11, pp. 341-347*).—An outbreak of the disease was observed in cattle imported into Rhodesia and an examination of the disease showed that it was identical with that known as red water in Natal. The outbreak is attributed to the presence of an unusual number of ticks and the introduction of a number of animals possessing an extreme degree of susceptibility. For the purpose of preventing the further spread of the disease it is recommended that the introduction of stock from Rhodesia into Natal be prohibited until the disease has been checked. It is not con-

Rabies, or hydrophobia, W. ROBERTSON (*Agr. Jour. Cape Good Hope*, 21 (1902), No. 4, pp. 307-314).—Rabies is said to have appeared first in South Africa at Port Elizabeth, where it was quickly exterminated. The country has recently become reinfected, however, on account of the large number of dogs which are kept by natives to the north of the English provinces. Notes are given on the cause, symptoms, and treatment of this disease.

Rabies, S. B. WOOLLATT (*Agr. Jour. and Min. Rec. [Natal]*, 5 (1902), No. 15, pp. 461-466).—On account of the recent appearance of rabies in Rhodesia the author presents brief notes on the symptoms, period of incubation, and post-mortem appearances of the disease, together with an account of a method of protective inoculation against it.

Roup, F. C. HARRISON (*Ontario Agr. Col. and Expt. Farm Bul.* 125, pp. 16, figs. 10).—A general account is presented of the economic importance, symptoms, course, and treatment of this disease. A number of experiments and observations were made by the author, during which it was shown that roup could be communicated from diseased to healthy fowls by association in the same pen, or as the result of rubbing pathological membranes from diseased birds upon the mucous membranes of healthy birds. In the study of the bacteriology of roup it was found exceedingly difficult to isolate any organism which would produce the symptoms of roup when inoculated in healthy fowls. After fruitless experiments extending over a period of 4 years an organism was isolated which causes roup. The author has named this organism *Bacillus cacosmus*. The bacillus in question is frequently associated with other organisms in the form of a mixed infection. The author does not think it possible, therefore, to devise a practical treatment by serum. Notes are given on a number of curative methods which have been tried, including the use of boracic acid, corrosive sublimate, permanganate of potash, etc.

Fowl typhoid, C. CURTICE (*Rhode Island Sta. Bul.* 87, pp. 10).—An outbreak supposed to be fowl cholera was reported in a number of flocks of poultry in the fall of 1901. In one case an outbreak occurred among 2,000 chickens and resulted in the death of 25 per cent. A bacteriological investigation of material obtained from these cases was made by Dr. Theobald Smith, and the present bulletin is partly based upon his notes. The spleen of fowls affected with the disease was somewhat enlarged, and the specific organism was found in the spleen, associated also with *Bacillus coli communis*. The organism of the disease is a short, oval, nonmotile rod, which gives no indol reaction. Experiments with animals showed that rabbits and chickens were susceptible to the disease, but that guinea pigs were apparently refractory. The disease was successfully transmitted to hens by feeding pure cultures, and also by feeding the viscera of diseased hens. The organism is said to differ decidedly from that of fowl cholera. Chickens affected with the disease usually die within 2 weeks after the attack. A diagnosis is difficult or impossible without a bacteriological study. No medical treatment is effective. Sanitary measures are recommended, including isolation of diseased fowls and the use of disinfectants. It is recommended that a plan of rotation of crops be adopted and that the chicken houses be moved from place to place in accordance with this plan.

Vaccination against pasteurelloses, J. and M. LIGNIÈRES (*Compt. Rend. Acad. Sci. Paris*, 134 (1902), No. 20, pp. 1169, 1170).—An extensive series of experiments was made in immunizing horses to typhoid fever and pneumonia, fowls and rabbits to fowl cholera, dogs to distemper, and cattle and sheep to hemorrhagic septicemia. About 70,000 sheep were vaccinated against the last-named disease. In attenuating the organism the author made use of cultures which had been maintained on artificial media for about 500 generations. The first vaccine was obtained from cultures subjected to a temperature of from 42 to 43° C. for 5 hours, while the second vaccine came from cultures subjected to the same temperature for 2 hours. It was found that $\frac{1}{2}$ cc. is sufficient to vaccinate dogs, while $\frac{1}{2}$ cc. was required for calves and pigs, and $\frac{1}{4}$ cc. for cattle and horses. Vaccinated animals resisted infection from inoculation which was fatal to the control animals.

The production of a polyvalent preventive and curative serum for treatment of the pasteurelloses, LIGNIÈRES and SPITZ (*Compt. Rend. Acad. Sci. Paris*, 134 (1902), No. 23, pp. 1371-1373).—Attention is called to the fact that preventive serum treatment has been successfully devised in the case of fowl cholera, swine plague, and other diseases belonging to this class. A monovalent serum prepared from a single species of these organisms operates as a preventive and curative for all of the diseases of this class. By a series of experiments conducted with horses the author determined that immunizing products could be obtained from these animals, after being subjected to inoculation with virus of several kinds, and that this serum was effective in subcutaneous doses of 5 to 10 cc.

Liver disease (tuberculosis) of poultry, A. MEEK (*Jour. Bd. Agr. [London]*, 9 (1902), No. 2, pp. 189-192).—Notes are given on the distribution, symptoms, post-mortem appearances, etiology, and methods of prevention of tuberculosis of fowls. It is believed that the present great prevalence of this disease is partly due to ignorance as to its nature and consequent indifference as to means of controlling it.

Sorghum poisoning, H. TRYON (*Queensland Agr. Jour.*, 11 (1902), No. 4, pp. 282, 283).—Brief notes are given on the finding of prussic acid in sorghum, especially in young plants. A short abstract is also presented of an article on cyanogenesis in plants, by W. R. Dunstan and T. A. Henry.

Grazing in orchards sprayed with poisonous washes (*Jour. Bd. Agr. [London]*, 9 (1902), No. 2, pp. 193-195).—Spraying experiments were conducted for the purpose of testing the question of the possibility of stock poisoning as the result of using arsenical and other insecticides and fungicides. Two acres of young fruit trees were sprayed with Paris green, the grass between the trees being sprayed as well. A number of sheep were allowed to graze on this grass and no evidence of any injurious effect was observed.

The bactericidal and disinfecting action of Lysoform, O. SEYDEWITZ (*Centbl. Bakt. u. Par., 1. Abt.*, 32 (1902), No. 3, Orig., pp. 222-234).—Lysoform is said to consist of formalin, soap, and a small quantity of ethereal oil dissolved in alcohol. The author tested its bactericide power on a number of bacteria, including the organisms of typhoid, anthrax, cholera, diphtheria, puerperal fever, and also *Staphylococcus pyogenes aureus*. Lysoform was found to be a valuable disinfectant. It requires, however, more time to produce its effects than many other well-known disinfectants. In the case of anthrax spores growth was prevented by subjecting these organisms to a 1:1500 solution of Lysoform for a period of 8 days. However, a culture of anthrax bacillus in bouillon was not destroyed during a period of 8 days, except when exposed to a concentration of 1:100 of Lysoform.

The bactericidal action of soaps, D. KONRADI (*Arch. Hyg.*, 44 (1902), No. 2, pp. 101-112).—A test was made of the disinfecting power of a number of soaps with regard to certain species of pathogenic bacteria, especially anthrax bacillus. It was found that certain soaps, especially those which contain certain odorific materials, were complete disinfectants. As a test of this problem the author smeared anthrax cultures on the hands and then washed the hands with so-called Resorcin soap with the result that all of the anthrax bacilli were destroyed.

AGRICULTURAL ENGINEERING.

Irrigation, F. H. NEWELL (*Twelfth Census United States, Census Rpts.*, vol. 6 (Agriculture, pt. 2), pp. 799-880, pls. 9, figs. 35).—The history of irrigation in America is briefly reviewed; the present area of irrigated land, extent and measurement of the water supply, planning and construction of irrigation systems, methods of irrigation, pumping, drainage, waste of water, duty of water, and alkali are discussed; and general statistics of irrigation in the various States and Territories in the arid and humid regions are given.

"Exclusive of the rice-producing States, the Territory of Hawaii, and Indian reservations, the number of irrigators in the United States in 1899 was 108,218, an increase of 54,082, or 100 per cent, over the number reported in 1889. The number of acres irrigated was 7,539,545, an increase during the 10 years of 3,908,165, or 107.6 per cent. Of the total irrigated area, 5,944,412 acres were in crops, and the total value of the products therefrom was \$86,860,491. The total cost of construction of the irrigation systems operated in 1899 was \$67,770,942. . . . In the number of irrigators California stands far ahead of any other State, having about one-fourth of the total number in the United States. Colorado, however, exceeds in the number of acres irrigated, although not in the value of irrigated crops."

Of the total irrigated area, 7,093,629 acres were watered from streams, and 169,644 acres from wells. The number of acres in crops irrigated in 1899 was 5,711,965, and the number of irrigated acres in pasture and unmatured crops was 1,551,308. The value of the irrigated crops was \$84,433,438. . . . Of the irrigated area, 7,263,273 acres was in the arid States, 273,117 acres in the semiarid region, and 3,155 in the humid region.

Problems in farming by irrigation, S. AVERY (*Agriculture [Nebraska]*, 1 (1903), No. 11, pp. 9-12).—A brief discussion of questions relating to water rights, distribution of water, alkali, etc.

Irrigation on a Sussex farm (*Country Life [London]*, 12 (1902), No. 311, pp. 797-799, figs. 5).—Describes a method of irrigating grass and grain by means of a 10-in. centrifugal pump driven by steam, the water being delivered through 10-in. canvas hose.

Irrigation on the Burdekin Delta (*Queensland Agr. Jour.*, 12 (1903), No. 1, pp. 49-59, pl. 1, fig. 1).—The possibilities and present development are discussed.

Prospect for irrigation on the Colorado River, F. H. NEWELL (*Forestry and Irrig.*, 9 (1903), No. 2, pp. 72-74).

Completion of the Nile dams, J. WARD (*Cassier's Mag.*, 23 (1903), No. 4, pp. 549-551, figs. 10).—Descriptions of the Assiout and Assuan dams.

Projects for water conservation, irrigation, and drainage in New South Wales, H. G. MCKINNEY (*Jour. and Proc. Roy. Soc., New South Wales*, 35 (1901), pp. 223-242).—A number of proposed systems of water supply and conservation are discussed.

A simple home-made water lift, A. H. BENSON (*Queensland Agr. Jour.*, 12 (1903), No. 1, pp. 45, 46, pl. 1).

Agricultural implements in France, R. P. SKINNER (*Amer. Inventor*, 10 (1903), No. 6, pp. 91-93, figs. 11).—Descriptions are given of some of the types of machines and implements in common use in France and suggestions are made as to how American manufacturers may increase their trade there, especially by giving more attention to adapting their machines and implements to the limitations and distinctive features of continental methods.

On official trials of farm machinery, F. BOKELMAN (*Tidsskr. Landökon.*, 21 (1902), No. 5, pp. 297-331).

Trials of agricultural machinery in Ultuna (*Landmannen*, 13 (1902), Nos. 48, pp. 761-767; 49, pp. 777-779; 50, pp. 805-807; 51, pp. 814-818).

On the application of electricity in agriculture, C. V. BIRK (*Tidsskr. Landökon.*, 21 (1902), No. 7, pp. 413-452).

The technical machine testing station of the Institute for the Fermentation Industries in Berlin (*Deut. Landw. Presse*, 30 (1903), No. 9, pp. 68, 69, fig. 1).—A brief note on the equipment and work of this station.

Equipment and processes employed in agricultural operations, A. HIDIEN (*Rapport sur le matériel et les procédés des exploitations rurales. Exposition Universelle Internationale de 1900, group 7, class 55. Min. Com., Ind., Postes, et Télégraphes, France*, 1902, pp. 492, figs. 100).—This includes reports on the exhibits made at the Paris Exposition of 1900 of agricultural implements and machinery, by the author; in veterinary science and farriery, by A. Lavalard, and in fertilizers, by H. Joulie.

Granaries of the General Transportation Company of Paris, F. MAIN (*Jour. Agr. Prat.*, n. ser., 5 (1903), No. 4, pp. 118-120, figs. 2).—Describes granaries arranged so as to secure mechanical stirring of the grain, constructed on the same principle as those previously noted (E. S. R., 14, p. 196).

MISCELLANEOUS.

Thirteenth Annual Report of Arizona Station, 1902 (*Arizona Sta. Rpt. 1902*, pp. 233-270).—This includes the organization list, a financial statement for the fiscal year ended June 30, 1902, and reports of the director and heads of departments noted in part elsewhere.

Fifteenth Annual Report of Indiana Station, 1902 (*Indiana Sta. Rpt. 1902*, pp. 24).—This contains the organization list and reports of the director and members of the station staff. A list of station publications issued during the year, acknowledgments, and a financial statement for the fiscal year ended June 30, 1902, are included.

Fifteenth Annual Report of New York Cornell Station, 1902 (*New York Cornell Sta. Rpt. 1902*, pp. XLIII-433).—The report proper includes the organization list of the station, brief reports of the director and heads of departments, and a financial statement for the fiscal year ended June 30, 1902. Appendix I contains reprints of Bulletins 194-202 of the station on the following subjects: The Hessian fly—its ravages in New York in 1901 (E. S. R., 13, p. 572), further observations upon ropiness in milk and cream (E. S. R., 13, p. 686), fourth report on potato culture (E. S. R., 13, p. 734), investigations concerning the germicidal action in cow's milk (E. S. R., 13, p. 783), orchard cover crops (E. S. R., 13, p. 951), separator skimmed milk as food for pigs (E. S. R., 13, p. 1079), muskmelons (E. S. R., 14, p. 40), buying and using commercial fertilizers (E. S. R., 14, p. 23), and trap lanterns, or "moth-catchers" (E. S. R., 14, p. 272). Appendix II contains a detailed financial statement for the fiscal year ended June 30, 1901. Appendix III contains a circular of information on the reading course for farmers; reprints of Reading Lessons for Farmers' Wives Nos. 3-5; Home Nature Study Course Nos. 16-24; nine numbers of the Junior Naturalist Monthly issued during 1901 and 1902; and a syllabus of lectures on nature study.

Annual report of the director, H. P. ARMSBY (*Pennsylvania Sta. Bul. 61*, pp. 12).—The different lines of station work are briefly outlined, mention is made of needed equipment, and the income of the station from different sources is compared with that of a number of other stations.

Fifteenth Annual Report of South Carolina Station, 1902 (*South Carolina Sta. Rpt. 1902*, pp. 20).—This includes the organization list of the station, a financial statement for the fiscal year ended June 30, 1902, departmental reports, and a brief synopsis of the bulletins issued during the year. The report of the chemist contains a summary of the analyses of fertilizers inspected during 1901 and 1902.

Crop Reporter (*U. S. Dept. Agr., Division of Statistics Crop Reporter*, 4 (1902), Nos. 7, 8; 4 (1903), No. 9, pp. 8 each).—These numbers contain statistical information on the condition of crops in the United States and foreign countries. No. 7 includes a report on crop conditions in the different States and Territories on November 1, 1902. No. 9 includes a letter from the Secretary of Agriculture to Congress upon the advisability of consolidating with the Weather Bureau the work of gathering reports and statistics of crops. Consolidation is considered inadvisable.

Statistics of agriculture (*Twelfth Census United States, Census Rpts.*, vols. 5 (*Agriculture*, pt. 1), pp. CCXXXVI+767, pls. 19; 6 (*Agriculture*, pt. 2), pp. 880; pls. 19).—Part 1 deals with farms, live stock, and animal products, and part 2 with crops and irrigation. The statistics relating to special lines of agriculture are noted elsewhere in this issue. The agricultural progress in the United States during the last 50 years

is reviewed. The number of farms in 1850 was 1,449,073, and in 1900, 5,739,657. The census shows a total value of farm lands and buildings in 1900 of \$16,674,690,247, of which 21.4 per cent was in buildings. The farms are classified by area, principal source of income, value of products of 1899 not fed to live stock, tenure, and by color or race of farmer. Of the total number of farms, 3,806,414 contained each 50 acres or over. Of the total number, 54.9 per cent was operated by owners, 22.2 per cent by share tenants, 13.1 per cent by cash tenants, 7.9 per cent by part owners, 0.9 per cent by owners and tenants, and 1 per cent by salaried managers or overseers. White farmers operated 86.6 per cent of the total number of farms. The total value of animal products in 1899 was estimated at \$1,718,990,221, and the total value of all crops, including forest products, at \$3,020,128,531. The number of persons making agriculture their principal occupation was 10,438,121.

Cotton manufactures, E. STANWOOD (*Twelfth Census United States, Census Bul. 215, pp. 56*).—In 1900 cotton manufactures represented a capital of \$460,842,772, invested in 973 establishments and including the value of land, buildings, machinery, tools, and implements, exclusive of the capital stock of any of the corporations. The products of the industry represented a value of \$332,806,156. The figures for the manufacture of cotton small wares are not included in the above statement. Of this class there were 82 establishments with a capital of \$6,397,385, with products amounting in value to \$6,394,164. The total value of products in 1900 was 5.5 times as much as in 1850. The industry was then the leading manufacturing interest of the country and still holds that rank. Detailed statistics of the industry, including such items as imports and exports, the growth of the industry from decade to decade, its geographical distribution, the number of employees and their wages, together with other important data, are given in tables.

Historical development and present condition of agriculture in Roumania, C. JORMESCU (*Inaug. Diss., Univ. Bonn, 1901, pp. 151*).

Changes in agricultural management in Wurttemberg during the latter half of the nineteenth century, F. FRANCK (*Inaug. Diss., Univ. Jena, 1902, pp. 100, map 1*).—This work treats mainly of the changes which have taken place during the period in the acreage cultivated by the individual farmer, and in the conditions affecting the culture of crops and the raising of live stock.

Decreasing the culture of grain in favor of stock raising, E. VON RECHENBERG (*Inaug. Diss., Univ. Jena, 1902, pp. 79*).—This treatise compares the results of grain farming and stock raising and discusses under what conditions either the one or the other is profitable. A general review of agricultural conditions in Germany is also given.

Determination of net profits in agriculture, L. HUSCHKE (*Inaug. Diss., Univ. Jena, 1901, pp. 43*).—The economic phase of farming is considered in detail and calculations showing the net profits for small, medium, and large farms under conditions existing in middle Thuringia are presented. This dissertation forms part of a report on the conditions of German agriculture. An investigation of this subject was authorized by the Government.

Nature study (*Ontario Agr. Col. and Expt. Farm Bul. 124, pp. 79, figs. 96*).—This bulletin includes a series of articles written by members of the staff of the Ontario Agricultural College for the purpose of presenting "items of information and simple commonplace incidents regarding natural objects, in the hope of interesting . . . young people and inducing teachers to undertake such work in the Public and High Schools of the Province." The following subjects are discussed in a way which enables young readers to understand them: The origin, composition, and use of soil; the growth of plant roots; the growth of wheat; bread making; the yeast plant; butter making; bee keeping; apple growing; sugar production from the maple tree and the sugar beet; poultry raising; the cabbage butterfly; a number of common birds, and horse training.

NOTES.

ALABAMA COLLEGE AND STATION.—By a law recently enacted by the State legislature R. S. Mackintosh, horticulturist, has been made ex-officio State horticulturist. Fifteen hundred dollars per annum is appropriated to the college to enforce rules and regulations looking to the protection of fruit trees, vegetables, etc., against the San José scale, and insect pests in general. All nursery stock sold in Alabama by dealers within or without the State must carry the certificate of the State horticulturist. Jesse Jones, of Manhattan, Kans., succeeds R. W. Clark as assistant agriculturist.

ARIZONA STATION.—The Territorial legislature, during the session just ended, appropriated \$11,000 for the use of the station, to be expended particularly for the benefit of the date orchard and the station farm and for the dissemination of the results of the station work throughout the Territory by means of publications, farmers' institutes, and short courses of instruction. This appropriation places the station prospectively in a thoroughly satisfactory condition in all of its departments.

COLORADO COLLEGE AND STATION.—L. G. Carpenter, professor of civil and irrigation engineering in the college and director of the station, has been appointed State engineer.

FLORIDA STATION.—Geo. F. Mitchell has been appointed assistant in field experiments.

INDIANA STATION.—A newspaper report states that Arthur Goss, chemist of the New Mexico College and Station, has been elected director of the station, vice H. A. Huston, resigned.

MASSACHUSETTS COLLEGE AND STATION.—Ralph E. Smith, assistant botanist, has resigned to accept the position of plant pathologist at the California University and Station, and entered upon his new duties early in April. The State legislature has appropriated \$20,820 for the college, \$16,605 of which is for the completion of the new dining hall and central heating plant, \$1,115 for maintenance to cover the deficit in the income from the United States land grant, \$1,600 for fitting up an agricultural laboratory, \$500 for walks, \$500 annually for the maintenance of the heating and lighting plant, and the same amount for the dining hall. The bill providing a new feeding-stuffs law, previously mentioned, has been passed.

MISSOURI COLLEGE AND STATION.—The State legislature has just appropriated to the college and station \$62,600 for the following improvements and extensions: Veterinary hospital for contagious diseases, \$15,000; barn, \$10,000; improved live stock, \$5,000; plant house for work in plant physiology and pathology, \$7,500; additional equipment for dairy, horticulture, and live-stock buildings, \$9,000; experiment station, \$10,000. Provision has been made for an additional instructor in each of the following departments: Veterinary medicine, entomology, horticulture, botany, and extension work. The law concerning the manufacture and sale of commercial fertilizers was revised to relieve the station of the duty of analyzing samples of all the fertilizers before they were placed upon the market, and now requires the station to select samples in the open market and analyze the same. The analytical fee was abolished and the price of tags increased from 1 cent to 1½ cents each for packages of 100 lbs. or less, and 3 cents each for packages weighing more than 100 lbs.

MONTANA COLLEGE AND STATION.—At the session of the State legislature just closed an appropriation of \$5,000 a year was made for the maintenance of the station, \$5,500 for a central heating plant for the experiment station and agricultural buildings, \$3,000 for a seed house and granary, and \$13,000 for a cattle and dairy barn. These added facilities will strengthen both the college and station departments of agriculture and permit of developing lines of work for which there is very much need in the State, notably dairying.

NEW HAMPSHIRE COLLEGE AND STATION.—C. S. Murkland, president of the college, has resigned, to take effect May 1, 1903. Arthur L. Sullivan, assistant chemist of the station, has resigned to accept an appointment as analytical chemist in the Office of Internal Revenue of the United States Treasury Department.

CORNELL UNIVERSITY.—L. H. Bailey, professor of horticulture, has been appointed director of the college of agriculture and dean of the faculty of agriculture, to succeed I. P. Roberts upon his retirement.

NORTH DAKOTA STATION.—The legislature has made an appropriation of \$5,000 for a substation to be established at Edgeley.

OHIO STATION.—The station has established two additional test farms, one located at Germantown, in the tobacco district of southwestern Ohio, and to have the study of tobacco problems as part of its work; the other located at Carpenter, Meigs County, in the hill region of southeastern Ohio, and to be devoted to the special study of the problems peculiar to that region. The sandy land test farm in northwestern Ohio has been abandoned for the present.

OKLAHOMA COLLEGE AND STATION.—The governor has reappointed all the members of the board of regents, and their nominations have been confirmed by the council. The Territorial legislature has made some alterations in the funds for the maintenance of the college which will result in increasing the total revenue of the college to the extent of about 5 per cent. An appropriation of \$2,500 was made to the station to cover the cost of the manufacture and free distribution of blackleg vaccine.

OREGON STATION.—E. F. Pernot, bacteriologist, has obtained encouraging results in curing cheese in sealed cans with the aid of pure cultures. Experiments in controlling the flavor of cheese have been in progress at the station for two years past. By the new method, the fresh curd containing the pure cultures is placed in tin cans, pressed overnight in a cheese press, and the covers then soldered on. The ripening process is said to result in a cheese of superior and quite uniform flavor, and of a more friable and waxy texture than ordinary cheese, without rind or danger of mold.

PENNSYLVANIA COLLEGE.—In order to make the new library building more fully adequate to the needs of the college, Andrew Carnegie has increased his donation for that purpose from \$100,000 to \$150,000. The designs for the new library will be completed soon, and it is expected that the work of construction will be begun by May 1.

PORTO RICO STATION.—The insular legislature has appropriated \$5,700 for the station, \$2,000 of which is for tobacco experiments, \$1,000 for experiments with coffee, and \$2,700 for permanent improvements on the farm, such as fencing, underdraining, irrigation ditches, etc.

TEXAS COLLEGE AND STATION.—The following changes have been made in the governing board: K. K. Leggett, of Abilene; George T. Jester, of Corsicana; W. J. Clay, of Austin; A. Haidusheck, of Lagrange, and L. D. Amsley, of Hempstead, have been appointed, vice A. C. Oliver, Wm. Malone, A. P. Smyth; John W. Kokernot, and Jeff Johnson, retired. The new chemical-veterinary building recently completed is now occupied by the departments of chemistry and veterinary medicine. The large lecture room in this building has been used the past winter for holding a course of lectures by leading agriculturists and horticulturists, including a number from outside the State. E. P. Stiles, superintendent of the Troupe Substation, resigned

March 1. Instructor E. C. Green, of the horticultural department of the college, has been placed in charge of the station work temporarily.

WYOMING UNIVERSITY AND STATION.—The last legislature passed a pure-food bill, making the chemist of the station State chemist. The laboratories of the university were designated State laboratories to carry on this work, and an appropriation of \$1,000 per year was made to provide an assistant who will do the analytical work. It is expected that the station will be somewhat benefited in that the chemist will be aided in certain investigations of value to the station. The legislature also appropriated \$15,000 to build an armory and gymnasium.

U. S. DEPARTMENT OF AGRICULTURE.—F. H. Hitchcock, chief of the Division of Foreign Markets, has resigned to become chief clerk in the new Department of Commerce and Labor.

E. E. Ewell, assistant chief of the Bureau of Chemistry, has left the Department to have charge of the Atlanta office of the German Kali Works.

Filibert Roth, of the Bureau of Forestry, has been appointed professor of forestry in the University of Michigan.

Frank Bond, for two years past connected with the irrigation investigations of this Office, has resigned to accept the position of Chief of the Drafting Division of the General Land Office.

Harry Hayward, professor of animal industry and dairying in the New Hampshire Agricultural College, has been appointed assistant chief of the Dairy Division, and E. H. Webster, professor of dairying in the Kansas Agricultural College, has been appointed inspector and expert.

James L. Farmer, of Tennessee, has been appointed chief special agent for the college and station exhibit at St. Louis, and is temporarily located in the Office of Experiment Stations.

A. L. Quaintance, entomologist of the Maryland Agricultural College and Experiment Station, has resigned to accept a position in the Division of Entomology. He will have charge of the investigations on the cotton-boll weevil this season.

ASSIGNMENT OF SOIL SURVEY PARTIES, 1903.—The localities in which the soil survey will be carried on the present season by the Bureau of Soils is shown by the following table, the places named being the headquarters of the parties:

Soil survey, 1903.

Party in charge of—	April 1 to July 1.	July 1 to October 1.	October 1 to January 1.
Frank Bennett	Brookings, S. Dak.	Parsons, Kans.	Russell, Kans.
F. E. Bonsteel	Worcester County, Md.	Sussex County, Del.	Sussex County, Del.
J. A. Bonsteel	Long Island, N. Y.	Long Island, N. Y.	Long Island, N. Y.
R. T. A. Burke	Scott County, Ky.	Mason County, Ky.	Shelby County, Mo.
T. A. Caine	Fargo, N. Dak.	Fargo, N. Dak.	Lamar County, Tex.
G. N. Coffey	Sangamon County, Ill.	Johnson and Knox counties, Ill.	Winneshago and Ford counties, Ill.
E. O. Fippin	Connecticut Valley.	Connecticut Valley	Harpers Ferry, W. Va.
W. E. Hearn	Nacogdoches, Tex.	Grand Island, Nebr.	Norfolk, Nebr.
J. G. Holmes	San Luis Valley, Colo.	San Luis Valley, Colo.	Needles area, California.
C. A. Jensen	Salem, Oreg.	Baker City, Oreg.	Do.
J. E. Lapham	Norfolk, Va.	Asheville, N. C.	Asheville, N. C.
M. H. Lapham	Santa Clara, Cal.	Sacramento, Cal.	Sacramento, Cal.
A. W. Mangum	Pickens, S. C.	Saluda, S. C.	Orangeburg County, S. C.
H. W. Marcan	Storey County, Iowa	Cerro Gordo County, Iowa	Marshall County, Ala.
J. O. Martin	Clinton County, Pa.	Ashtabula County, Ohio.	Miller County, Ark.
L. Mesmer	Blackfoot, Idaho.	Laramie, Wyo.	Needles area, California.
T. D. Rice	Audubon Park, La.	Baton Rouge, La.	Southern Louisiana.
A. M. Sanchez	Utah County, Utah.	Milk River, Montana.	Needles area, California.
W. G. Smith	Yeroqua area, Wisconsin.	Davidson County, Tenn.	Lauderdale County, Ala.
H. J. Wilder	Lyon County, Minn.	Oakland County, Mich.	Pikeville, Tenn.

The headquarters for the tobacco work will be at Nacogdoches, Woodville, and Lufkin, Tex.; Marion, Perry County, Ala.; Hartsville, Darlington County, S. C.; Germantown, Ohio, and Hartford, Conn.

STATISTICS OF THE AGRICULTURAL COLLEGES AND EXPERIMENT STATIONS.—The statistics of these institutions for the past year have recently been compiled and are now in press as a bulletin of this Office. The summary shows that there are 66 colleges of agriculture and mechanic arts, 63 of which maintain courses of instruction in agriculture. The aggregate value of the permanent funds and equipment of the land-grant colleges and universities in 1902 is estimated to be \$67,544,888.25, of which the land-grant fund of 1862 furnishes \$11,369,031.50. The total number of acres of land granted to the States under the act of 1862 was 10,110,852, of which 1,010,845 acres, valued at \$4,315,546.06, remains unsold. The value of the farms, grounds, and buildings and equipment of these institutions is estimated at \$34,426,291.15.

The income of these institutions in 1902, exclusive of the experiment station funds, was \$9,166,272.82. Of this amount, \$682,960.65 was derived from interest on the land grant of 1862, \$72,098.63 from interest on other land grants, \$1,200,000 from the United States appropriation under act of 1890, and \$3,761,291.21 from State appropriations for current expenses, buildings, and other special purposes. The value of the additions to the permanent endowment and equipment of these institutions in 1902 is estimated at \$3,413,202.96.

The faculties of the colleges of agriculture and mechanic arts numbered 2,229 persons, and in other departments 1,050, making a grand total of 3,279 persons in the faculties of the land-grant institutions. The students in 1902 were as follows: (1) By classes—preparatory, 8,272; collegiate classes, 17,212; short or special courses, 5,114; postgraduate, 483; other departments, 16,334; total, 46,699. (2) By courses—agriculture, 6,299; mechanical engineering, 4,702; civil engineering, 2,146; electrical engineering, 1,814; mining engineering, 935; chemical engineering, 499; architecture, 336; household economy, 2,706; veterinary science, 977; dairying, 1,372; military tactics, 12,996. The graduates in 1902 numbered 4,443, and since the organization of these institutions, 50,026. The average age of graduates in 1902 was 21 years and 11 months.

There are now 60 agricultural experiment stations, excluding the substations, and of these 55 receive appropriations provided for by act of Congress. In Connecticut, New Jersey, New York, Hawaii, Missouri, Alabama, and Louisiana separate stations are maintained wholly or in part by State funds.

The total income of the stations during 1902 was \$1,328,847.37, of which \$720,000 was received from the National Government, the remainder, \$608,847.37, coming from the following sources: State governments, \$369,771.12; individuals and communities, \$2,301.38; fees for analyses, \$80,942.36; sales of farm products, \$105,644.60; miscellaneous, \$50,187.91. In addition to this the Office of Experiment Stations had an appropriation of \$139,000 for the past fiscal year, including \$12,000 for the Alaska experiment stations, \$12,000 for the Hawaiian investigations, \$12,000 for the Porto Rico investigations, \$20,000 for nutrition investigations, and \$50,000 for irrigation investigations. The value of additions to the equipment of the stations in 1902 is estimated at \$262,829.62.

The stations employ 710 persons in the work of administration and inquiry, not including the regular or temporary laborers. Of these 56 are directors or special agents in charge of stations, 151 chemists, 54 agriculturists, 7 agronomists, 25 animal husbandmen, 73 horticulturists, 50 botanists, 20 mycologists and bacteriologists, 56 entomologists and zoologists, 8 biologists, 34 dairymen, 27 veterinarians, 12 meteorologists, 5 physicists, 4 geologists, and 9 irrigation engineers. Three hundred and sixty-four station officers do more or less teaching in the colleges with which the stations are connected.

The activity and success of the stations in bringing the results of their work before the public continue unabated. During the year they published 373 annual reports and bulletins, which are many more than are required by the Hatch Act. These were supplied to over half a million addresses on the regular mailing lists. A larger

number of stations than formerly supplemented their regular publications with more or less frequent issues of press bulletins, and most of the stations report a large and constantly increasing correspondence with farmers on a wide variety of topics.

ONTARIO AGRICULTURAL COLLEGE.—A short course in stock and grain judging for farmers' institute workers was held at the college this year for the first time. The course opened March 17, and continued for two weeks. It included judging exercises with horses, beef and dairy cattle, sheep, swine, and grain, including the identification of weed seeds found in grass seed and clover seed.

THE SCHOOL OF PRACTICAL AGRICULTURE AND HORTICULTURE AT POUGHKEEPSIE.—This school, recently removed from Briarcliff Manor, is to be closed on account of failure to secure the necessary funds for buildings and general equipment. The furnishings of the two leased buildings which it occupied and the stock and implements on the farm will be sold.

DOYLESTOWN FARM SCHOOL.—The trustees have decided to purchase a tract of land as an addition to the farm, at a cost of \$5,000. The Pennsylvania legislature has appropriated \$15,000 toward the maintenance of the school.

WINONA AGRICULTURAL AND TECHNICAL INSTITUTE.—This is a secondary school for boys, opened last September at Winona Lake, Ind., and is located on the grounds of the Winona Assembly and Summer School. The course of study embraces six years of work, two in the preparatory department and four in the academic. The subjects having an agricultural bearing are soils and crops, farm buildings, breeds of live stock, history of agriculture, dairying, agricultural engineering, feeds and feeding, entomology, economic botany, horticulture, agricultural physics, and chemistry. In addition to these subjects, instruction is given in literature, mathematics, history, science, manual training, language, the Bible, vocal music, and physical culture. The enrollment this year is nearly 90, and includes boys from 11 different States and 3 foreign countries. A memorial to be known as the James A. Mount Building will be ready for occupancy in the fall.

NEW PERIODICALS.—The Pasteur Institute of Paris has recently issued a new publication entitled *Bulletin de l'Institut Pasteur*. The first number bears the date February 28, 1903, and the publication is to be issued bimonthly. The purpose of this Bulletin is to furnish to persons who are interested in micro-biology in its broadest sense reviews and abstracts of current literature in this field. The material contained in the *Bulletin* is divided into 2 classes, viz, reviews and abstracts. The reviews deal in a critical manner with subjects of general interest, and are intended for the use of persons who are not experts in micro-biology or actually occupied in investigations in this field. The abstracts will be made to cover all publications on bacteriology, medicine, general biology, physiology, and biological chemistry, in so far as these may be connected with the subject of micro-biology. The abstracts are classified into 8 groups according to the subjects involved, as follows: General works, text-books, micro-biology, technique, instruments, cultures, staining; morphology and classification of microbes; works on general biology as related to micro-biology; chemical actions exercised by microbes, agricultural and industrial micro-biology; pathogenic effects of microbes, etiology of diseases, experimental infections, reactions of the organism; microbic and cellular toxins, cytotoxins, diastases; phagocytoses, immunity, vaccination, serotherapy; and hygiene, prophylaxis, disinfection.

Naturwissenschaftliche Zeitschrift für Land- und Forstwirtschaft (Natural Science Journal for Agriculture and Forestry) is the title of a new periodical which appeared early in the year. It is a monthly journal, edited by Prof. Carl Freiherr von Tübeuf and Dr. Lorenz Hiltner, both of Munich, who have associated with themselves as collaborators a long list of specialists prominent in various branches of agriculture and forestry. The scope of the new journal will embrace the anatomy, physiology,

and biology of agricultural plants and forest growths, the chemistry and physics of the soil, meteorology, and injurious diseases and insects. Both original articles and abstracts will be published, together with notes and personal items.

The Royal Bavarian Agricultural-Botanical Institute, which was opened at Munich last October, with Dr. L. Hiltner as director, has begun the publication of an organ known as *Praktische Blätter für Pflanzenbau und Pflanzenschutz*. Judging from the announcement and the first number, it is to be a sort of popular bulletin, issued monthly and confined to brief accounts of matters of direct interest to the practical farmer. As the popular organ of a German scientific institution and edited by the director, it is of interest as marking a rather unusual departure.

MISCELLANEOUS.—A note in *Science* states that the Government of Nicaragua will send 15 students annually to colleges of agriculture in the Southern States.

An experiment farm of 50 acres near Comanche, Tex., is reported to have been established by the "Eisco System," with the object of assisting the farmers of the region in raising hogs, interest in which has been increased by the establishment of a packing house at Fort Worth.

As previously announced (p. 532) the Carnegie Institution has made a grant of \$8,000 for the establishment and maintenance of a desert botanical laboratory. Acting on the recommendation of the committee appointed to look after the location and management of the laboratory, F. V. Coville and D. T. MacDougal, the regents have decided to locate the laboratory on a tract of about 50 acres of land near Tucson, Ariz. A laboratory building will be erected there at an early date.

The Sharon Biological Observatory, a summer school for teachers at Sharon, Mass., will, according to *Science*, experiment in forestry on a tract of 300 acres of woodland which it purposes making into a model forest. Applications have been made to the Bureau of Forestry for a working plan.

G. M. Odium, a graduate of the Michigan Agricultural College in 1900, now farm manager of the Methodist Episcopal Estate, Umtali, Rhodesia, is in this country to study the farm machinery in use on large ranches in our Western States, with a view of purchasing and exporting suitable steam-power plows and other implements for use on the estate in his charge. This estate contains about 13,000 acres, and, while not officially connected with the agricultural department of Rhodesia, a small area is being used by Mr. Odium for demonstration experiments with cereals, legumes, forest trees, and in irrigation, under the auspices of that department.

The department of agriculture of Rhodesia, located at Salisbury, has until this year been a division of the surveyor-general's department, but is now an independent organization consisting of the secretary of agriculture, E. Ross Townsend, an agriculturist, a register of brands, a staff of clerks, and the veterinary service, which includes a chief veterinary surgeon and five assistant surgeons. The department cooperates with farmers in experiments with cotton and tobacco, maintains a free veterinary service, and publishes bulletins for distribution among the farmers. Mr. Odium will spend considerable time studying the work of the U. S. Department of Agriculture, more especially with reference to the tobacco investigations, for the purpose of making a comprehensive report to the department of agriculture of Rhodesia.

EXPERIMENT STATION RECORD.

VOL. XIV.

MAY, 1903.

No. 9.

Perhaps no line of research with farm animals promises more important returns to station workers than digestion experiments and other studies with horses. This is brought out by a recent compilation of investigations on horse feeding, by Dr. C. F. Langworthy, of this Office, which summarizes late work on the subject, and especially such as has been done by the American stations. It is evident from this that while there is an abundance of data regarding the composition of the comparatively small number of feeding stuffs ordinarily given to horses, the data regarding the digestibility of the different materials is quite limited, both in respect to the number of feeding stuffs studied and the number of experiments with any given feed. For instance, record was found of only about thirty-six tests with oats, thirty with meadow hay, and twelve with alfalfa, feeding stuffs which have apparently been most often selected for studies of digestibility. These numbers do not include numerous experiments in which these materials form part of a mixed ration and no attempt was made to determine the digestibility of single materials.

It appears that the work of the stations in the United States along these lines is limited to a single series which was carried on at the Maryland Station. Further experiments are much needed with such common feeding stuffs as green grasses and clover, timothy, clover, and other hays, corn silage, wheat, barley, wheat bran, wheat shorts, dried brewers' grains, gluten meal, linseed meal, etc. The digestibility of some of these has apparently never been studied with horses, while in other cases more figures are needed in order that satisfactory average values may be available.

Additional feeding experiments under different conditions could also be made with profit to supply accurate data regarding the comparative economy of various feeding stuffs and rations, their wholesomeness and effectiveness when fed for long periods; and related topics. It is a common practice to feed horses an abundant ration before they are sold in order that they may reach market in good condition. So far as can be learned practically no studies have been made of the value

of different rations for this purpose, the length of time the feeding should be continued, and the comparative cost of the gains made.

In the compilation referred to data are summarized showing the amounts fed to their horses by fire companies, express companies, packing houses, and others employing large numbers of animals, as well as the rations fed to farm horses at the experiment stations. On an average the ration of the American draft horses at light labor was found to supply, per thousand pounds live weight, approximately one pound of digestible protein and fifteen thousand calories of energy. Similar values for horses at moderate work are one and one-half pounds of digestible protein and twenty-three thousand calories. These values are considerably lower than those called for by the Wolff-Lehmann feeding standards. It is interesting to note that, basing his deduction on data of an entirely different character, Zuntz has pointed out that the Wolff standards are too high. Other investigators have reached the same conclusion. The subject is certainly worth the attention of American investigators, as the importance of devising suitable feeding standards for horses can hardly be overestimated.

So far both American and foreign experiments with horses, generally speaking, have been limited to draft animals and army horses. The food requirements of hunters, driving and carriage horses, and other fancy classes is practically an unworked field so far as experimental investigations are concerned.

The Library of Congress has commenced the printing of a series of cards which will be helpful to those in charge of agricultural libraries and to the users of such libraries in general. This series of cards is devoted to the accessions which are being constantly made to the Library of this Department. These are uniform in size with the catalogue cards now so generally used by libraries, and contain the name of the author and title of the book, and a quite full description, the contents frequently being noted. They are available for purchase by libraries and individuals, for incorporation in card catalogues, or for record purposes. All or only a portion of the cards of this series may be ordered, and as many copies of each title as are desired, to suit the purpose for which they are used.

Each card bears the imprint of the Department Library, and serial numbers are given which correspond with the numbers in the Accessions to the Department Library, issued quarterly. This furnishes a convenient means of selecting and ordering the cards, which are distributed by the Library of Congress. The charge is two cents each for single copies, and one-half cent each for additional copies or duplicates. Although every card need not be purchased unless desired, lists should be made up in the serial order of the cards, for convenience in filling the order, and where this is not done a slight additional charge is made.

It will thus be seen that the convenience and purpose of the user has been considered in allowing a selection of cards along any given subject or class of publications, and in providing duplicates at slight cost for cross-reference or other purposes. Up to the present time about eight hundred titles have been printed.

The value of these cards and the use which may be made of them will be quite evident. The Department of Agriculture is expending through its Library about seven thousand dollars a year in the purchase of books. These are for the most part on subjects relating quite directly to agriculture and agricultural science, and include all the new books of value which come to the notice of the Librarian and the large corps of Department workers in various lines, as well as many old and rare works. The Department Library is fast becoming an unusually complete repository of historical and new literature on agriculture and the sciences relating to it, and its lists of accessions have a special value to persons interested in that field.

The printing of these cards will be a convenience to libraries, as they may be incorporated in any card catalogue and thus save the labor of cataloguing a book which the library has, or show where it may be found. They contain much more information than the ordinary library card, and are less expensive. In time they will naturally form quite extensive bibliographies on a variety of subjects, and thus enhance the value of the small library for reference purposes. For the agricultural colleges and experiment stations they have a special value, and will be an increasingly useful contribution.

The Department Library is now engaged in preparing a card catalogue of the contents of scientific periodicals, and will begin printing this soon. A selected list of the more important journals has been made, and these will be catalogued in order, beginning in each case with the first volume of the journal. Cards will be made not only for the title of each article, but for each important subdivision of the article, making the catalogue quite detailed and enabling intelligent classification of the cards.

This undertaking is in line with the suggestion of the Committee on Indexing Agricultural Literature, which has been working in this direction for several years past. It will be of the greatest assistance in looking up literature upon any subject, and will be available to all college and station men, as sets will be distributed gratis to the college and station libraries. As the sets of periodicals included in the catalogue are all on the shelves of the Department Library, and as these books are now loaned out to college and station men under certain restrictions, this catalogue of periodical literature will help to relieve the difficulties of workers at institutions where library facilities are meagre.

The National Institute of Agriculture at Paris has recently issued an illustrated volume of nearly six hundred pages giving a historical account of this institute, especially during the period from 1876 to 1901, and a description of its present organization and work.^a The institute was established at Versailles in 1848, but was suppressed in 1852 and was reestablished in Paris August 9, 1876. The founder of the institution was Eugène Tisserand. The volume contains lists of the various men who have held professorial chairs in the institution, and also its present organization, together with bibliographical lists of the works published by the various professors. M. Tisserand was director from 1876 to 1879, M. Risler from 1879 to 1900, and the present incumbent is Paul Regnard.

The instruction given at the institute is both theoretical and practical, and is intended to turn out expert agriculturists, with the necessary practical and scientific knowledge for managing farms and estates, becoming administrative officers in the agricultural work of the government, instructors in special lines, directors and investigators in experiment stations, agricultural engineers, and similar callings where expert knowledge is required.

Although primarily an institution for instruction, a number of special experiment stations have been established in connection with the institute, as departments of it or under its general supervision. Among these are the Station for Seed Testing, established in 1884, now under the direction of E. Schribaux; the Station for Testing Agricultural Implements, established in 1887, of which M. Ringelmann is director; the Laboratory of Fermentations, established in 1888, under E. Duclaux; the Station for Vegetable Pathology, established in 1888, under the direction of M. Delacroix; the Entomological Station, established in 1894, now in charge of M. Brocchi; the Viticultural and Enological Laboratory, under the direction of M. Viala; and the Experiment Station for Agricultural Hydraulics, with M. Hérisson at its head. These various laboratories receive third-year students who serve to some extent as assistants in the laboratory work.

This memoir of the National Institute of Agriculture, which is the capstone of agricultural education in France and one of the foremost institutions of its kind in the world, contains much which is of interest and of permanent value to the student of agricultural education and investigation.

^aL'Institut National Agronomique de 1876 à 1901.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

On the colorimetric determination of small quantities of phosphoric acid and silica, F. P. VEITCH (*Jour. Amer. Chem. Soc.*, 25 (1903), No. 2, pp. 169-184).—This article reports a study of the conditions affecting the accuracy of the Lepiere ^a colorimetric method for phosphoric acid as worked out in detail by Woodman and Cayvan (*E. S. R.*, 13, p. 319), viz, the influence of turbidity, organic matter, ammonium and iron salts, dissolved silica, etc., and means of overcoming the errors thus introduced. The method proposed by the author for the determination of phosphoric acid and silica in the same soil solution is as follows:

"The water or extract is tested for iron by adding potassium ferrocyanid to the acidified solution. The absence of interfering amounts of iron having been shown, a measured volume of the water or soil extract is freed from suspended matter by filtration or by passing through a Chamberland filter (reject the first 100 cc. that passes) or by evaporating to dryness and filtration, or in some cases where the water is but slightly turbid the turbidity or color is corrected for by determining its amount in terms of the standard, the reading thus obtained being afterwards subtracted from the final readings. Add to the clear extract 5 cc. of nitric acid (sp. gr. 1.07) and 4 cc. of molybdate solution. Place in the camera, allow 10 to 30 minutes for development of color, and compare with a standard phosphate solution, which may conveniently contain 10 parts per million of phosphorus pentoxid and be contained in a sliding tube connected by rubber tubing with a side neck tube graduated in cubic centimeters within the camera. (The color of the standard is not affected by the rubber tube during one working day, but the standard should be made fresh each day.) The readings thus obtained (several should be made and the average taken) minus the reading for turbidity, when calculated to a volume of 100 cc., equals $P_2O_5 + SiO_2$ in parts per million of solution.

"Another measured portion of the water or extract is evaporated to dryness twice with a filtration between the evaporations in a porcelain or platinum dish with 3 cc. nitric acid (sp. gr. 1.07) plus a little magnesium nitrate,^a heated 2 hours in a water oven, 5 cc. nitric acid (sp. gr. 1.07) added, filtered, washed to about 45 cc., placed in a camera, and compared. If colored, the reading is noted and is finally subtracted from the total reading. Add 4 cc. of ammonium molybdate and thoroughly mix. Place in the camera and compare after 2 to 5 minutes. The corrected reading calculated to volume of 100 cc. is P_2O_5 in parts per million of solution. This reading subtracted from the $SiO_2 + P_2O_5$ reading and the difference multiplied by 0.55 gives the silica.

"Where the original solution is too much colored with organic matter to be accurately corrected for by reading the color thus produced against the standard phosphate solution, it is necessary to evaporate with about 0.1 gm. magnesium nitrate ^b and burn off the organic matter, take up with water + 3 nitric acid, evaporate to dry-

^a *Bul. Soc. Chim. Paris*, 15 (1896), p. 1213.

^b "In solutions containing sufficient base to form normal phosphates with all the phosphoric acid, the addition of magnesium nitrate appears to be unnecessary."

ness, and heat 2 hours in the water oven. Add 5 cc. nitric acid and proceed as above. Readings = P_2O_5 . In this case silica is not determined."^a

Various precautions to be observed are noted and results of tests of the method are reported which show that "there is a maximum error of ± 2 scale divisions (each scale division = 1 cc.) in the reading. When the soil solution is made by treating 1 part of soil with 5 parts of water and 50 cc. are taken for the determination, the error on the dry soil is ± 2 parts per million cc.; when 100 cc. are taken for the determination, the error is ± 1 part per million, so that the working errors may only be neglected when at least 200 cc. of solution are taken for the determination."

Determination of citric-soluble phosphoric acid in Thomas slag by the molybdate method, H. NEUBAUER (*Ztschr. Angew. Chem.*, 15 (1902), No. 44, pp. 1133-1135; *abs. in Analyst*, 28 (1903), No. 323, p. 50).—The author recommends a molybdic solution containing in 2 liters 150 gm. of ammonium molybdate and 1 liter of nitric acid (1.2 sp. gr.), since it is claimed that such a solution does not precipitate silicic acid from the citric-acid solution of the slag. Moreover, the precipitation with this solution is complete after 15 minutes' heating at 80° C. and 30 minutes' standing, and the precipitate is dense and easily washed.

Determination of phosphoric acid in Thomas slag, O. KELLNER and O. BÖTTCHER (*Chem. Ztg.*, 26 (1902), No. 37, p. 1151; *abs. in Analyst*, 28 (1903), No. 323, p. 50).—If a precipitate which is not entirely soluble in hydrochloric acid is formed by adding to the Wagner extract of the slag an equal volume of a reagent made by dissolving 1,100 gm. of citric acid in water, adding 4,000 gm. of 24 per cent ammonia and diluting to 10 liters, boiling for 1 minute, and allowing to stand 5 to 10 minutes, the silica of the slag should be removed, before the phosphoric acid is precipitated with magnesia mixture, by the Böttcher method (*E. S. R.*, 9, p. 520).

Chemical analysis of soils, R. CORRADI (*Bol. Chim. Farm.*, 41 (1902), pp. 419-424, 675-678; *abs. in Chem. Centbl.*, 1902, II, No. 21, p. 1340).—This article discusses methods of sampling and chemical and physical analysis. The calcium carbonate content of the soils is calculated from the loss of weight on treatment of the soil with hydrochloric acid in a special apparatus which is described. Total phosphoric acid is determined in nitric acid solution of the soil by multiplying the weight of ammonium phosphomolybdate precipitate by 0.0355. In certain cases the phosphoric acid, magnesia, potash, and soda combined with humus are determined. The direct precipitation method of Corenwinder and Contamine is used for potash.

A chemical method for determining the quality of limestones, A. M. PETER (*Jour. Amer. Chem. Soc.*, 25 (1903), No. 2, pp. 143-150).—Proceeding on the theory that the rapidity of disintegration of limestones depends upon the proportion of oxidizable material—ferrous phosphate, organic matter, etc.—the author proposes to measure the quality of limestones for building and road-making purposes by dissolving "the limestone in dilute sulphuric acid in the presence of a known amount of potassium permanganate and determining how much permanganate has been reduced during that process, after which the solution is to be used for the determination of phosphoric acid by a rapid volumetric method, and the insoluble residue for the determination of the insoluble matter and clay." The details of the method are explained, and the results of its use in the examination of a number of samples are reported. "The conclusion would seem justified that the limestone which consumes much more than 0.3 per cent of oxygen and at the same time contains as much as 1 per cent of phosphoric acid, more especially if it contains also several per cent of clay, will disintegrate rapidly upon exposure to air and moisture and will be undesirable for road building or other exposed construction."

The determination of atmospheric carbon dioxide by the Walker method, A. G. WOODMAN (*Jour. Amer. Chem. Soc.*, 25 (1903), No. 2, pp. 150-161, figs. 2).—

^a "Or the organic matter may be destroyed by treating with aqua regia in the presence of sufficient base to prevent loss of phosphoric acid."

This method^a is briefly outlined as follows: "To a definite volume of air, usually 1 to 2 liters, is added a measured amount of standard barium hydroxid, care being taken to avoid contact of the solution with the air. After the absorption of the carbon dioxid the solution is filtered under reduced pressure through asbestos and the clear barium hydroxid received into a known excess of standard hydrochloric acid. The absorption vessel is rinsed out with water free from carbon dioxid. The excess of acid is then determined by titration with barium hydroxid." Reagents and apparatus required for carrying out the method are described in detail and numerous tests of its accuracy are reported. "The results obtained confirm Walker's statement that the method is accurate under ordinary circumstances to 0.1 part in 10,000. . . . With a little practice the method was found to be rapid and easy of execution and preferable to the Pettenkofer method."

The oxidation of organic nitrogen compounds and the estimation of the carbon and nitrogen therein by the moist process, E. VAN AKEN (*Proc. Soc. Sci., Koninkl. Akad. Wetensch. Amsterdam*, 4 (1901-2), pp. 91-95).—Tests are reported which show that Fritsch's method^b gives too low results in case of certain amids and urea derivatives. This appears to be due largely to the relative proximity of the nitrogen atoms in the compounds. The use of an oxidizing agent like chromic acid in the Kjeldahl process does not obviate the difficulty.

Report on the determination of constants for use in the preparation of hydrographic tables, M. KNUDSEN ET AL. (*K. Danske Vidensk. Selsk. Skr.*, 6. ser., 12 (1902), No. 1, pp. 15, figs. 18).—This includes papers on the collection and preparation of water samples, the determination of specific gravity, determination of chlorin and salt, and expansion of sea water.

On the impurities in compressed oxygen and their rôle in combustion in the bomb calorimeter, M. BERTHELOT (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 30, pp. 821-824).—The author finds that in the amount of compressed oxygen used for carrying out a combustion with the bomb calorimeter no carbon dioxid or at least only a negligible quantity is contained. However, the oxygen was found to contain 0.0005 gm. hydrogen, which would by oxidation produce a small quantity of heat. He believes, therefore, that the quantity of hydrogen mixed with the oxygen should be determined.

The nature, determination, and distribution of the pentosans in the Sea Island cotton, F. S. SHIVER (*South Carolina Sta. Bul.* 78, pp. 38).—The literature of pentosans and their determination is reviewed at considerable length, the phenylhydrazin and phloroglucin methods of analysis as used by the author are given, and determinations by both methods of the pentosan content of Sea Island cotton and its parts are reported. The finest and coarsest varieties of cotton of the crops of 1896 and 1898 were used. The following table summarizes the main part of the data:

Pentosans in Sea Island cotton.

Parts.	Percentages of parts.		Pentosans by phenylhydrazin method.				Pentosans by phloroglucin method.			
			Crop 1896.		Crop 1898.		Crop 1896.		Crop 1898.

^aJour. Chem. Soc. [London], 77 (1900), p. 1110.

^bLiebigs Ann. Chem., 294 (1897), p. 79.

The average pentosan content of Sea Island cotton-seed meal of the crops of 1897 and 1898 determined by both methods was 12.92 per cent. "From this work we see that the pentosans are widely distributed in the Sea Island cotton plant and all its parts and products. The average amount present varies from 1.53 per cent in the lint up to 21.88 per cent in the hulls. From their wide distribution it is highly important that the pentosans should always be determined in all proximate analyses." The work of others is summarized to show that these bodies apparently have a slightly less food value and lower digestibility than the other well-known and commonly occurring constituents of the nitrogen-free extract. "In conclusion, it appears from the close relation existing between the pentosan and crude-fiber content that the true function of the pentosans in the plant economy is the formation of the cell membrane, as Stoklasa [E. S. R., 11, p. 121] has already observed."

Solutions for testing cream and milk, J. B. WEEMS and C. E. GRAY (*Iowa Sta. Bul.* 67, pp. 266-272).—Standard solutions for testing milk and cream, prepared from commercial alkaline tablets, according to the directions accompanying them, were found to have strengths from 12.4 to 14.8 per cent greater than a tenth-normal solution. Exposure of the tablets for about 6 months reduced these figures nearly 10 per cent. Solutions repeatedly frozen and completely thawed did not change in strength. The use of the liquid portion of a partly frozen solution was found to give inaccurate results. Exposure of a standard solution in an open vessel reduced its strength one-third in 5 days. Limewater prepared from either pure or common lime at 66° F. had a strength equal to 0.45 per cent of a tenth-normal solution. Suggestions are given as to the use of standard solutions, the preparation of tenth-normal from normal solutions, and the preparation of a solution of phenolphthalein for use as an indicator.

On the determination of moisture in honey, F. T. SHUTT and A. T. CHARRON (*Trans. Roy. Soc. Canada*, 2. ser., 8 (1902-3), III, pp. 35-46, pl. 1).—Several methods of determining moisture in honey were compared, with conclusions substantially as follows: "In drying a solution of honey in glass tubes on asbestos, a temperature of 98° C. at atmospheric pressure induces a considerable and continuous dehydration of the levulose, resulting in an apparent loss of moisture far exceeding the real amount present. Drying in glass tubes on asbestos at atmospheric pressure between 70 and 75° also occasions a decomposition of the levulose of the honey. . . . Drying in platinum dishes on sand in a partial vacuum (8 in.) at a temperature of 60 to 70° for 24 to 48 hours, yields results in close accord with those calculated from the specific gravity determinations. A more prolonged drying is undesirable, as such appears to induce a slight decomposition of the levulose. Drying on asbestos yields much higher results than drying on sand. This, apparently, is as true at 60° as at 70°, and indicates a peculiar property or quality of the asbestos in inducing decomposition of the levulose. There were no differences of note between the results from drying in round and flat bottom platinum dishes." Similar determinations were made on solutions of levulose and dextrose, the results agreeing very well on the whole with those obtained on solutions of honey.

Some notes concerning Halphen's test for cotton-seed oil, E. FULMER (*Jour. Amer. Chem. Soc.*, 24 (1902), No. 12, pp. 1148-1155).—The reaction was found to be greatly diminished in intensity by heating the oil to 220 to 240° C. and negative in oil heated to 260 to 270° C. Lard from pigs fed cotton-seed meal showed an intensity of coloration by this test equivalent to several per cent of cotton-seed oil.

Iodin absorption of oils and fats, L. M. TOLMAN and L. S. MUNSON (*Jour. Amer. Chem. Soc.*, 25 (1903), No. 3, pp. 244-251).—Previously noted (E. S. R., 14, p. 523).

Does cholesterol occur in maize oil? A. H. GILL and C. G. TUFTS (*Jour. Amer. Chem. Soc.*, 25 (1903), No. 3, pp. 251-254).—Previously noted (E. S. R., 14, p. 523).

Determination of stearic acid, H. KREIS and A. HAFNER (*Ztschr. Untersuch. Nahr. u. Genussmittel*, 6 (1903), No. 1, pp. 22-27).

Examination and composition of lemon juice, K. FARNSTEINER (*Ztschr. Untersuch. Nahr. u. Genussmittel*, 6 (1903), No. 1, pp. 1-22).—Methods of analysis are given and discussed and analytical data reported.

The identification and composition of malt liquors, C. L. PARSONS (*Jour. Amer. Chem. Soc.*, 24 (1902), No. 12, pp. 1170-1178).—The results of analyses of 76 samples of American malt liquors as compared with analyses published some years ago by the Division of Chemistry of this Department indicated a more general use of glucose in their manufacture. About 50 per cent of the samples contained salicylic acid. The author discusses the analytical data reported as regards the probable use of malt in the production of the liquors sampled. Methods of analysis are given.

The standardization of sulphuric acid, F. S. SHIVER (*South Carolina Sta. Bul.* 77, pp. 7).—Comparative tests of the barium chlorid and ammonium sulphate methods for the standardization of sulphuric acid showed very close agreement between the two methods. The ammonium sulphate method is considered fully as accurate and far more simple and rapid than the barium chlorid method. The author also compared with the barium chlorid method, which was taken as a standard of accuracy in the work, the two indirect methods proposed by S. P. L. Sorensen, which are based upon the use of sodium oxalate and sodium bicarbonate, respectively. Both these methods gave lower results.

Analysis of tanning materials, W. H. TEAS (*Jour. Soc. Chem. Ind.*, 22 (1903), No. 3, pp. 128-130).—This was presented at the last convention of the Association of Official Agricultural Chemists (E. S. R., 14, p. 113).

Liquid baths for melting point determinations, H. SCUDDER (*Jour. Amer. Chem. Soc.*, 25 (1903), No. 2, pp. 161-163).—For temperatures below 325° C., a mixture prepared by boiling together for 5 minutes 7 parts by weight of sulphuric acid (sp. gr. 1.84) and 3 parts by weight of potassium sulphate is considered suitable, and for temperatures from 360 to 600° a fused zinc chlorid bath has been found the most satisfactory. The boiling point of the sulphuric acid and potassium sulphate mixture may be increased to 365° by taking 6 parts by weight of the acid and 4 parts of the sulphate.

The prevention of bumping, H. SCUDDER (*Jour. Amer. Chem. Soc.*, 25 (1903), No. 2, pp. 163-165).—Directions are given for the use of a single glass capillary tube for this purpose, the method being considered simple and effective for ordinary laboratory work.

A water jacket of constant ordinary temperature, J. C. SCHALKWIJK (*Proc. Soc. Sci., Koninkl. Akad. Wetensch. Amsterdam*, 4 (1901-2), pp. 29-35, pl. 1).

A new form of Kjeldahl apparatus (*Apoth. Ztg.*, 17 (1902), p. 817; *abs. in Chem. Centbl.*, 1903, I, No. 3, p. 194).

Report of the senior analyst for the year 1901, C. F. JURITZ (*Rpt. Senior Analyst, Cape Good Hope*, 1901, pp. 61, map 1, dgm. 1).—This is a report upon the 1,389 miscellaneous samples analyzed during the year. Of this number 634 samples were food products, of which 114 were found adulterated. The number of samples of soils analyzed was 63 and fertilizers 40. Numerous samples of sheep dips, disinfectants, and minerals were also examined.

Chemical division, B. C. ASTON (*New Zealand Dept. Agr. Rpt. 1902*, pp. 109-126).—Analyses of 8 samples of butter, 12 of milk and cream, 55 of potable waters, 31 of fertilizing materials, 25 of soils, and numerous miscellaneous samples are reported, together with the results of examination of Babcock glassware. A preliminary note is made on a chemical study of the karaka nut (*Corynocarpus laevigata*). The kernel is known to be poisonous in its raw state, but suitably prepared, is used as a food. Prussic acid was obtained from the aqueous extract by distillation. A bitter crystalline substance, to which the name "karakin" is given, was obtained, the method of preparation and the properties of the compound being described.

Handbook of inorganic chemistry, O. DAMMER (*Handbuch der anorganischen Chemie*. Stuttgart: Ferdinand Enke, 1903, vol. 4, pp. XXIV+1023).—Abstracts of the literature of inorganic chemistry from 1892 to 1902.

Results of agricultural chemistry, A. MAYER (*Resultate der Agrikulturchemie*. Heidelberg: Carl Winter, 1903, pp. VIII+269, figs. 28).—This is a condensed summary of what the author considers the most important practical results of investigations in agricultural chemistry. It is based on the fifth revised edition of the author's larger treatise on agricultural chemistry, but is less technical in style and therefore better suited to the purposes of the general reader.

Agricultural chemistry, I. GIGLIOLI (*Chimica agraria, campestre, e silvana*. Naples: Marghieri, 1902, pp. XVIII+877, figs. 31; rev. in *Nature*, 67 (1902), No. 1730, p. 169).

Annual report of the progress in animal chemistry, R. ANDREASCH and K. SPIRO (*Jahresber. Thier. Chem.*, 31 (1901), pp. XXVII+1054).—This contains abstracts of the literature of animal chemistry for 1901, with subject and author indexes. The volume is prefaced with a brief biographical sketch of the late M. Nencki, one of the previous editors of this publication, and a list of the publications of Nencki and his pupils.

BOTANY.

Studies in the vegetation of the State. II. The relation of the water content of the soil to certain plants, principally Mesophytes, G. G. HEDGCOCK (*Univ. Nebraska, Bot. Survey Nebraska*, 1902, VI, pp. 79; abs. in *Bot. Centbl.*, 90 (1902), No. 25, pp. 695, 696).—The results of experimental studies of the conditions influencing the growth of plants in different soils, the water content of the soils, and the relative amount of water in the plants are given, together with statements as to the influence of drought on plants. The amount of "physical" water in soils was found to vary directly with the water-retaining capacity of the soils. The chief known factors influencing the water content are gravity, capillarity, surface tension, and evaporation. The amount of physiological water in soils, i. e., that available for the use of plants, varies directly with the total amount of water held in the soil, and inversely with the amount of hygroscopic water. The adaptability and vigor of the plant varies according to its power to draw water from the soil. The amount of water in the soil which is not available for the use of the plant is dependent directly upon the ability of the plant to withdraw water from the soil. The soil composition and texture directly affect the ability of the plant to withdraw the water.

The percentage of water in the tissues of the plant is usually greatest in seedlings and decreases gradually as the plants grow older. Plants containing the highest percentage of water are not necessarily the healthiest, as frequently the most vigorous growing plants were found to contain a considerably lower percentage of water than less thrifty ones. Shade plants and plants grown under humid conditions have a relatively high water content, due probably to the poor development of the fibrovascular system.

Mesophytic plants apparently lose water when first wilting in about the same ratio by weight as the soils. This probably indicates that the plant gets little or no water from the soil after it begins to wilt excessively and that the root system is already beginning to die at the extremities. Xerophytic plants lose weight very slowly when subjected to drought and some retain most of the water in their tissues even when the substratum is practically air dry. The percentage of water in dying plants varies not only with the species but also with the individuals. Seedlings die with a greater percentage of water in their tissues than older plants, and mature plants when dying contain the minimum percentage of water.

The ability of plants to take water from the soils varies in an ascending scale from

hydrophytes, through mesophytes, to xerophytes. In a general way, the limit of available water within the plant coincides with the physical conditions of its habitat.

Herbaceous plants, both annuals and perennials, when affected by slow drought usually die in the following manner: The older leaves of the plant perish first, the younger ones living to the last. The finer roots die first, then the coarser ones, finally the stem, and last of all the growing point of the stem, or if the plant is a flowering one the immature fruit. Trees, shrubs, and perennial herbs lose their aerial organs first, the roots usually being the last part of the plant to die. Bulbous and tuberous plants, even when immature, form their bulbs and tubers quite rapidly when caused to die by drought.

Influence of the awns of grasses, S. TREYAKOV (*Khozyaĭne*, 1902, No. 6, pp. 188-191; *abs. in Zhur. Opuĭtn. Agron. [Jour. Expt. Landw.]*, 3 (1902), No. 2, pp. 239, 240).—The influence of the awns on the development of the grain in red winter bearded wheat was studied by the author at the Poltava experiment field. Two plats were selected, in one of which all the awns were removed from the spike as soon as they appeared, while upon the other they were allowed to remain. The ripening began 2 days earlier in the case of those spikes deprived of their awns. The yield of grain, as well as the ash analysis, is shown, from which the conclusion is drawn that the absence of awns is accompanied by a smaller-sized grain and by less weight. The grain from the awnless spikes was richer in ash but poorer in nitrogen and phosphorus. Comparisons were made with the figures obtained in this experiment, and the results of growing bearded and beardless varieties of wheat were found analogous in each case. By comparing the average yields of awned and awnless wheat for a number of years the author concludes that awned varieties, under the conditions of cultivation at the experimental field, gave smaller yields of grain, but the individual grain possessed a higher absolute weight, and the fluctuations of the bearded wheats are less than those of the beardless varieties.—P. FIREMAN.

Influence of the fluctuation of temperature on the respiration of seeds and embryos of wheat, KARCHEVSKI (*Mem. Warsaw Univ.*, 9 (1901), pp. 114; *abs. in Zhur. Opuĭtn. Agron. [Jour. Expt. Landw.]*, 3 (1902), No. 2, p. 241).—The investigations here reported were conducted to ascertain how the seeds and embryos of wheat are affected by being subjected to elevated temperatures. The subjects experimented upon were placed for 24 hours in water before the determination of the carbon dioxid exhalation was begun. As a result of 24 experiments the author concludes that the energy of carbon dioxid respiration is 12 times as great in the case of the embryos as in the seeds themselves. The preliminary drying of the embryos at temperatures of 62° for 24 hours does not exert any appreciable influence on the respiration. If heated to 70° C. a reduction is observed, and at 98.5° C. there is a complete cessation of the exhalation of carbon dioxid and death of the embryo. With the seeds no change takes place even when dried up to temperature of 91° C. A rapid fall in the respiration of carbon dioxid begins if dried for 24 hours at 98 to 105°, and at 112° death results. These figures were obtained with seeds and embryos which were subjected to elevated temperature in a dry condition. If the same temperatures are attained in water, the death point is found to be considerably lower.—P. FIREMAN.

Influence of light on the respiration of some of the lower fungi, N. A. MAXIMOW (*Centbl. Bakt. u. Par.*, 2. Abt., 9 (1902), Nos. 6-7, pp. 193-205; 8, pp. 261-272, figs. 2, *diagms.* 18).—The results of a prolonged series of experiments with *Aspergillus niger*, *Mucor stolonifer*, *Penicillium* sp., *Oidium lactis*, *Micrococcus prodigiosus*, and *Proteus vulgaris* are given. The organisms were grown in culture media, and the effect of light and darkness on the carbon dioxid production was determined. The experiments with *Aspergillus niger* and *Mucor stolonifer* are reported at considerable length. It was found in the case of *Aspergillus* that the influence of light on respiration was dependent upon the age of the fungus and the conditions of nutrition. With young,

well-nourished cultures light had no effect on respiration. With old cultures the action of light promoted respiration. The effect of light usually became apparent in about 30 minutes and continued as long as the conditions remained constant. By repeatedly changing from light to darkness the flasks in which the organisms were grown, the stimulating influence of the light was greatly diminished. With *Mucor stolonifer* light had a positive stimulating effect for the first half hour, but if continued much beyond that time it proved detrimental to the respiration of the mold.

Investigations on the respiration of plants, B. PLOVTVZEV (*Zap. Imp. Akad. Nauk*, 22 (1901), No. 7; *abs. in Zhur. Opuitn. Agron. [Jour. Expt. Landw.]*, 3 (1902), No. 2, pp. 233-237).—A critical review is given of investigations relating to the subject of plant respiration.—P. FIREMAN.

The irritability of stigmas as a means for the prevention of the germination of foreign pollen, W. BURCK (*Proc. Sec. Sci., Koninkl. Akad. Wetensch. Amsterdam*, 4 (1901-2), pp. 184-193).—The results of a study of the irritable stigmas of *Torenia fournieri* and of *Mimulus luteus* are given, in which comparisons are made with a number of other plants possessing broad stigmas which are more or less sensitive. As a result of these studies the author claims that the movements present in the stigmatic lips serve to protect the flowers against the entrance of foreign pollen. In a number of experiments he found that the pollen of other species would germinate upon the stigmas of a given plant, but by the rapid closing of sensitive stigmatic surfaces the liability to fecundation was greatly reduced. If pollen from the same species be placed upon the stigmatic surfaces the lobes closed and opened only after a considerable duration of time, if at all, while if mechanical stimulus or foreign pollen be present the stigmas reopen within a quarter of an hour.

The necessity of lime for seedlings, especially those grown at high temperatures, L. VON PORTHEIM (*Sitzber. K. Akad. Wiss. Math. Naturw. Cl. [Vienna]*, 110 (1901), No. 4, pp. 113-157).—After reviewing and discussing considerable literature on the rôle of lime in plant nutrition, the author gives an account of experiments with seedlings of peas, lentils, beans, vetches, castor beans, flax, buckwheat, poppy, hemp, sunflower, pine, larch, and various cereals to ascertain the effect of a lack of lime in the media in which the plants were grown. After sprouting the seed between blotters wet with distilled water, the seedlings were transferred to pots containing clay shale and nutrient solutions added that varied only in the presence or absence of calcium nitrate. The plants were watered from time to time with spring or distilled water, dependent on the presence of lime in the nutrient media used. The growth of the different seedlings was noticed daily, especially the effect of raising the temperature to from 30 to 35° C. In many cases, but not all, the development of the hypocotyl and roots was much greater in the pots containing lime. The peculiar feature of nearly all the experiments was the turning brown and dying of the roots of the seedlings grown in the pots which had received no lime. In the case of the leguminous seedlings this took place within a few days. All the plants after a time became weakened and diseased, and the time difference between the 2 lots was assumed to show the necessity for lime for that particular plant. Increasing the temperature showed a marked effect on the condition of the 2 lots of plants, those without lime apparently suffering the most.

According to the author, his experiments show that the presence or absence of lime is immaterial for seedlings of cress, sorrel, rye, barley, wheat, oats, larch, and pine. The injurious effect of the absence of lime, as shown by Schimper, is attributed to the great quantity of potassium oxalate which is deposited within plants grown in the absence of lime. A brief bibliography completes the paper.

The solvent power of plants for mineral phosphates (*Rev. Gén. Agron. [Lourain]*, 11 (1902), No. 7-8, pp. 337-341).—The results of an extended series of experiments with a large number of species of plants are given, from which it appears that the solvent power of mineral phosphates varies widely with different classes of

plants. The cereals and grasses seem to possess this power in a limited way and leguminous plants to a considerably increased degree. Cruciferous plants and buckwheat are able to dissolve the mineral phosphates quite readily, as are potatoes and some other crops. A knowledge of the ability of crops to render soluble the mineral phosphates in fertilizers is an advantage in determining what fertilizers to use.

The physiological rôle of nicotin in the tobacco plant, G. ALBO (*Contrib. Biol. Veg. Roy. Ist. Bot. Palermo*, 3 (1902), No. 1, pp. 69-91).—In the author's investigations on the rôle of nicotin in the tobacco plant he found that this substance does not occur in the seed, but a substance similar to solanin is abundant in the seed and during the process of germination aids materially in the development of the plant. When the young seedlings have become well established and assimilation has begun, nicotin appears in certain cells of the hypocotyl and in the leaves, and later the alkaloid is found distributed throughout all the tissues. The total amount of nicotin in a plant varies with the conditions under which the plant is grown. If of 2 plants cultivated side by side the top be cut from one and the other allowed to flower and mature its seed, the greatest amount of nicotin will be found in the plant which has been topped, in some cases amounting to 3 times as much as that found in the plant which is allowed to mature. The nicotin which is formed by the plant is carried to the seed and there transformed into solanin or some similar substance. The experiments conducted with plants in darkness and in atmospheres deprived of carbon dioxide seem to indicate that nicotin has its origin in the leaves and that it is one of the products dependent upon the assimilation by the plant. Nicotin, it is claimed as the result of the author's investigation, is either directly or indirectly concerned in the nutrition of the tobacco plant.

The biology of asexual reproduction of flowering plants, A. TERRACCIANO (*Contrib. Biol. Veg. Roy. Ist. Bot. Palermo*, 3 (1902), No. 1, pp. 1-68, pls. 6).—The asexual reproduction of phanerogams is held by the author to be a device on the part of many plants to provide against the possibility of a failure of reproduction through seed. Such plants are less plastic than those grown from seed, a fact often taken advantage of in grafting, budding, etc. The different forms and conditions under which asexual reproduction may take place are enumerated, and the various biological phenomena observed by the author are described. The author's investigations were made on a number of species of plants, many of which were cacti, euphorbias, etc. The anatomical structure and biological relationships between parent plant and offshoot are to be treated in a subsequent paper.

Root tubercles of *Datisca cannabina*, A. TROTTER (*Bul. Soc. Bot. Ital.*, 1902, No. 2-3, pp. 50-52; *abs. in Bot. Cnubl.*, 90 (1902), No. 8, p. 196).—A preliminary note is given describing root tubercles which have recently been studied by the author, and he shows that they are formed by masses of fundamental tissue which contains hypertrophied nuclei but little or no starch, and the principal content of the cells is made up of bacteria which greatly resemble those known as *Bacillus radicicola*.

Green hemiparasites, E. HEINRICHER (*Jahrb. Wiss. Bot. [Pringsheim]*, 37 (1902), No. 2, pp. 264-337, pls. 2; *abs. in Jour. Roy. Micros. Soc. [London]*, 1902, No. 4, pp. 451, 452).—Descriptions are given of culture experiments made with *Euphrasia* with a view of ascertaining whether the chemical properties of the host plant were prejudicial to the growth of the parasite. It was found that both *Euphorbia* and *Oxalis* serve equally well as host plants in spite of the widely different chemical qualities of their cell sap. The claim that monocotyledons serve exclusively as host plants for these semiparasites is shown to be wrong, the author cultivating 3 species on widely different host plants, obtaining perfect development in every case. It was also shown that a single individual may attach itself at the same time to the roots of at least 2 different hosts. Investigations were also made on the relation of nutrition to the general habit of the plants. Studies were undertaken to decide how far parasitism was capable of being replaced by a saprophytic habit, and it is shown that while a

portion of plants grown in river sand came to flower a much larger portion matured when grown in humus cultures.

The seed fungus of the darnel, E. M. FREEMAN (*Proc. Roy. Soc. [London]*, 71 (1902), No. 467, pp. 27-30).—The presence of a considerable layer of hyphæ about the seed of the darnel (*Lolium temulentum*) was shown by Guérin several years ago (E. S. R., 11, p. 906), but thus far nothing has been ascertained regarding the method of infection of the plant. The author has carried on a series of experiments and has ascertained that in addition to the well-known hyphal layer surrounding the aleurone, there is a patch of hyphæ just outside of and contiguous to the base of the scutellum. From this area can be traced an abundant mycelium which penetrates the growing point of the embryo in the seed and thus affects the young growing point. No trace of any spores has been found and their presence seems unnecessary to the ordinary life cycle of the fungus. Other varieties and species of *Lolium* occasionally contain a hyphal layer which is probably identical with that of the darnel. The fungus layer is found in a varying proportion of the grains. All attempts to obtain cultures of the nuclear hyphæ have failed, indicating either that the hyphæ have lost their vitality, or, what is believed to be more probable, they are too closely adapted to symbiotic life to allow of artificial cultivation. There is believed to be no reason for the supposition of any so-called mycoplasma in the embryo, as the fungus is nearly always present as distinct hyphæ.

ZOOLOGY.

Judging the benefits and injuries produced by insectivorous birds, K. ECKSTEIN (*Verhandl. V. Internat. Zool. Cong. Berlin, 1901*, pp. 512-519).—Attention is called to the serious difficulties connected with the problem of determining the economic relations of insectivorous birds. Many species of injurious insects upon which these birds feed have natural limitations to their distribution, and various natural enemies assist in holding these insects in check. The parasitic and predaceous insects as well as fungus and bacterial diseases and unfavorable climatic influences must be considered as factors of some importance. The problem of determining just how much benefit insectivorous birds produce by their feeding habits is therefore a difficult one. The author believes that the laws which have thus far been passed offering protection for certain species of birds and withholding it from others might be improved in numerous instances.

Birds and insects in relation to agriculture, E. H. FORBUSH (*Trans. Massachusetts Hort. Soc.*, 1902, I, pp. 95-101).—A popular discussion of the agency of birds in controlling the multiplication of injurious insects.

A partial bibliography of the economic relations of North American birds, C. M. WEED (*New Hampshire Sta. Tech. Bul.* 5, pp. 137-179).—The author has compiled a list of the more important works on American economic ornithology, from 1808 to 1901, inclusive. The number of titles listed is nearly 300 and the titles are arranged in their chronological order.

Measures to be adopted for bird protection in Egypt, W. I. BEY (*Jour. Khediv. Agr. Soc. and School Agr.*, 4 (1902), No. 6, pp. 247-252).—Under existing laws in Egypt the slaughter of all kinds of birds has proceeded at a rapid pace. The author believes that restrictions must be placed upon hunters in order that some of the more valuable insectivorous birds may be saved from destruction.

Birds of New Zealand, D. V. LUCAS (*Jour. and Proc. Hamilton Sci. Assoc.*, 1901-2, No. 18, pp. 20-29, figs. 4).—Notes are given on the habits and economic relations of the kea, cuckoo, crows, tui, huia, kiwi, and moa.

Destroying sparrows (*Agr. Gaz. New South Wales*, 13 (1902), No. 12, p. 1197).—The best results in killing English sparrows were obtained from dissolving 1 oz. strychnin in 14 fluid oz. absolute alcohol and 4 pts. hot water. After the solution is

cold, water is to be added to bring the quantity up to 4 gal. One bushel of wheat is then soaked for 48 hours in this solution and spread out in suitable situations.

Woodpeckers (*California Bd. Hort. Rpt. 1901-2*, pp. 175-178).—Popular notes on the habits of insects with special reference to their economic relations.

The quest of rabbit extermination and the question of disease (*Pastoralists' Rev.*, 12 (1902), Nos. 6, pp. 395, 396; 7, pp. 474, 475).—A review is given of the extensive investigations which were stimulated by the offer of \$125,000 made by the government of New South Wales in 1888 for a successful remedy in exterminating rabbits. While all of the nearly 1,500 plans which were proposed were unsuccessful, the author believes that better results may perhaps be obtained at present, and recommends that the Australian government offer a much larger reward for a satisfactory method of exterminating rabbits.

The plague of rats, T. SKSCHIVAN (*Centbl. Bakt. u. Par.*, 1. Abt., 33 (1903), No. 4, Orig., pp. 260-273).—Considerable interest attaches at present to the study of diseases which affect rats on account of the agency of these animals in transmitting contagious diseases, especially the bubonic plague. Three species of rats are influential in carrying infectious diseases; these are *Mus decumanus*, *M. rattus*, and *M. alexandrinus*. Notes are given on a number of diseases of rats resembling bubonic plague, and the author presents the details of post-mortem findings in 15 rats apparently dead of the plague. In order to secure a check upon the post-mortem examinations, guinea pigs were inoculated with the material obtained from these rats.

A bacillus pathogenic for the house rat, C. TOYAMA (*Centbl. Bakt. u. Par.*, 1. Abt., 33 (1903), No. 4, Orig., pp. 273-281).—Detailed notes are given on the post-mortem findings in rats which had died of apparently an infectious disease. A microscopic examination was made of material obtained from various organs of the dead rats. A number of inoculation experiments were made in mice and rats with material obtained from these cases and notes are given on the artificial infection thus produced. Death resulted in the majority of cases between from 5 to 53 days, with symptoms similar to those of spontaneous cases of the disease in rats. Notes are given on the behavior of the bacillus on various culture media. No capsules or spores could be detected, and the bacillus is motile. It is believed to be closely related to *Bacillus typhi murium*, but is considered as a distinct species.

Mouse and rat plague, E. WIENER (*Ztschr. Landw. Versuchsw. Oesterr.*, 5 (1902), No. 9, pp. 1009-1035).—The author presents a critical review of the various attempts which have been made to discover and isolate a pathogenic organism which can be used successfully in killing mice and rats. It is believed, as a result of the author's investigations, that the various organisms which have been experimented with and recommended for this purpose by different authors are all of the same species. A number of cultures which were received for testing during these experiments proved to be nonvirulent.

Infection with Trypanosoma, T. VON WASELEWSKI (*Verhandl. V. Internat. Zool. Cong. Berlin, 1901*, pp. 424-428).—A brief discussion is given of the means and effects of infection by various species of *Trypanosoma* in animals, especially in frogs and rats.

Twenty-fourth annual report of the South Australian Zoological and Acclimatization Society (*Rpt. South Australian Zool. and Acclim. Soc.*, 24 (1902), pp. 45, pls. 4).—Notes are given on the wild animals which have been collected at the Adelaide Zoological Garden and on the hygienic conditions which prevail among these animals. Brief descriptions are given of Burchell's zebra, Barbary sheep, and kangaroo, and a detailed list is presented of the various animals in the zoological garden at the present time.

Phytopathological observations with special regard to Vierlande near Hamburg, with contributions to the fauna of Hamburg, L. REH (*Sta. Pflanzenschutz, Hamburg*, 4 (1901-2), pp. 111-223, pl. 1).—Brief descriptive notes are given of Vierlande, with an account of excursions made through that country. The author

discusses the various diseases due to unknown causes, climatic conditions, parasitic fungi, and animals as observed during his excursions about Hamburg. The animal pests are classified into Mammals, birds, mollusks, insects, mites, and worms, and insects are further subdivided into families and smaller groups. A brief general account is presented of the means of combating these pests.

Zoological record, D. SHARP (*Zool. Rec.*, 38 (1901), pp. 1144).—As usual, the present volume of this publication contains a list of titles published on zoological subjects during the year covered by the report. The number of periodicals from which these titles were taken is more than 1,000. A list of these periodicals is given and the general bibliographical matter is arranged as previously, under the following heads: General subjects, mammalia, aves, reptilia, batrachia, pisces, tunicata, mollusca, brachiopoda, bryozoa, crustacea, arachnida, myriopoda, prototracheata, insecta, echinoderma, vermes, coelenterata, spongiae, and protozoa.

Index zoologicus, C. O. WATERHOUSE (*London: Zool. Soc. of London*, 1902, pp. VII + 421).—This index is prepared for the purpose of including an alphabetical list of the names of genera and subgenera proposed for use in zoology, as recorded in *Zoological Record*, 1880-1900, and other zoological generic names not included in the *Nomenclator Zoologicus* of S. H. Scudder. The number of new names indexed in the *Zoological Record* are tabulated for each year from 1880 to 1900. It is estimated that the total number of names included in this index is about 40,000, and that the total number of zoological generic names, exclusive of synonyms, is thus brought up to about 80,000.

Index-catalogue of medical and veterinary zoology, C. W. STILES and A. HASSALL (*U. S. Dept. Agr., Bureau of Animal Industry Bul. 39, pt. 2, pp. 47-198*).—In this part of the bulletin the author index of veterinary and medical zoology is continued and includes all names beginning with B.

Guide for collecting, preserving, and packing animals for the zoological museum in Berlin, MÖBITZ (*Anleitung zum Sammeln, Konservieren und Verpacken von Tieren für das zoologische Museum. Berlin: Zoological Museum, 1902, pp. 113, figs. 25*).—Notes are given on the approved methods of collecting, preserving, and packing animals of all kinds for shipment to the museum. These notes are prepared as a guide to travelers or colonial officials of the German Government who may wish to collect specimens for the museum.

Game laws for 1902, T. S. PALMER and H. W. OLDS (*U. S. Dept. Agr., Farmers' Bul. 160, pp. 56*).—This is a revised and condensed form of Bulletin 16, Division of Biological Survey (E. S. R., 13, p. 532).

METEOROLOGY.

Monthly Weather Review (*Mo. Weather Rev.*, 30 (1902), Nos. 10, pp. 473-510, figs. 2, charts 8; 11, pp. 511-552, figs. 4, charts 10; 12, pp. 553-602, figs. 37, charts 10).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of October, November, and December, 1902, recent papers bearing on meteorology, etc., these numbers contain the following articles and notes:

No. 10.—Special contributions on Cloudbursts, by A. D. Elmer; Does the Lightning Ever Strike the Ocean? by J. Trowbridge; The Climate of Baguio, Philippine Islands, by F. O. Stetson; Some Peculiarities in Frost Formation over the Coast Region of South Carolina, by L. N. Jesunofsky (p. 845); Cycles of Precipitation (illus.), by L. H. Murdoch (p. 845), and The Circumhorizontal Arc, by L. Besson; and notes on Weather Bureau men as instructors in meteorology, waterspout at Cape May, N. J., severe hailstorm at St. Louis, Mo., volcanic and atmospheric phenomena (illus.), and Robert Rubenson.

No. 11.—Special contributions on November Gales from the Great Lakes to the

Maritime Provinces, by B. C. Webber; Annual Wind Resultants (illus.), by T. H. Davis; and The Climatology and Water Power of Porto Rico, by W. H. Alexander; and notes on Tromholt's catalogue of Norwegian auroras, Maryland climatology, Samuel B. Pfanner, Australian droughts and the moon, shadow bands—scintillation—interference bands, meteorological stations in Africa, and analogous storms.

No. 12.—Special contributions on Studies on the Meteorological Effects of the Solar and Terrestrial Physical Processes (illus.), by F. H. Bigelow; Cloud Bursts, by H. H. Ten Broeck; An Explanation of Wireless Telegraphy (illus.), by A. H. Thiesen; and Radioactivity of Freshly Fallen Snow, by S. J. Allan; and notes on meteorology at the American Association, the Becquerel rays in meteorology, and H. H. Moore.

Some peculiarities in frost formation over the coast region of South Carolina, L. N. JESUNOFSKY (*Mo. Weather Rev.*, 30 (1902), No. 10, pp. 479-481).—The article records and discusses observations extending over a number of years on the occurrence of spring and autumn and winter frosts on the truck farms in the vicinity of Charleston. Injury done by frost in this locality varies widely in adjoining fields and even in different parts of the same field. Various explanations of this phenomenon have been offered, viz, difference in air drainage, excessive use of fertilizers, variations in ground water, warm air, currents, and salt air, are discussed, but none is shown to be satisfactory.

Cycles of precipitation, L. H. MURDOCH (*Mo. Weather Rev.*, 30 (1902), No. 10, pp. 482-485, fig. 1).—This article deals with cycles of precipitation at Salt Lake City and at other places in the United States. The author finds for Salt Lake City a dry cycle between 1827 and 1864, during which the average annual rainfall was about 15 in.; a wet cycle from 1865 to 1886, with an average annual precipitation of 18.42 in.; and from 1887 to 1901 a dry cycle during which the average annual precipitation was 15 in. From records for San Francisco, Sacramento, Denver, Omaha, St. Louis, Cincinnati, and Baltimore, it appears that the country west of the Rocky Mountains had its wettest cycle from 1866 to 1887, while the Middle Mississippi and Ohio valleys had the heaviest precipitation from 1840 to 1859. The present dry cycle is general from San Francisco to Baltimore. The author finds no relation between his rainfall curves and Wolfer's sun-spot tables, and concludes "that there is no known natural law by which we can predict the length of the present dry cycle."

Meteorology, J. B. HARRISON (*Rpt. Agr. Work Bol. Gard. [British Guiana], 1896-1901*, pp. 4-12).—Summaries are given of observations on the amount and composition (chlorin, ammonia, and nitrates) of the rainfall, on sunshine, and on the effects of the seasons on crop growth during the years 1896-1901. The mean rainfall for the period was 83.6 in.

"The weather during the years 1896-1901 . . . varied greatly from year to year, and while in no year was it consistently throughout the year favorable for either work in the field or for continued active growth or maturation of the sugar cane, in some of them, as in 1898, 1899, and 1900, serious interruptions to the growth and welfare of the sugar cane, as well as of all other crops, were caused by the occurrence of long-continued periods of drought. In the report last issued it was recorded that during a period of five years, of which 1893 was the climax, there had been a succession of years marked by exceedingly heavy rainfalls, averaging an annual fall of 124.47 in., and that during the years 1894 and 1895 the rain had been more nearly normal, amounting approximately to 84 in. per annum, as compared with a mean annual recorded fall of 94.35 in."

Arranging the data so as to show the distribution of rainfall over the wet seasons (December and January, May-August), the dry seasons (February, March, and April; September, October, and November), and the period of growth (December-September) it is found "that the best results with regard to sugar products have been as a rule . . . obtained with rainfalls of from 65 to 70 in. during the [period of

growth] and that the occurrence of heavy and well-distributed rainfalls in the months of May and June or June and July are of the first importance. . . . The rain during the period under review contributed an average of 121 lbs. of chlorine, equivalent to, in round numbers, 200 lbs. of common salt per acre, and 1.99 lbs. of combined nitrogen, the equivalent of, in round numbers, 8 lbs. of sulphate of ammonia."

The climatology of Africa, E. G. RAVENSTEIN ET AL. (*Rpt. British Assoc. Adv. Sci.*, 1901, pp. 383-395, figs. 2).—This is the tenth and final report of the committee appointed by the association to report on this subject, and gives summaries of observations during the year ended May 31, 1901, on pressure, temperature, precipitation, humidity, evaporation, prevailing wind, etc., at 21 stations in Africa, "including Asiut and Omdurman; Old Calabar; Blantyre, Lauderdale, Fort Johnston, and Nkata Bay, in Nyasaland; Kisimayu, Malindi, Lamu, Takaunga, Mombasa, and Shimon, on the coast of British East Africa; Machako's, Kitui, Nairobi, and Kikuyu, in the interior of that Protectorate; and from the four lake stations in Buganda." There are also added the results of 7 years' observations on the rainfall at Mengo (Buganda), taken from the unpublished journal of A. M. Mackay, and a table giving the rainfall since 1890 at a number of stations.

Rainfall and temperature at Pretoria, J. L. SOUTTER (*Transvaal Agr. Jour.*, 1 (1902), No. 1, pp. 53-56).—Summaries are given of observations on rainfall from July, 1891, to June, 1902, inclusive, and on shade temperature during the 15 months ended September 30, 1902.

Meteorological report of the State of Florida for the year 1901, A. J. MITCHELL (*Rpt. Comr. Agr. Florida, 1901 and 1902*, pp. 220-235).—This is a report by the director of the Florida section of the climate and crop service of the U. S. Weather Bureau on temperature, precipitation, cloudiness, wind movement, dates of first and last frosts, etc., at a large number of places in the State. The mean temperature during 1901 was 68.8° F., the precipitation 58.47 in.; the means for 10 years, including 1901, were 70.6° and 52.73 in., respectively.

Meteorological observations, W. B. ALWOOD (*Virginia Sta. Rpt. 1902*, pp. 10, 11).—Tables are given which show monthly averages of observations at Blacksburg, Va., on temperature, precipitation, direction of wind, and cloudiness for the calendar year 1902; and monthly means of temperature and precipitation during 10 years (1893-1902). The mean temperature for the year ended December 31, 1902, was 52° F., the precipitation 33.78 in.

Meteorological observations on Ben Nevis, A. BUCHAN ET AL. (*Rpt. British Assoc. Adv. Sci.*, 1901, pp. 54-60).—This is the report of the committee of the association appointed to cooperate with the Scottish Meteorological Society in making observations at the two Ben Nevis observatories, and gives summaries of observations during 1900 on pressure, temperature, rainfall, sunshine, cloudiness, wind movement, and casual phenomena.

Meteorological observations at the agricultural-chemical experiment station of Breslau, B. SCHULZE (*Jahresber. Thät. Agr. Chem. Vers. Stat., Provinz Schlesien, 1901-2*, pp. 5, 6, tables 15).—Detailed daily, monthly, and annual summaries are given of observations on pressure, temperature, humidity of the air, sunshine, wind movement, and rainfall for the period from January, 1901, to March, 1902, inclusive.

On the seasonal variation of the atmospheric temperature of the British Isles and its relation to wind direction, W. N. SHAW and R. W. COHEN (*Rpt. British Assoc. Adv. Sci.*, 1901, pp. 558-560).

On the effect of sea temperature upon the seasonal variation of air temperature of the British Isles, W. N. SHAW (*Rpt. British Assoc. Adv. Sci.*, 1901, pp. 560, 561).—An analysis of observations on atmospheric temperature "shows that there is a considerable lag in the occurrence of the seasonal variations of temperature

at coast stations as compared with inland stations, and a still greater lag in the variations of temperature in the sea itself.

The mean temperature of the atmosphere and the causes of glacial periods. H. N. DICKSON (*Rpt. British Assoc. Adv. Sci., 1901, pp. 722, 723*).

On the systematic exploration of the atmosphere at sea by means of kites. A. L. ROTCH (*Rpt. British Assoc. Adv. Sci., 1901, p. 724*).—See also E. S. R., 13, p. 626.

Recurrence of rain—The relation between the moon's motion in declination and the quantity of rain in New South Wales. H. C. RUSSELL (*Jour. and Proc. Roy. Soc. New South Wales, 35 (1901), pp. 113-115*).—An analysis of rainfall records is made which indicates that rainfall is abundant "when the moon is in certain degrees of her motion south, and when the moon begins to go north then droughty conditions prevail for seven or even eight years, a phenomena repeated for three periods of nineteen years each." The author believes that there is a law connecting the two phenomena.

Instructions for obtaining and tabulating records from recording instruments. C. F. MARVIN (*U. S. Dept. Agr., Weather Bureau Doc. 277, pp. 31, figs. 2*).—A second edition of this bulletin.

On the inverse relation of chlorin to rainfall. W. ACKROYD (*Rpt. British Assoc. Adv. Sci., 1901, p. 603*).—From an analysis of observations on the chlorin content of rainfall it "clearly appears that minimum amounts of rainfall are marked by maxima of chlorin contents, and vice versa."

Weather maps. W. N. SHAW (*Rpt. British Assoc. Adv. Sci., 1901, p. 725*).—This note refers to an exhibit of the daily weather maps of 23 countries.

International catalogue of scientific literature. F—Meteorology (*Internat. Cat. Sci. Lit., 6 (1902), pp. XIII+184*).—A partial list of references to the literature of meteorology, including terrestrial magnetism, appearing during 1901. The references to meteorological literature omitted from this volume are to be included in the next annual issue of the catalogue.

WATER—SOILS.

Contributions from the royal testing station for water supply and sewage disposal of Berlin. A. SCHMIDTMANN and C. GÜNTHER (*Mitt. Kgl. Prüfungsanstalt Wasser. u. Abw., Berlin, 1902, No. 1, pp. 166*).—These include the following papers: The Principles of the Biological Examination of Water with Reference to Flora and Fauna, by R. Kolkwitz and M. Marsson; Purification on the Filter in the Biological Process of Purification, and The Constituents of the Scum Which Forms on the Surface of Sewage in Tanks in Biological Purification Methods, by O. Emmerling; The So-called Biological Processes of Sewage Purification, by K. Thumm; Garbage Disposal with Special Reference to its Agricultural Utilization, by H. Thiesing; The Utilization of the Sewage Sludge of Cassel, by Höpfner and Paulmann; and An Automatic Zero Point Burette, by C. Zahn.

Purification of drinking water by distillation. G. COUPAN (*Jour. Agr. Prat., n. ser., 5 (1903), No. 8, pp. 255-259, figs. 4*).—A discussion of general principles and descriptions of various methods and forms of apparatus.

Artesian water in the State of Queensland, Australia. R. L. JACK (*Rpt. British Assoc. Adv. Sci., 1901, p. 641*).—An account is given of the artesian area and of borings for artesian water, one of which extended to a depth of 5,040 ft. The largest flow obtained was 6,000,000 gal. daily. The artesian area is estimated at 264,600 square miles.

The movements of underground waters of Northwest Yorkshire. W. W. WATTS ET AL. (*Rpt. British Assoc. Adv. Sci., 1901, pp. 337-339*).—This is the report of a committee of the association and gives the results of an inconclusive study by means of fluorescein of the underground course of a small stream.

On the distribution of chlorin in Yorkshire, II, W. ACKROYD (*Rpt. British Assoc. Adv. Sci., 1901, p. 603*).—As a result of many observations, it is shown that chlorin increases from 0.7 to 1 part per 100,000 of water in the west and northwest, where the rivers originate, to 1.7 to 2 in the east and southeast. The normal chlorin content apparently increases in the vicinity of manufacturing centers, and is also increased by the prevalence of high winds from the sea.

On the circulation of salt and its geological bearings, W. ACKROYD (*Rpt. British Assoc. Adv. Sci., 1901, pp. 654, 655*).—The bearing of the salt carried inland from the sea on estimates of the geological age of the earth and on the saltiness of inland lakes and salt hills is discussed.

On the supply of sodium and chlorin by the rivers to the sea, E. DEBUIS (*Proc. Sec. Sci., Koninkl. Akad. Wetensch. Amsterdam, 4 (1901-2), pp. 388-399*).

On the diffusion of water in humus soils, E. BLANCK (*Landw. Vers. Stat., 58 (1903), No. 1-2, pp. 145-160*).—A series of experiments is reported which shows that the presence of acid humus compounds in a soil hinders the diffusion of water, a condition which may be corrected by adding a neutralizing agent such as lime.

The soils of Dominica, F. WATTS (*Barbados: Imp. Dept. Agr. West Indies, 1903, pp. 32, figs. 25*).—Physical and chemical analyses of 23 samples of soil from different parts of the island are reported, with a discussion of the results and description of the method employed. In general the soils were found to contain only very moderate amounts of carbonates. They were generally deficient in phosphoric acid, but contained considerable amounts of assimilable potash.

The method followed in preparing the acid extract of the fine earth for chemical analysis was as follows: "Twenty grams of 'fine earth' are placed in a round-bottomed 250 cc. flask with 200 cc. of hydrochloric acid of specific gravity 1.115. A stopper (usually cork) is loosely inserted. The flask is placed in the water bath in the afternoon, the bath brought to boiling point, the lamp removed and the flask allowed to remain in the bath all night. Next morning the bath is brought to boiling by about 10 a. m., and maintained in that condition throughout the day. At 4 p. m. the lamp is removed and the flask allowed to remain in the bath all night. During the process of heating the flasks are repeatedly shaken. The following morning the contents of the flasks are removed, filtered, and the residue well washed; the filtrate, including the washings, is evaporated to dryness after the addition of a few drops of nitric acid. The residue is taken up with a little water containing a few drops of hydrochloric acid and again evaporated to dryness. After drying, it is again taken up with a little water and acid as before and filtered, washing well with warm water. After cooling the solution is made up to 500 cc."

Ordinary methods were employed in the determination of most of the constituents. In case of carbonates, however, a special process is described which it is claimed "is both simple and accurate, and allows relatively large quantities of soils to be taken for the determination when necessary," a consideration which is of special importance in case of volcanic soils, such as those of the West Indies. The method consists essentially of adding strong hydrochloric acid to a quantity of soil capable of yielding 50 to 100 cc. of lime (about 25 gm. in case of the soils examined), collecting the gas evolved over mercury by means of a simple Sprengel pump, and titrating with excess of barium hydrate and fifth-normal hydrochloric acid. The details of the method and of the apparatus needed are described.

Nitrogen was determined by the Kjeldahl method. No attempt was made to determine humus directly. Organic carbon was determined by the method of Cross and Bevan^a and humus calculated by multiplying carbon by 1.724. Assimilable phosphoric acid and potash were determined by Dyer's method. Osborne's method of mechanical analysis was employed.

^aJour. Chem. Soc. (Trans.), 53 (1888), p. 890.

Geology regarded in its economic application to agriculture by means of soil maps, J. R. KILROE (*Rpt. British Assoc. Adv. Sci.*, 1901, pp. 643-645).—This paper discusses the utilization of geological information in the valuation of land, the improvement of estates, and in schemes of irrigation and drainage, and explains how the drift maps of the British Geological Survey may be made more useful for this purpose.

The source of nitrogen in forest soil, R. G. ZON (*Pop. Sci. Mo.*, 62 (1903), No. 5, pp. 436-440).—A brief discussion of this subject based mainly upon the results of observations by E. Henry, of the University of Nancy, France, that freshly fallen leaves absorb atmospheric nitrogen in the process of decomposition.

The natural improvement of soils, E. B. VOORHEES (*Pennsylvania Dept. Agr. Bul.* 102, pp. 50, pls. 4).—A nontechnical discussion of facts and principles, explaining the chemical, physical, and biological differences in soils, the conservation of moisture, tillage, mulching, and the use of lime and leguminous plants in improving soils.

Studies on the distribution of lime in the soils of vineyards, J. DUFOUR and H. FAES (*Chron. Agr. Canton Vaud*, 15 (1902), Nos. 19, pp. 547-551; 20, pp. 576-579; 21, pp. 609-612; 23, pp. 655-661; 24, pp. 696-700).—The continuation and conclusion of an article part of which has already been noted (*E. S. R.*, 14, p. 231). Analyses with reference to lime content of the soils of a large number of Swiss vineyards are reported.

A contribution to the chemical study of peat soils, G. ONGARO (*Staz. Sper. Agr. Ital.*, 35 (1902), No. 11-12, pp. 897-909).—Analyses of a number of samples of peat soils are reported, with results of plat experiments on wheat and oats to determine their fertilizer requirements.

On the treatment of moor soils, G. GROTENFELT (*Finska Mosskult. Aarbok*, 1901, No. 1; *abs. in Svensk Mosskult. Tidskr.*, 16 (1902), No. 2, pp. 231-238).

Notes on the occurrence of phosphatic nodules and phosphate-bearing rock in the upper carboniferous limestone (Yoredale) series of the West Riding of Yorkshire and Westmoreland border, J. RHODES (*Rpt. British Assoc. Adv. Sci.*, 1901, p. 655).

A case for soil investigations, R. THIELE (*Centbl. Bakt. u. Par.*, 2. Abt., 9 (1902), No. 9, pp. 330-332, fig. 1).—A case filled with the necessary apparatus for the study of soil organisms is described.

FERTILIZERS.

Peat soil as a soil amendment, H. VON FEILITZEN (*Svensk Mosskult. Tidskr.*, 17 (1903), No. 1, pp. 11-19).—Experiments conducted on sandy, clayey, and moorland soils showed that applications of humus or peat soil rich in lime and in nitrogen exert a very favorable influence on the productive capacity of these soils, largely through the mechanical improvement of the soils resulting from the increase in their humus contents, since a complete fertilization with nitrogen, phosphoric acid, potash, and lime was given in all cases. The experiments were conducted with four different crops—peas, oats, barley, and potatoes. If the yields harvested on the plats which did not receive a dressing with peat soil be placed at 100, the relative yields obtained as the result of applications of 66 to 264 cubic meters of peat soil per hectare (1,000 to 3,800 cu. ft. per acre), were as follows: Peas on sandy soil, seed 105, vines and pods 103, on clay soil 108 and 110, respectively; barley on clay soil, grain 125, straw and chaff 129; oats on sandy soil, grain 134, straw and chaff 129, on clay soil 118 and 154, respectively; potatoes on poor sandy soil 243 in 1899 and 143 in 1900, on sandy soil (old field) 109 in 1900, and on high moor soil 128 in 1900 and 113 in 1901.

The trials do not furnish decisive evidence as to the quantities of peat that should

be applied, since the yields obtained increased with the quantities added, but in practice applications of 100 to 150 cubic meters per hectare (1,400 to 2,150 cu. ft. per acre) may be considered ample. The effect of the peat can be readily seen during several succeeding years.—F. W. WOLL.

Ammoniacal and nitric nitrogen, S. HALS (*Tidsskr. Norske Landbr.*, 9 (1902), No. 5, pp. 212-225).—A résumé of the subject is given with an account of two series of experiments conducted by the author at Darmstadt Experiment Station, for the purpose of studying the question whether a moist, loamy soil is able to fix all nitrogen applied in form of ammonium sulphate. The experiments, which were made on small samples of soil in the laboratory, with and without addition of lime and water, showed that a loss of nitrogen through evaporation of ammonia can take place in a loamy soil rich in lime when small quantities of ammonium sulphate are added and the soil is exposed to the sun and wind. Liming and addition of water (increased evaporation of water) increase the evaporation of ammonia, and this is larger when the ammonium sulphate is strewn on the surface of the soil than when mixed with it.

In the change of ammonia to nitric acid in the soil a portion of the nitrogen has been found to disappear. According to Wagner, only 89 per cent is recovered. The result of the author's experiment would suggest that the loss is due to evaporation of ammonia. A nitrification experiment was made with a loamy soil containing 1.21 per cent lime (in the dry matter) and 15 per cent water, the soil being placed in glass cylinders provided with ground glass stoppers which were connected with a U-tube for the absorption of ammonia that might escape. The evaporation of water from the soil was thus reduced to a minimum and the ammonia that might escape could be collected and determined quantitatively. The results of the experiments showed that under these conditions no loss of nitrogen took place. During the 30 days in which the experiments lasted the ammoniacal nitrogen was not completely changed into nitric nitrogen, there being about 7 per cent of nitrogen unaccounted for, which in all probability had been changed into organic compounds.—F. W. WOLL.

The utilization of atmospheric nitrogen by agricultural plants, M. GERLACH (*Jahrb. Deut. Landw. Gesell.*, 17 (1902), pp. 20-25).—A general discussion.

Studies in nitrification, G. S. FRAPS (*Amer. Chem. Jour.*, 29 (1903), No. 3, pp. 225-241, figs. 2).—This has been noted from another source (*E. S. R.*, 14, p. 110).

Notes on nitrification organisms, W. OMELIANSKI (*Centbl. Bakt. u. Par.*, 2, Abt., 9 (1902), Nos. 1-2, p. 63; 3-4, p. 113).—Experiments are reported which go to show that the nitrification organisms do not cause the oxidation of incompletely oxidized mineral compounds, such as sodium sulphite and phosphite, and do not produce oxidizing enzymes.

Are there bacteria which assimilate free nitrogen or is this a chemical process? A. A. BONNEMA (*Chem. Ztg.*, 27 (1903), No. 14, pp. 148-150).—It is suggested that the fixation of free nitrogen in the soil may be due to the catalytic action of iron hydroxid.

On the nitrogen content of the seed of lupines used as fertilizer, N. PASERINI (*Staz. Sper. Agr. Ital.*, 35 (1902), No. 11-12, pp. 887-896).—Analyses of the seed of different kinds of lupines and experiments with the seeds as a fertilizer for wheat in comparison with various other nitrogenous fertilizers are reported which show the high value of the seed as a nitrogenous fertilizer.

The preservation of barnyard manure, T. PFEIFFER (*Jahrb. Deut. Landw. Gesell.*, 17 (1902), pp. 166-177).—A general discussion.

Compost heap and its management, M. SAUL (*Deut. Landw. Presse*, 30 (1903), No. 9, pp. 67, 68).—A brief note advising especially against deep plowing under of manure.

On the utilization of night soil in European cities, J. SEBELIEN (*Tidsskr. Norske Landbr.*, 9 (1902), No. 4, pp. 149-186).

On experiments with manure and artificial fertilizers, O. OMRE (*Tidsskr. Norske Landbr.*, 9 (1902), No. 6, pp. 245-263).

On the manuring of the soil in Algiers and Tunis, G. RYF (*Bul. Dir. Agr. et Com. [Tunis]*, 8 (1903), No 26, pp. 69-78).—A brief general discussion of the care, management, and use on different crops of farm manures.

On the organization of local fertilizer experiments in European countries, A. RINDELL (*Landbr. Styr. Meddel.*, 1902, No. 41, pp. 44).—A report on the organization of cooperative and other fertilizer experiments in the Scandinavian countries, England, and France.

The supplying of the phosphoric acid requirements of plants, P. WAGNER (*Jahrb. Deut. Landw. Gesell.*, 17 (1902), pp. 26-30).—A general discussion of this subject.

Fertilizer experiments with phosphates, 1900-01, O. REITNAIR (*Ztschr. Landw. Versuchsw. Oesterr.*, 6 (1903), No. 2, pp. 95-194, pl. 1).—Previously noted from another source (*E. S. R.*, 14, p. 647).

On the question of the influence of a physiologically acid salt in rendering phosphorite soluble, I. SCHULOV (*Zhur. Opuitn. Agron. [Jour. Expt. Landw.]*, 3 (1902), No. 6, pp. 711-719, fig. 1).—In continuation of previous experiments (*E. S. R.*, 14, p. 343), the author made pot experiments with oats to determine whether the action of ammonium salts in rendering phosphorite soluble is due to changes (separation of base and acid) occurring in the soil or after the salts are absorbed by the plant. In one series of experiments the ammonium salt and the phosphorite were intimately mixed in the soil, in another series double pots were used in which the ammonium salt and the phosphorite were kept separate, though each was accessible to the plant. The results quite clearly indicate that the changes which result in increasing the assimilability of the phosphorite occur only when the ammonium salt is intimately mixed with the phosphorite in the soil.

Algiers phosphate against Thomas phosphate, A. YSTGAARD (*Norsk Landmandsblad*, 21 (1902), No. 46, pp. 556, 557).

Pot experiments with fertilizers, B. SCHULZE (*Jahresber. Thät. Agr. Chem. Vers. Stat., Provinz Schlesien, 1901-2*, pp. 21-32).—These included comparative tests during 2 years of kainit, muriate of potash and sulphate of potash on oats and barley, in which the largest yield and utilization of potash by the crop was shown in case of the muriate, sulphate being second as regards yield and third as regards utilization of potash by the crop; studies of the action of the phosphoric acid of steamed bone with and without the simultaneous application of lime, which showed the depressing effect of the latter on the former in experiments with oats; similar experiments which indicated that the nitrogen of steamed bone is somewhat more effective on oats than that of ammonium sulphate; experiments which showed a low effectiveness for the nitrogen of ground leather on white mustard as compared with ammonium sulphate; experiments on oats and peas which showed that acetylene gas residue has no injurious effect and produces fully as large yields as calcium carbonate; comparative tests which showed that the water-soluble phosphoric acid of superphosphate is more effective in increasing the yield of potatoes than the citrate-soluble acid of Thomas slag; comparative trials on oats, in which ammonium sulphate applied one-half before seeding and one-sixth in each of 3 top-dressings during the growing season gave better results than nitrate of soda applied one-half before seeding and one-third in each of 2 top-dressings afterwards; and a reference to experiments on the replacement of potash by soda.

Fertilizer experiments with kainit and 40 per cent potash salt, B. SCHULZE (*Jahresber. Thät. Agr. Chem. Vers. Stat., Provinz Schlesien, 1901-2*, pp. 6-20).—Experiments on sugar beets, potatoes, barley, and grass lands are reported. During the 3 years over which the experiments have extended the 2 potash salts gave about equally good results on sugar beets, the kainit being somewhat more profitable in

dry seasons, the 40 per cent salt in wet seasons. In a wet year both salts reduced the yield of potatoes, but in dry years moderate applications of either salt increased the yield sufficiently in most cases to overbalance the depressions in starch content which uniformly resulted from the application of the salts. In dry years the kainit gave best results on barley. The results on grass lands were inconclusive, although on dry lands and in dry seasons kainit apparently gave best returns.

On further results of the comparative fertilizer experiments with kainit and 40 per cent potash salt, W. SCHNEIDEWIND (*Jahrb. Deut. Landw. Gesell.*, 17 (1902), pp. 30-33).—A general discussion of this subject, which is more fully presented elsewhere (E. S. R., 14, p. 22).

Arrangements for irrigation and fertilizing on the royal domain of Grafenwerth on the Rhine, R. SCHROER (*Deut. Landw. Presse*, 30 (1903), No. 1, p. 3, figs. 5).

Fertilizer department, B. E. McLIN and R. E. ROSE (*Rpt. Comr. Agr. Florida, 1901 and 1902*, pp. 104-112, App., pp. 1-70).—An account is given of the conduct and results of the fertilizer inspection in the State, with analyses of a large number of samples of fertilizers.

Fifth biennial report of the Missouri Agricultural Experiment Station on the enforcement of the fertilizer-control law, H. J. WATERS (*Missouri Sta. Circ. of Information* 16, pp. 16).—A statement of receipts and disbursements, with analyses and valuations of 134 samples of fertilizers examined during 1901.

FIELD CROPS.

Field experiments at Lauchstädt, W. SCHNEIDEWIND, D. MEYER, and W. GRÖBLER (*Landw. Jahrb.*, 31 (1902), No. 5-6, pp. 826-908, 963-968).—The results of fertilizer and variety tests from 1898 to 1901, inclusive, are reported at some length.

Maximum yields of root crops were obtained only when barnyard manure was applied in conjunction with commercial fertilizers. This result is attributed to the mechanical effect of barnyard manure on the soil which favors the growth of plants and a consequent greater utilization of plant food. Although a very heavy application of nitrate of soda was made the quantity of nitrogen taken up by the plants was increased when barnyard manure was applied in addition to the nitrate. A heavy application of barnyard manure alone gave higher yields of turnips and potatoes than a heavy application of nitrogen, phosphoric acid, and potash in the form of commercial fertilizers. It was observed that a quantity of nitrogen taken up from barnyard manure produced more substance than an equal quantity taken up from nitrate of soda. The nitrogen from nitrate of soda enters largely into the production of the leaf and is used in this connection to a greater extent than the nitrogen from barnyard manure. From the average results of these tests, the returns from 100 kg. of deep stall manure and barnyard manure for turnips and potatoes, taking its residual effect on a succeeding crop of barley or wheat into consideration, varied from 29 to 35 cts. with stall manure and from 22½ to 27 cts. with barnyard manure. The variation with each was due to differences in the price of turnips and potatoes.

Deep stall manure gave larger yields than barnyard manure, but the differences were not in proportion to its larger quantity of readily soluble nitrogen compounds. Attention is called to the fact that the losses from deep stall manure when spread upon the field were greater than from barnyard manure which has already sustained considerable losses before its application, and that hence deep stall manure is more economically applied in quantities not furnishing more nitrogen than is taken up by the growing crop. In an experiment where 40,000 kg. of deep stall and barnyard manure were applied in connection with growing sugar beets, followed by barley in rotation, the nitrogen used by the crops was on an average 26.7 per cent of the quantity furnished in the deep stall manure and 23.8 per cent of the quantity given in

the manure taken from the barnyard. The authors believe that with a lighter application a larger percentage of the nitrogen in the deep stall manure would have been utilized.

In another series of experiments it was found that liquid manure or nitrate of soda gave a larger increase in yield on soil poor in nitrogen when applied alone than when used with either a mixture of fresh manure and straw or with straw alone. When liquid manure or nitrate was applied alone a larger percentage of the nitrogen furnished was recovered in the crop than in the other case. This is explained by reference to the fact that fresh organic substances, such as the manure and the straw in this case, serve as a food material for certain soil bacteria and withdraw the nitrogen, which is in the form of nitrates, ammonia, and amids, from the use of the plants. This action necessarily results in a diminished yield on soils not containing an adequate amount of available nitrogen. These experiments were conducted in the first place with mustard, a very quickly growing plant, but later the same results, though not so marked, were obtained with cereals. The residual effect of the manure for the second and third years was only slightly favorable, while straw still had a detrimental effect the second and gave but a very slight increase in yield the third year. Fresh manure and straw did not decrease the yield on soils which furnished sufficient nitrogen for both the growing crop and the denitrifying bacteria which live on the undecomposed material. It sometimes occurs that when nitrogen is plentiful the use of fresh manure and straw increases the yield through its beneficial mechanical effect on the soil. It was also found that plants will take up as much nitrogen from nitrate of soda applied with barnyard manure, especially if well rotted, as when the nitrate is given alone, because the denitrifying organisms use the nitrogen compounds already formed in the manure. The authors conclude that the best yields of root crops are obtained when barnyard manure is used, but these results are not contradictory to the foregoing, because in these tests a surplus of available nitrogen existed in the soil and the barnyard manure used was not fresh. However, if the nitrogen supply of the soil had not been sufficient, then the use of fresh manure would also have been detrimental to roots.

Among different green manures a mixture of beans, peas, and vetches was most effective. The seed of this mixture, consisting of 50 per cent of beans, and 25 per cent each of peas and vetches, was sown after early barley or with winter oats at the rate of 250 kg. per hectare. The average annual financial returns per hectare from this method of green manuring amounted to \$15. The quality of sugar beets was slightly lowered by green manuring. All nitrogenous fertilizers tend to lower the quality of beets and potatoes, but this loss is said to be largely outweighed by the increase in yield, provided the application is not too heavy.

A number of check plats which received no nitrogen gave good returns and showed no decrease in yields during the several years the experiments were in progress. This result shows that the soil conditions did not allow heavy applications of nitrogen. On sugar beet and potato plats, fertilized at the rate of 2 cwt. each of nitrate of soda and 200 cwt. and 133 cwt. of barnyard manure, respectively, $\frac{1}{2}$ of the nitrate was applied at a loss. In experiments with wheat on plats of this same kind of soil which had not received barnyard manure for 2 years, only $\frac{1}{2}$ and $\frac{2}{3}$ cwt. of sulphate of ammonia per morgen (about 0.6 acre), applied in the fall and spring, respectively, was profitable. Where the preceding crop of potatoes had received barnyard manure only $\frac{1}{2}$ cwt. in the spring in addition to the $\frac{1}{2}$ cwt. given in the fall gave a profitable return. Barley on this soil without barnyard manure for 2 years used only from $\frac{1}{2}$ to $\frac{3}{4}$ cwt. of ammonia per morgen with profit. It was found that where the preceding crop of beets had received barnyard manure, barley needed no application of nitrogen.

The use of phosphoric acid was necessary in all cases. An application of 20 to 25 lbs. per morgen for cereals and of 25 to 30 lbs. for root crops is considered adequate.

The results of the tests indicate that heavier applications would not be profitable. Superphosphate gave better results than Thomas slag. The sugar content of beets and the starch content of potatoes was not increased by fertilizing with phosphoric acid.

Owing to the large amounts of potash given the soil in barnyard manure, potash salts were not profitable for either cereals or root crops when applied with barnyard manure. Potash had no detrimental effect on the quality of sugar beets, but it lowered the starch content of potatoes. On the soil in question 40 per cent potash salt is considered preferable to kainit and the following quantities per morgen are recommended: Sugar beets 1.5 cwt., potatoes 1 cwt., and cereals 0.75 cwt. The use of potash every year did not seem advisable.

Variety tests with square head wheats show the best yields from Beseler Square Head No. 3. Among other varieties the wheat known as "Salischer Sandweizen" gave the largest yield. This variety also proved richest in protein and best for bread making of all the varieties grown. Hanna barley stood first among spring varieties and Bestehorn Giant Winter barley among winter varieties. Eckendorfer Mammut was the earliest variety of barley under experiment. Beseler No. 1 and No. 2 were the best yielding varieties of oats.

The average yield of dry matter in field beets for a series of years amounted to 9,900 kg. per hectare, while sugar beets, given high fertilizer applications, yielded 12,000 kg. In 1901, however, field beets and sugar beets yielded about equal quantities of dry matter. It is stated that 20 lbs. of sugar beets furnish about the same quantity of nutritive material as 50 lbs. of field beets. Owing to their low moisture content sugar beets keep much better in storage than field beets. The nutritive value of the dry matter in either variety is determined by the sugar content.

Extensive tables are given showing the composition of the crops under test and the quantities of plant food they withdrew from the soil.

Fertilizer experiments on meadows, EDLER (*Deut. Landw. Presse*, 30 (1903), No. 16, p. 128, figs. 4).—Thirty-one cooperative tests with kainit, Thomas slag, and nitrate of soda as fertilizers for meadows are reported. The different fertilizers were applied alone and in different combinations at the rate of 1,000, 800, and 100 kg. per hectare, respectively. The combined use of the fertilizers gave the best results, and the author concludes that the application of nitrogen in addition to potash and phosphoric acid on meadows is more profitable than is generally supposed.

Kainit and 40 per cent potash salts as fertilizers for cereals, H. BACHMANN (*Deut. Landw. Presse*, 30 (1903), No. 15, p. 120).—The results of cooperative fertilizer experiments are reported in tabular form. The use of 40 per cent potash salts applied in the spring gave a larger increase in the yield of oats and a smaller increase in the yield of straw than kainit. Lime given in connection with these potash salts did not change the relation of the results. With sugar beets kainit applied in the fall was more effective than 40 per cent potash salt, but when the applications were made in the spring kainit was the less effective of the 2 fertilizers. Kainit gave the better financial returns and in all cases showed the greater residual effect.

Variety tests of barley and oats, C. FRUWIRTH (*Vergleichende Anbau-Versuche mit verschiedenen Gerste und Hafersorten*. Pflingen: Friedrich Find, 1902, pp. 68).—The varieties of barley under test included Trotha Chevalier, Hanna, Selchower, Princess, and Goldthorpe, and those of oats Albhafer, Duppaner, Sechsaenter, Heine Ertragreichster, Heine Trauben, Beseler, and Carter Golden. Each variety is described at some length, together with the results obtained in the experiments. The experiments extended over a period of 3 years.

Studies of Bohemian varieties of barley, O. KAMBERSKÝ (*Ztschr. Landw. Versuchsw. Oesterr.*, 6 (1903), No. 1, pp. 1-21, pls. 2).—The results of studies in this line by various investigators are reviewed and 80 different varieties and forms of barley

grown in Bohemia are classified under botanically recognized species and varieties. The different kinds are described and compared.

Bermuda grass, J. FIELDS (*Oklahoma Sta. Bul. 55*, pp. 11, figs. 3).—A brief popular bulletin on Bermuda grass in Oklahoma. A description of the grass and its culture is given and the experience of a number of experiment stations and of farmers throughout Oklahoma, who have tested it, is noted. "Of all the grasses tried on the station farm, Bermuda alone has shown the qualities which must be possessed by a pasture grass in Oklahoma. . . . It should be started only on lawns or on land intended for permanent pasture and should be kept out of fields intended for cultivation."

Bermuda grass, J. S. NEWMAN (*South Carolina Sta. Bul. 76*, pp. 6).—A brief popular bulletin on the culture of Bermuda grass. A description of the plant is given and notes on its artificial propagation, the protection of the young plants from shade, and the method of destroying the sod are presented.

Improvement of red clover, M. FISCHER (*Fühling's Landw. Ztg.*, 52 (1903), No. 2, pp. 55-59).—The author reviews the results of experiments in the improvement of red clover conducted by himself and others, and concludes that for the purpose of shortening the growing period selection of yellow seed from early maturing dark green plants with many dark red inflorescences should be made. In order to increase the size of the plant it is recommended that the seeds of an intense violet color from slowly developing light green plants with comparatively few heads light red in color be selected.

Corn culture, R. J. REDDING (*Georgia Sta. Bul. 58*, pp. 197-218).—Experiments here described are in continuation of work previously noted (E. S. R., 14, p. 842). Meteorological data for the year and the growing season are given in tables, and notes on the use of fertilizers in corn culture are appended.

Among 13 varieties tested in 1892 the most prolific were Bradberry Improved, Marlboro, and Sander Improved, yielding 12.95, 12.86, and 12.66 bu. per acre, respectively. The least productive variety, Allen Big White, yielded only 3.60 bu. per acre. Owing to a rather poor soil and a dry season the yields were low. A test of early varieties was made on more fertile soil, and the results obtained are judged more reliable than those in the experiment just described. In this test the yields ranged from 26.84 to 35.51 bu. per acre with Marlboro Prolific, Weekley Improved, and Cocke Prolific in the order given leading in productiveness.

A comparison of planting corn on the beds and in the water furrow resulted in favor of the beds, although the season was very dry. These results and those of previous years indicate that it is not advisable to plant in the water furrow. Thorough preparation of the soil as compared with ordinary preparation gave an increase in yield of only 1.16 bu. per acre, which was hardly enough to pay for the extra work. Experiments in cultivation during this dry season showed that the yield increased in proportion to the frequency of cultivation. Cultivating every week in the dry season is considered better than cultivating thrice in succession every 3 weeks or twice every 2 weeks.

Fertilizer tests were made with the different applications of uniform cost, but the drought prevented the utilization of the fertilizers applied. Attention is called to the financial risk of using fertilizers when the crop is grown on dry uplands.

Methods of corn breeding, C. G. HOPKINS (*Illinois Sta. Bul. 82*, pp. 525-539, figs. 2).—This has been noted from another source (E. S. R., 14, p. 321).

Cotton, A. OPPEL (*Die Baumwolle. Leipzig: Duncker & Humblot, 1902*, pp. 745, figs. 236).—This work gives the history of cotton, describes the cotton plant and its culture, and discusses the uses of the fiber, the by-products of the plant, and the relation of cotton culture to commerce and economic conditions. In addition the cotton industry in each cotton-growing country of the world is treated separately. An extensive bibliography on cotton is given.

Experiments with hemp, V. V. VINER (*Khozyaĭne*, 1901, No. 47-48; rev. in *Zhur. Oputn. Agron.* [*Jour. Expt. Landw.*], 3 (1902), No. 2, pp. 248, 249).—Fertilizer, variety, and seeding tests with hemp are reported. The results of the fertilizer experiments indicated that phosphoric acid was the only element capable of producing a marked improvement in the growth. Nitrogen stood second in effectiveness and potash last. It is said that the plant food requirements of hemp resemble those of the grasses, with the exception that hemp prefers nitrogen to potash. The average crops from plats without fertilizers with applications of phosphoric acid, potash, and nitrogen alone, and with a combined application of the 3 elements, bore the same relation to each other as 178, 236, 164, 203, and 268, respectively. Phosphoric acid equally affected the formation of stems, fiber, and seed. Potash mainly improved the yield of seed, and nitrogen increased the yield of fiber. The results further showed that hemp readily assimilates the phosphoric acid from bone meal.

From observations in connection with the seeding experiments it is concluded that on poor soils the crop should be thickly sown.—P. FIREMAN.

Novel system of potato production (*Gardening*, 11 (1903), No. 252, p. 183, figs. 2).—An account is given of securing new potatoes from old seed left in caves at the end of the year. The old potatoes were placed in one end of a dark cellar on the ground and partially covered over with sifted sand. In this position they produced a large number of small tubers, but scarcely any leaves or stems. By a proper succession of layering, young potatoes were gathered throughout the autumn and winter.

Rape as a forage crop, A. S. HITCHCOCK (*U. S. Dept. Agr., Farmers' Bul.* 164, pp. 16, fig. 1).—This bulletin gives a description of rape and the varieties which have come into prominence; outlines the value of the plant for feeding purposes and its uses as a catch crop, weed destroyer, vegetable, and cover crop; and discusses in a general way the culture of the crop, with notes on soil requirements and preparation, seeding, cultivation, and harvesting. Brief notes on rape growing in several States are also presented.

Culture and composition of rice, G. D'UTRA (*Bol. Agr. São Paulo*, 3. ser., 1902, No. 9, pp. 571-583).—A general discussion on the culture of the crop is given, and the results of analyses of samples of rice grown in different localities in southern Brazil are shown in tables.

Root crops in Montana, R. S. SHAW (*Montana Sta. Bul.* 40, pp. 20).—This bulletin gives popular descriptions of the culture of sugar beets, mangels, carrots, turnips, and potatoes under Montana conditions. In addition to treating each crop individually a general discussion on growing root crops, including notes, are given on soil preparation, seeding, harvesting, and storing. The bulletin also gives directions for the preparation of the seed and for treatment to prevent scab.

Sugar beets, F. W. TRAPHAGEN (*Montana Sta. Bul.* 41, pp. 8).—The results of analyses of sugar beets grown by farmers in cooperation with the station in 1902 are briefly presented. The number of samples is considered insufficient for drawing general conclusions. The richest sample contained 24 per cent of sugar in the juice. Results for several years have indicated that the sugar-manufacturing campaign in Montana could begin about the middle of September. This season excellent results were obtained, although very little water, and in some instances none, reached the crop during the growing season.

Sugar-beet speculation, A. B. LECKENBY and R. WITHEYCOMBE (*Eastern Oregon Sta. Bul.* 1, pp. 11, figs. 10).—The injuries resulting from boring sugar beets are discussed and illustrated. A study of these injurious effects was made by boring 2 mother beets and allowing them to grow with their centers thus destroyed. Two of the samples contained more than 22 per cent of sugar, but the season's growth after boring contained less than 10 per cent in one, while the other contained no sugar at all. All of the bored beets grew into highly distorted forms.

A table is given showing the quality of the beets selected according to certain leaf characters, and the author recommends such selection in the improvement of the beet.

A number of beets were divided into 6 concentric rings and each ring analyzed. The results show that the outer portions contained the least sugar, while the portion halfway between the center and the outer portion was richest.

Notes on the selection of seed beets are summarized as follows: "Select only those with flat tops, single crowns, smooth bulbs, good shoulders, growing well underground with short and firm leafstalks bearing flat yellowish green leaves, bulbs well supplied with feeding roots coming from well defined long dimples in cheek of beet and only those rich in sugar."

Late growth of sugar beets, A. G. DOYARENKO (*Zhur. Opušn. Agron. [Jour. Expt. Landw.]*, 3 (1902), No. 4, pp. 516-518).—Analyses of sugar beets harvested September 1, 10, 20, and 30 showed that the last sample harvested represented an increase in yield of 20.3 per cent and that the quality of the beets gradually deteriorated from the earlier to the later date of harvesting.—P. FIREMAN.

Experiments with sugar cane, J. B. HARRISON (*Rpt. Agr. Work Bot. Gard. [British Guiana]*, 1896-1901, pp. 12-133).—Results of variety and fertilizer experiments with sugar cane for the years 1896-1901 are reported. The detailed results are given at some length in tabular form.

The analyses and yields of old varieties of cane are given, and the record of each variety is briefly noted. The tests with seedling canes showed that the richness of the parent cane does not indicate the probable richness of the seedling or canes propagated from it by cuttings. In a few cases seedlings exhibited a tendency to approximate the sugar content of the parent plant. The percentage of non-sugars in the juice seemed also free from hereditary influences. The glucose ratio and in part the quotient of purity were governed by the degree of maturity. The size of individual canes did not seem to affect the size of the offspring, but the average size of the parent varieties closely governed the size of the seedlings. Although most seedlings from seed of seedling varieties showed deterioration, some gave considerable promise. The seeds from seedlings proved more fertile than those from old varieties. The seedlings from older varieties generally showed a marked tendency to variation, while in those from seedling varieties this tendency was not so obvious and many of them came fairly true to the parent cane. The variation in color, size, and sugar content was greater in the seedlings from striped canes than in those from self-colored canes.

Experiments with different fertilizers, including lime, were conducted on very heavy clay soils. The supply of nitrogen in the forms of sulphate of ammonia, nitrate of soda, raw guano, and dried blood mainly governed the increase in yield due to the use of fertilizers. When not more than 40 lbs. of nitrogen were applied per acre, sulphate of ammonia and nitrate of soda gave practically the same results, but in general the author considers the sulphate preferable. Dried blood and raw guano were inferior to each of these forms. In applications furnishing more than 40 lbs. of nitrogen per acre on alluvial soils sulphate of ammonia was the best nitrogenous fertilizer. The use of 200 lbs. of sulphate of ammonia or 250 lbs. of nitrate of soda per acre gave better results than heavier dressings. In general, dressings of from 200 to 300 lbs. of the sulphate seemed the most profitable applications of nitrogen.

The yield of plant canes was increased by the use of superphosphate of lime applied with nitrogen and potash. The effect of phosphates on ratoon crops was hardly perceptible, and the author recommends restricting the use of phosphates to plant canes and manuring ratoon crops with nitrogen only. Thomas slag gave better results than superphosphate of lime. Mineral phosphates proved unprofitable. Potash, either in the form of the sulphate or the nitrate, exerted little or no effect. Lime gave largely increased yields which seemed to be due mainly to the mechanical effect on the soil.

As in previous experiments the use of either phosphoric acid, potash, or lime in connection with other fertilizers did not have a favorable influence on the sugar content. Nitrogenous fertilizers retarded maturity and consequently reduced the sugar content, but this loss was more than offset by the increase in yield.

Sugar-cane culture (*New York: German Kali Works, pp. 68, figs. 19*).—This treatise is a popular outline of sugar-cane culture in different countries. In this connection climate, drainage, irrigation, varieties, seedlings, soils, and fertilizers are discussed, and the composition of sugar cane and of different materials used in fertilizing the soil for the culture of this crop is given.

Fertilizer experiments with tobacco in Deli, D. J. HISSINK (*Meded. 'S. Lands Plantentuin, 1902, No. 60, pp. 171*).—Cooperative fertilizer experiments with tobacco were carried on in 1901, and the results are here reported at some length. On well-drained land and under favorable weather conditions the chlorin and sulphuric acid given in the fertilizer showed no detrimental effect. The results on sandy soils containing considerable humus indicate that in favorable seasons practically no fertilizers were necessary. A small quantity of nitrate given each individual plant when set out gave good returns. For clay soils the author especially recommends the use of nitrogen in nitrate form. Phosphoric acid was found to be very effective upon black, red, and clay soils. Although the tobacco plant contains but little phosphoric acid, the Deli soils were most in need of this element. A fertilizer containing 10 per cent each of potash and phosphoric acid is recommended for all soils. The nitrogen content of fertilizers for black and red soils, according to the author, should be from 4 to 5 per cent, and for clay soils 5 per cent, with 0.4 of the quantity in the nitrate form. In connection with 0.5 gm. of nitrogen and 0.75 gm. of phosphoric acid per plant from 1 to 2 gm. of potash gave the best results. Analyses of the soils on which the tests were made are tabulated.

Agricultural botanical report for 1901, J. ERIKSSON (*K. Landt. Akad. Handl. Tidskr., 41 (1902), No. 2, pp. 112-134*).—A report is given of investigations on the hardness of different varieties of wheat grown at the experimental grounds of the Royal Academy of Sweden, upon investigations of cereal rusts, etc. Of the 146 varieties of winter wheat under observation from 1890 to 1901 the following foreign varieties attained the highest rank: Urtoba, Graf Walderdorffscher, Kaiser, and Grevenhagener.—F. W. WOLL.

Manual of tropical agriculture, H. A. A. NICHOLLS, trans. by H. PITTIER (*Manual de agricultura tropical. San José, Costa Rica: Tipografía Nacional, 1901, pp. 244*).—The English edition has been previously noted (E. S. R., 13, p. 1105).

HORTICULTURE.

Vegetable gardening in the mountain glades, L. C. CORBETT and K. C. DAVIS (*West Virginia Sta. Bul. 81, pp. 356-386, pls. 6*).—The mountain glades of West Virginia are described as depressions at high altitudes in the Allegheny Mountains, varying in extent from a few to several thousand acres, into which the rich soil from the surrounding elevations has been washed by mountain streams and rains. They are usually wet and rather level. The soil is a muck rich in organic matter with some fine silt and underlaid with clay at a depth of 15 to 18 in. In its natural state it is overgrown with alders and other bushes. When brought under cultivation it requires drainage and will produce good crops of hay, wheat, corn, and buckwheat without fertilizers.

The work here recorded consists of records of the yields obtained on these glade soils during 3 seasons with cabbage, onions, squashes, and celery. These crops were grown with lime, complete commercial fertilizers in varying proportions, and barnyard manure, respectively. Some plats were left unfertilized for controls. The barnyard manure was used only during the last 2 seasons. Complete cultural directions

are included for all these crops. Good yields and vegetables of excellent quality were secured on all the differently treated plats each year of the experiment. Unusually large yields were obtained with cabbage, onions, and squashes, even when no fertilizers were used. The use of lime invariably resulted in increased yields over the control plats and in many instances gave as good or even better results than were obtained with commercial fertilizers. Of 23 varieties of cabbage grown Filderkraut, Louisville Drumhead, and Acme Flat Dutch gave the heaviest yields and proved desirable for both local and general market. Late cabbage appears to be more satisfactorily grown on these glade soils than earlier varieties.

With onions stable manure applied at the rate of 20 tons per acre resulted in the heaviest yields. The onions were grown continuously for the 3 seasons on the same plats, and the yields obtained the third season were considerably less than those obtained in either of the preceding years. Nothing was gained by seeding onions in a hotbed and transplanting to the open field over seeding in the field on the same date the seed was sown in the hotbed. The Southport strains of onions were found best suited to the cultural conditions of the glade lands. Southport White Globe was the best of the white varieties. Among the red onions the Red Weathersfield proved the most satisfactory in all respects. Philadelphia Silver Skin did not keep well.

In the culture of squashes the use of pieces of mosquito netting 18 in. square to place over the hills while the young plants were getting started is recommended as a protection against the striped cucumber beetle or squash bugs. A small wooden pin 6 in. in height is placed in the center of the hill, the netting thrown over it to form a tent, and the sides fastened down with dirt.

The results obtained with celery while the least satisfactory obtained with any of the vegetables grown, were nevertheless very good. Further work with this crop will be carried on.

Garden vegetables, O. M. MORRIS (*Oklahoma Sta. Bul. 56, pp. 14*).—The desirability of a garden on every farm is noted, and an account given of the culture, and in a number of cases of tests of varieties, of tomatoes, eggplants, onions, lettuce, radishes, salsify, beans, and peas.

As a result of the variety tests with tomatoes, extending now over a period of 3 years, the following varieties are recommended: Atlantic Prize, Beauty, Dwarf Aristocrat, Early Minnesota, Early Ruby, Favorite, Ignatum, Kansas Standard, Perfection, Ponderosa, Stone, and Trophy. All of these varieties are briefly described.

Only 3 varieties of eggplants have been successfully grown at the station. These are Fordhook Improved Spineless, New York Large Purple, and White Pearl. All of these varieties require about 100 days to come to maturity. The White Pearl has been found most productive.

In the growing of onions it has been found cheaper to grow the crop from seed than to plant out sets. Starting the seed in a seed bed and transplanting has regularly resulted in poor crops, owing largely to the soil being too dry at the time of transplanting in the early spring. The best 6 varieties recommended for general planting in Oklahoma are Australian Brown, Giant Red Rocca, Michigan or Ohio Globe, Pink Prizetaker, Prizetaker, and Southport Red Globe.

At the station lettuce has been successfully grown only in early spring. In some seasons when there is plenty of rain in the fall a late crop can also be secured with but little trouble. The curly leaf lettuces seem to give better satisfaction as a class than the head varieties. Of the curly leaf sorts Grand Rapids, Early Curled Silesian, Black Seeded Simpson, and Simpson Early Curled are considered about the best varieties, and of the head-lettuce sorts Early Prize Head, Silver Ball, Paris White Cos, and New York.

The Valentine varieties of beans are considered desirable for green or snap beans;

Large White Marrow and White Kidney for dry beans; and Golden Wax, Dwarf Black Wax, and Refugee Wax the best among the wax or yellow podded beans.

Among the peas Tom Thumb, Little Gem, Telephone, and White Marrowfat are, respectively, recommended in their season.

Effect of acetylene gaslight on plant growth, F. W. RANE (*New Hampshire Sta. Tech. Bul.* 4, pp. 8, figs. 7).—The effect of acetylene gaslight on the growth of a number of vegetables in the greenhouse has been experimentally determined during parts of two seasons. The light was obtained from a 10-lb. Acetogen generator having a cluster of 8 burners and a large 20-in. reflector. In the first experiment the lights were turned on April 4 and allowed to run each night until May 1. It appeared to be more or less effective upon the growth of beets, spinach, and cress, but its influence was less evident upon peas, tomatoes, and potatoes. Lettuce grown under the light was a trifle taller and somewhat more tender.

In the next experiment the lights were started in the greenhouse on January 1 and ran each night until February 15. This time the lettuce under the light grew considerably taller and was more tender than that grown in darkness. Beans, parsley, radishes, and coleus were also a little taller and somewhat more slender under the light. Corn also grew taller under the light, but was more stocky and had a better color in the dark. Fourteen heads of lettuce grown under the light weighed but $\frac{1}{4}$ lb. more than 14 heads grown under like conditions except in darkness.

The general conclusions are drawn that "most plants tend toward a taller growth under the light. It is doubtful whether this light can be used in the greenhouse from an economic standpoint for growing plants alone. While its effect is marked in the dark days of winter, little difference seems to be shown at other seasons of the year, when there is more sunshine."

The utilization of mineral matter by grafted plants, L. DANIEL and V. THOMAS (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 13, pp. 509-512).—The amount of a nutritive solution absorbed by 2 varieties of beans grown naturally and grafted on each other reciprocally have been determined experimentally. The results show that transpiration was much greater in the control plants than in the grafted plants. The control plants were also much more injuriously affected by chlorosis. The amount of nutritive material absorbed by the grafted plants was slightly less than in the control plants.

Radishes, parsnips, carrots, and salsify, E. S. BROWN (*Amer. Gard.*, 24 (1903), No. 427, pp. 135-137, figs. 7).—An account of variety tests of radishes, parsnips, carrots, and salsify on American Gardening trial grounds in 1902, with descriptive notes on the better varieties in each case.

Cabbages and cauliflowers (*Amer. Gard.*, 24 (1903), No. 429, pp. 166-168, figs. 4).—An account of the culture of cabbages and cauliflowers at the American Gardening trial grounds, with descriptions of 10 varieties of cabbages and 5 of cauliflowers.

Celery, E. S. BROWN (*Amer. Gard.*, 24 (1903), No. 428, pp. 152-154, figs. 5).—An account of the growth of several varieties of celery in the American Gardening trial grounds, with brief descriptive and cultural notes on 15 varieties.

The Dutch brined vegetable industry, R. F. CRAWFORD (*London: Bd. Agr.*, 1902, pp. 32, pls. 6, figs. 3).—An account is given of the culture and pickling of onions, gherkins, and cauliflower in Holland, with notes on methods of cooperation among Dutch market gardeners, and an account of Dutch market gardening schools. The appendix contains the regulations governing some of the cooperative associations of market gardeners in Holland and a complete syllabus of the lectures at the horticultural and market garden school at Boskoop.

Silverskin onions are the ones used for pickling in Holland. These are grown on clay soil about 3 ft. above the level of the dikes. About 40 tons of cow dung per acre

is used. The seed is sown at the rate of 56 lbs. per acre. The average crop is about 112 bu. In pickling the onions about 44 lbs. of salt is used to 330 lbs. of onions. Gherkins yield about 280 bu. per acre. Two crops of cauliflower are grown each season. From 4,500 to 5,000 plants are set per acre.

Vegetables containing iron. H. KÜHL (*Pharm. Ztg.*, 46 (1901), p. 608; *abs. in Ztschr. Untersuch. Nahr. u. Genussmitl.*, 5 (1902), No. 23, p. 1155).—Spinach was grown in soil treated with freshly precipitated iron hydroxid. The crop was freed from soil by washing and dried, yielding 30 gm. of dry matter containing 0.372 gm. iron in the ash.

Tests of table beets and mangel-wurzels. E. S. BROWN (*Amer. Gard.*, 24 (1903), No. 426, pp. 118, 119).—An account of a test of varieties of table beets and mangel-wurzels, with descriptive notes on 7 of the former and 2 of the latter.

An experiment in ginseng culture. G. C. BUTZ (*Pennsylvania Sta. Bul.* 62, pp. 14, pls. 2).—In 1897 the author secured 138 2-year-old cultivated ginseng roots, 100 native plants, and 300 seeds. These were planted and the data obtained for the 5 years up to 1902 are recorded. The native roots planted were small, of many shapes, and varied from 3 to 15 years of age, as shown by wrinkles on the roots. The 2-year-old cultivated roots were obtained from a dealer in ginseng roots. They were slender and plump, resembling young parsnips, and measured from 4 to 7 in. in length. Having been taken from cultivated soil, they had preserved in a large part all of their rootlets and thus differed from the native roots, which had been broken to a considerable extent in digging.

A ginseng bed was prepared by adding about 3 in. of woods earth to a clay soil and spading thoroughly 10 in. deep. The roots were planted 8 in. apart each way, using a planter's dibble 10 in. long for the purpose. The top of the root was placed 2 in. below the surface of the soil. The seeds used were planted in shallow drills 1 in. apart and covered with an inch of fine soil. Artificial shade was afforded the plants by a lath screen nailed to a framework 6 ft. high.

The after care of the plants consisted in mulching the beds with forest leaves and brush upon the approach of winter and removing this in springtime. The soil was kept loose during the summer and weeds were removed by two or three hoeings. As the seed ripened it was harvested and stratified. All the roots were harvested in October, 1902. At that time it was found that there had been a loss during the 5 years of 14 per cent of the cultivated plants, 48 per cent of the native plants, and 91 per cent of the seedling plants. During the last 4 years of the experiment there had been harvested 11,447 seeds from the cultivated plants, 1,223 seeds from the native plants, and 989 seeds from the seedlings sown. "The number of seeds per seed-bearing plant in 1902 averaged 55 on the cultivated plants, 17 on native plants, and 30 on seedling plants."

The total yield of roots as dug was 14.8 lbs. of cultivated roots, 3.2 lbs. of native roots, and 1.8 lbs. of roots from the seedlings. The roots were then trimmed and washed and all the rootlets under the thickness of a slate pencil which would have dried into mere brittle hairs were removed. The total weights were then reduced to 12.6 lbs. of cultivated roots, 2.5 lbs. of native roots, and 1.3 lbs. of seedling roots. The roots were then dried by subjecting them to an artificial temperature of 100 to 120° F. using the heat from a steam radiator. It required 19 days to dry the roots in good shape. It is stated that the usual way of drying the roots is to spread them on trays or tables in the sun. This requires from 6 to 8 weeks. The cultivated roots as dried weighed 4.66 lbs. or 37.1 per cent of their original weight; the native roots weighed 0.84 lb. or 34.62 per cent of their original weight. The cultivated roots brought \$8.50 per pound or a total of \$43.03. The native roots sold for \$6 per pound and brought \$4.87.

Using the data obtained in this experiment, with the 138 cultivated plants grown

Large White Marrow and White Kidney for dry beans; and Golden Wax, Dwarf Black Wax, and Refugee Wax the best among the wax or yellow podded beans.

Among the peas Tom Thumb, Little Gem, Telephone, and White Marrowfat are, respectively, recommended in their season.

Effect of acetylene gaslight on plant growth, F. W. RANE (*New Hampshire Sta. Tech. Bul.* 4, pp. 8, figs. 7).—The effect of acetylene gaslight on the growth of a number of vegetables in the greenhouse has been experimentally determined during parts of two seasons. The light was obtained from a 10-lb. Acetogen generator having a cluster of 8 burners and a large 20-in. reflector. In the first experiment the lights were turned on April 4 and allowed to run each night until May 1. It appeared to be more or less effective upon the growth of beets, spinach, and cress, but its influence was less evident upon peas, tomatoes, and potatoes. Lettuce grown under the light was a trifle taller and somewhat more tender.

In the next experiment the lights were started in the greenhouse on January 1 and ran each night until February 15. This time the lettuce under the light grew considerably taller and was more tender than that grown in darkness. Beans, parsley, radishes, and coleus were also a little taller and somewhat more slender under the light. Corn also grew taller under the light, but was more stocky and had a better color in the dark. Fourteen heads of lettuce grown under the light weighed but $\frac{1}{4}$ lb. more than 14 heads grown under like conditions except in darkness.

The general conclusions are drawn that "most plants tend toward a taller growth under the light. It is doubtful whether this light can be used in the greenhouse from an economic standpoint for growing plants alone. While its effect is marked in the dark days of winter, little difference seems to be shown at other seasons of the year, when there is more sunshine."

The utilization of mineral matter by grafted plants, L. DANIEL and V. THOMAS (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 13, pp. 509-512).—The amount of a nutritive solution absorbed by 2 varieties of beans grown naturally and grafted on each other reciprocally have been determined experimentally. The results show that transpiration was much greater in the control plants than in the grafted plants. The control plants were also much more injuriously affected by chlorosis. The amount of nutritive material absorbed by the grafted plants was slightly less than in the control plants.

Radishes, parsnips, carrots, and salsify, E. S. BROWN (*Amer. Gard.*, 24 (1903), No. 427, pp. 135-137, figs. 7).—An account of variety tests of radishes, parsnips, carrots, and salsify on American Gardening trial grounds in 1902, with descriptive notes on the better varieties in each case.

Cabbages and cauliflowers (*Amer. Gard.*, 24 (1903), No. 429, pp. 166-168, figs. 4).—An account of the culture of cabbages and cauliflowers at the American Gardening trial grounds, with descriptions of 10 varieties of cabbages and 5 of cauliflowers.

Celery, E. S. BROWN (*Amer. Gard.*, 24 (1903), No. 428, pp. 152-154, figs. 5).—An account of the growth of several varieties of celery in the American Gardening trial grounds, with brief descriptive and cultural notes on 15 varieties.

The Dutch brined vegetable industry, R. F. CRAWFORD (*London: Bd. Agr.*, 1902, pp. 32, pls. 6, figs. 3).—An account is given of the culture and pickling of onions, gherkins, and cauliflower in Holland, with notes on methods of cooperation among Dutch market gardeners, and an account of Dutch market gardening schools. The appendix contains the regulations governing some of the cooperative associations of market gardeners in Holland and a complete syllabus of the lectures at the horticultural and market garden school at Boskoop.

Silverskin onions are the ones used for pickling in Holland. These are grown on clay soil about 3 ft. above the level of the dikes. About 40 tons of cow dung per acre

is used. The seed is sown at the rate of 56 lbs. per acre. The average crop is about 112 bu. In pickling the onions about 44 lbs. of salt is used to 330 lbs. of onions. Gherkins yield about 280 bu. per acre. Two crops of cauliflower are grown each season. From 4,500 to 5,000 plants are set per acre.

Vegetables containing iron. H. KÜHL (*Pharm. Ztg.*, 46 (1901), p. 608; *abs. in Ztschr. Untersuch. Nahr. u. Genussmit.*, 5 (1902), No. 23, p. 1155).—Spinach was grown in soil treated with freshly precipitated iron hydroxid. The crop was freed from soil by washing and dried, yielding 30 gm. of dry matter containing 0.372 gm. iron in the ash.

Tests of table beets and mangel-wurzels. E. S. BROWN (*Amer. Gard.*, 24 (1903), No. 426, pp. 118, 119).—An account of a test of varieties of table beets and mangel-wurzels, with descriptive notes on 7 of the former and 2 of the latter.

An experiment in ginseng culture. G. C. BUTZ (*Pennsylvania Sta. Bul.* 62, pp. 14, pls. 2).—In 1897 the author secured 138 2-year-old cultivated ginseng roots, 100 native plants, and 300 seeds. These were planted and the data obtained for the 5 years up to 1902 are recorded. The native roots planted were small, of many shapes, and varied from 3 to 15 years of age, as shown by wrinkles on the roots. The 2-year-old cultivated roots were obtained from a dealer in ginseng roots. They were slender and plump, resembling young parsnips, and measured from 4 to 7 in. in length. Having been taken from cultivated soil, they had preserved in a large part all of their rootlets and thus differed from the native roots, which had been broken to a considerable extent in digging.

A ginseng bed was prepared by adding about 3 in. of woods earth to a clay soil and spading thoroughly 10 in. deep. The roots were planted 8 in. apart each way, using a planter's dibble 10 in. long for the purpose. The top of the root was placed 2 in. below the surface of the soil. The seeds used were planted in shallow drills 1 in. apart and covered with an inch of fine soil. Artificial shade was afforded the plants by a lath screen nailed to a framework 6 ft. high.

The after care of the plants consisted in mulching the beds with forest leaves and brush upon the approach of winter and removing this in springtime. The soil was kept loose during the summer and weeds were removed by two or three hoeings. As the seed ripened it was harvested and stratified. All the roots were harvested in October, 1902. At that time it was found that there had been a loss during the 5 years of 14 per cent of the cultivated plants, 48 per cent of the native plants, and 91 per cent of the seedling plants. During the last 4 years of the experiment there had been harvested 11,447 seeds from the cultivated plants, 1,223 seeds from the native plants, and 989 seeds from the seedlings sown. "The number of seeds per seed-bearing plant in 1902 averaged 55 on the cultivated plants, 17 on native plants, and 30 on seedling plants."

The total yield of roots as dug was 14.8 lbs. of cultivated roots, 3.2 lbs. of native roots, and 1.8 lbs. of roots from the seedlings. The roots were then trimmed and washed and all the rootlets under the thickness of a slate pencil which would have dried into mere brittle hairs were removed. The total weights were then reduced to 12.6 lbs. of cultivated roots, 2.5 lbs. of native roots, and 1.3 lbs. of seedling roots. The roots were then dried by subjecting them to an artificial temperature of 100 to 120° F. using the heat from a steam radiator. It required 19 days to dry the roots in good shape. It is stated that the usual way of drying the roots is to spread them on trays or tables in the sun. This requires from 6 to 8 weeks. The cultivated roots as dried weighed 4.66 lbs. or 37.1 per cent of their original weight; the native roots weighed 0.84 lb. or 34.62 per cent of their original weight. The cultivated roots brought \$8.50 per pound or a total of \$43.03. The native roots sold for \$6 per pound and brought \$4.87.

Using the data obtained in this experiment, with the 138 cultivated plants grown

on $\frac{1}{580}$ of an acre as a basis, the author estimates that the cost of growing an acre of ginseng 5 years would amount to \$9,249, distributed as follows:

80,040 plants, at 10 cents.....	\$8,004
Lath for screen roof, posts, boards for cross-bars and braces, setting posts, and carpentry.....	645
Planting, preparing soil, weeding and mulching for five years, digging roots, washing and drying crop	600

The receipts from an acre at the end of 5 years would be 2,900 lbs. of dried roots worth, at \$8.50 per pound, \$24,650. This gives a net profit in 5 years of \$15,401, without taking into consideration interest on money invested, the cost or rental of the land, etc. The bulletin concludes with a brief account of the more common enemies of ginseng.

Ginseng; its cultivation, harvesting, marketing, and market value, with a short account of its history and botany, M. G. KAINS (*New York: Orange Judd Co., 1903, n. ed., pp. 142, figs. 24*).—This is the second edition of this work, which has been enlarged to more than twice its former size and brought up to date. The increase in size is due largely to a discussion of the present status of the industry.

Notes from the trial grounds, E. S. BROWN (*Amer. Gard., 24 (1903), No. 425, pp. 103, 104, figs. 2*).—Notes are given on the growth of varieties of muskmelons and watermelons at the American Gardening trial grounds in New York. Eleven varieties of muskmelons and 4 of watermelons are briefly described.

Practical suggestions for fruit growers, H. P. GOULD (*U. S. Dept. Agr., Farmers' Bul. 161, pp. 28, figs. 8*).—This bulletin "is intended to be a practical presentation of principles rather than a description of methods." Such problems as location, soil, varieties, stock, pruning, fertilizing, tillage, cover crops, marketing, spraying, etc., are popularly discussed.

Peach growing in West Virginia, K. C. DAVIS (*West Virginia Sta. Bul. 82, pp. 389-441, pl. 1, figs. 21, maps 4*).—An account of the development and present status of the peach industry in West Virginia, including descriptions of the methods followed by the best peach growers of the State in setting out peach orchards, cultivating them, planting them with catch crops, thinning the fruit, combating insect and fungus pests, picking, packing, sorting, shipping, etc. Maps are given showing where peaches are now grown on a commercial scale within the State, where they have been successfully grown for home use, and the areas recommended for trial of peaches.

Some cooperative fertilizer experiments conducted by the station with commercial growers indicate that for Romney shales a complete fertilizer compounded in the proportion of 60 to 80 oz. of dissolved boneblack, 20 to 30 oz. of muriate of potash, and 20 to 30 oz. of nitrate of soda, and applied at the rate of 4 or 5 lbs. per tree for the first 5 years of the growth of the orchard, is likely to give very satisfactory results. Trees thus treated hold their leaves longer and fruit later than trees not fertilized. Applications containing 1 or 2 lbs. of muriate of potash, but omitting either the nitrate or the dissolved boneblack, did little or no good and in some cases were even harmful.

"More than 2 lbs. of potash per tree even killed the trees in several instances. Light applications of potash with some acid phosphate, in form of South Carolina rock or otherwise, produced the best colored fruit. Results indicate that the dates of ripening can be controlled to a limited extent by certain applications now being tested. When applied alone, bone meal gives better growth than dissolved bone. Thomas slag, while difficult to obtain, gives no better results than South Carolina rock."

As to the best varieties to plant, the following list, recommended by one of the oldest and largest peach growers of the State, is given:

(1) Southern Early; (2) Mountain Rose, Champion; (3) Oldmixon Free, Stump-the-World; (4) Reeves Favorite, Captain Ede; (5) Elberta; (6) Crawford Late, Fox Seedling; (7) Smock, Ford Late, Pickett Late; (8) Bonanza, Heath Cling, Leavy Late Cling; (9) Salway, and (10) Bilyeu. The varieties are noted in the order of their ripening, which in 1901 ranged from August 8 to October 19. Elberta is also mentioned as a great success, standing prolonged drought well and enduring a wet season.

An account is included of some trial shipments in 1901 of peaches and pears by one of the larger growers of the State to England. Five carriers of peaches and 3 of pears netted back to the growers \$19.50. According to New York quotations at the time these same fruits in the New York market would have returned but \$6.75, from which express, commission, cartage, etc., would have to be deducted.

The coloring matter and sugar of apricots, A. DESMOULIÈRE (*Ann. Chim. Analyt.*, 7 (1902), pp. 323, 324; *abs. in Analyst*, 27 (1902), No. 320, p. 325).—According to the author's analyses, apricots which were not completely ripe contained 3.13 per cent saccharose, 2.38 per cent invert sugar, and 0.77 per cent dextrose. Similar values for the ripe fruit were 3.81, 2.30, and 0.35 per cent. From the apricots pounded with water a liquid was obtained containing a yellow coloring matter which could be extracted by an acid or alkaline solution of amyl alcohol. This coloring matter on the addition of a drop of sulphuric acid gave an indigo blue color changing to brownish violet, an action identical with that of carotin, the yellow coloring matter of the carrot.

Culture of the citrus in California, B. M. LELONG ET AL. (*Sacramento: State Bd. Hort.*, 1902, pp. 267, figs. 148).—This work has been revised by the State Board of Horticulture to include present day methods of citrus culture in California.

The new method of curing lemons (*California Cult.*, 20 (1903), No. 5, p. 65, figs. 4).—The author states that in the California orchard of the Limoneira Ranch Company all lemons are thoroughly washed as soon as they are picked. This adds greatly to the appearance of the fruit, and if done as soon as the fruit is picked does not injure its quality. The fruit is dried under cover and not in the sun. Illustrations are given of the washing machines and packing house.

Limes at Dominica (*Agr. News [Barbados]*, 2 (1903), No. 21, p. 37).—Analyses of recently ripe fruits of the ordinary lime, a new spineless variety, and the Villa Franca or Sicily lemon, grown at the botanic station at Dominica, show the citric acid content of these varieties to be as follows: Ordinary lime, 13.22 oz. of citric acid per gallon; spineless lime, 13.8 oz.; and Sicily lemon, 11.05 oz. per gallon. The corresponding grains of citric acid per ounce of acid are as follows: 36.15, 37.73, and 30.22, respectively.

The formation of acid in lemons, E. LEUSCHER (*Ztschr. Oeffentl. Chem.*, 8 (1902), pp. 25-27; *abs. in Ztschr. Untersuch. Nahr. u. Genussm.*, 6 (1903), No. 1, p. 30).—The variety Eureka, in Jamaica, was found to weigh on an average 174 gm., and yield 78 cc. of juice containing 7.43 per cent of free citric acid.

Olive oil tests, W. J. ALLEN (*Agr. Gaz. New South Wales*, 13 (1902), No. 12, pp. 1212, 1213, pls. 3).—Tests have been made of a number of varieties of olives for oil production. Great differences were noticed between different varieties in the amount of oil furnished by the same quantity of fruit. Some varieties produced 8 to 10 times as much oil as other varieties. The proper selection of varieties, therefore, is a matter of considerable importance in oil production. The 2 varieties Correggiola and Pleureur were the best of a number of varieties tested and about equal in oil production. Next in order of merit were Boutillane, Pigale, and Dr. Fiaschi. Gros Redondeau was classed as a low-grade olive for oil production, while such varieties as Amellau, Bouquettier, Macrocarpa, Cucca, and Blanquette are not worth planting as oil producers. For both pickling and oil Correggiola and Pigale are recommended, though the latter proved a light bearer during the season of 1902. Another variety

not included in the test, but which is considered a good cropper and a particularly good oil producer, is Hardy Mammoth. Data relative to the date of gathering, the oil produced, and the size of the crop are tabulated for 11 varieties of olives.

The banana, CAZARD (*Bul. Agr. Algérie et Tunisie*, 9 (1903), No. 2, pp. 32-39).—An account of the origin of the banana, methods of planting, manuring, irrigating, packing, etc.

Pineapple culture, I. A. H. BENSON (*Queensland Agr. Jour.*, 12 (1903), No. 2, pp. 123-127).—The author states that so far as Australia is concerned the pineapple industry is practically confined to Queensland. The best fruits are grown in a climate in which the average annual temperature is under 70° and the average rainfall only 58 in. The most important pineapple district in Queensland is the Brisbane district, though good pines are produced in several other localities. The soils vary from a rich red or chocolate "scrub" to those poor, thin, and sandy. In the Brisbane district the soils are generally of a loamy nature. Directions are given for selecting the soil and site for pineapples.

Pineapples, cultivation, C. E. SMITH (*Agr. Jour. and Min. Rec. [Natal]*, 6 (1903), No. 3, pp. 83-89).—An account of the culture of pineapples in Jamaica, including notes on the insects and diseases affecting the plants.

The mango in Porto Rico, G. N. COLLINS (*U. S. Dept. Agr., Bureau of Plant Industry Bul.* 28, pp. 38, pls. 15).—This bulletin urges the culture of better varieties of mangoes in Porto Rico, more particularly in the drier parts of the island on the southern side. Mangoes are now grown in Porto Rico to a considerable extent, but it is claimed that all the varieties are of an inferior quality. Such varieties as are now grown there are briefly described, as well as 8 improved varieties which it is believed might be successfully introduced. Notes are given on the botany of the mango, its cultural requirements, methods of propagation, and cultivation. The uses of mangoes as a desert fruit and for canning, and in the production of marmalade, jelly, chutney, dyes, etc., are also noted, and some suggestions given regarding packing and shipping mangoes and the possibility of developing markets for the fruit in the United States.

The kumquats, H. H. HUME (*Florida Sta. Bul.* 65, pp. 555-566, pls. 2).—A brief history is given of these fruits, with an account of their culture in Florida and analyses of the ash of 2 varieties. According to the author, kumquats were introduced into England from China in 1846 and soon after reached America. The first trees in Florida were planted in 1885. The proper name of the kumquat is *Citrus japonica*. The kumquat is a much-branched shrub 8 to 12 ft. high, with rather close, compact branches. The flowers are sweet-scented like those of the orange, and the fruit round or oblong 1 to 1½ in. in diameter. The juice of the fruit is acid, the rind has an agreeable spicy taste, while the inner portion of it is decidedly sweet.

Of the 2 varieties grown in Florida the Nagami is considered the more desirable, although there is some difference of opinion on this point. It is not as hardy, however, as the variety Marumi. Some measurements are given of the heights attained by these trees at Clearwater, Fla. These varied from 8 ft. 8 in. with the Marumi variety to 10 ft. 9 in. with the Nagami variety. The latter was 10 ft. 8 in. across the head.

As a stock on which to grow kumquats the author recommends *Citrus trifoliatus* for northern Florida and sour orange or pomelo for the southern portion of the State. Rough lemon has been successfully used on soils not too wet. When kumquat buds have been inserted in sprouts from rough lemon roots, which already support and feed a sweet or mandarin orange top, a perfectly healthy union has been secured.

The kumquat is considered harder than most citrus fruits, withstanding almost or quite as much cold as the Satsuma. It is recommended for planting in northern Florida. The trees should be set 8 to 12 ft. apart each way or in rows about 12 ft. apart and the trees 5 ft. apart in the row. The kumquat is considered an especially useful

ornamental, and may be easily grown as a pot plant by budding on *Trifoliata* stock.

The fruit may be picked and packed for market either with or without leaves. It is usually sold in quart boxes. The average percentages of fertilizing ingredients in kumquats were found to be as follows: Phosphoric acid, 0.0529; potash, 0.2709; nitrogen, 0.136.

Winter treatment of orchards and remarks on cultivation, F. W. FACROT and J. T. STINSON (*Missouri Fruit Sta. Bul.* 4, pp. 15, pls. 6).—Popular directions are given for the treatment of orchards in winter for the control of insect pests and fungus diseases, and of the best methods of summer cultivation of orchards in Missouri. The Whippoorwill variety of cowpea is regarded as the most suitable variety for sowing in the orchards as a catch crop.

Catalogue of fruits growing on the experimental grounds (*Iowa Sta. Spec. Bul.*, Feb., 1903, pp. 31, fig. 1).—Lists are given of the varieties of apples, cherries, pears, peaches, plums, grapes, strawberries, junberries, gooseberries, currants, asberries, dewberries, and blackberries growing at the station.

Report of the fruit expert, W. J. ALLEN (*Agr. Gaz. New South Wales*, 13 (1903), No. 5, pp. 506-538).—Notes are given on the experimental fruit orchards at Bathurst, Wagga, Hawkesbury Agricultural College, Pera Bore, Moree, and Wollongbar. The following fruits have been grown in the different orchards, descriptions being given in some instances and data on productiveness: Apples, almonds, apricots, cherries, citrus fruits, figs, filberts, grapes, loquats, medlars, mulberries, mangoes, nectarines, olives, peaches, pears, persimmons, plums, prunes, quinces, and walnuts.

Horticulture in Norway, 1660-1814, S. SKAPPEL (*Tidsskr. Norske Landbr.*, 9 (1903), No. 7, pp. 321-329).

Fruit and vegetable storage and shipment experiments of the U. S. Department of Agriculture, W. A. TAYLOR (*Virginia State Hort. Soc. Rpt.* 1902, pp. 17-29).—An abstract of an address made by the author before the Virginia State Horticultural Society, in which the results secured in the shipment of Bartlett and Kieffer pears, late peaches, and sweet potatoes to the English market are summarized. The results obtained with eastern grown Bartlett pears indicate that they can be landed in London in excellent condition if proper care is taken in picking, packing, handling, and refrigerating them. Small packages, such as the box and half box, are believed to be most desirable. The fruit should be wrapped. In the case of standard grade fruit wrapping increased the net value of the product in boxes 82 per cent and in the case of select grade fruit in boxes 92 per cent. The chief obstacle to the success of the development of a trade with English markets for this fruit is believed to be the large size of the steamship compartments now available. The smallest of these compartments now has a capacity of about 3 carloads. The barrel proved a satisfactory package for Kieffer pears. Wrapped and unwrapped fruit of this variety sold for exactly the same price. This class of pears is used for dessert purposes, and the outlook appears to be favorable for export shipments of this pear in common stowage in moderate quantities.

The late peaches shipped were of the Bilyen variety and netted from \$3.51 to \$3.75 per 6-basket carrier. Sweet potatoes were shipped in barrels fresh from the field and partially kiln-dried, both with and without wrappers. The fresh dug potatoes arrived in better condition than those which had been kiln-dried. The returns as far as received indicated a net value per barrel at New York of \$4.04. The success of these shipments clearly indicates that sweet potatoes fresh from the field can be delivered in London in sound condition with the present facilities for shipping. The trade for these has not yet been developed in London and is still limited.

Cold storage investigations by the U. S. Department of Agriculture, G. H. POWELL (*Trans. Illinois Hort. Soc.*, n. ser., 36 (1902), pp. 363-368; *Amer. Agr.*, 71 (1903), Nos. 9, p. 23; 11, p. 298).—The author gives a brief summary of the results thus far secured in the cold-storage experiments being conducted by the U. S. Depart-

ment of Agriculture. In a comparison of the keeping quality of apples picked when nearly grown and still undercolored, with larger, more highly colored but firm fruit picked 2 weeks later, it was found that the more mature apples kept just as long, were as durable on removal, were superior in quality, and worth more than the fruit picked while still immature. The most striking differences between these 2 grades of fruits were shown in their relative susceptibility to apple scald, the immature fruits being much more susceptible to this trouble than the more mature fruits. As a prevention of scald it is recommended that only well-developed, highly colored fruit be stored and that this be placed as soon as picked in a temperature not above 32° F. and removed from storage before the scald begins.

Like results were obtained with Kieffer pears picked at different degrees of ripeness, the more mature fruit keeping fully as well as the greener fruit if placed quickly after picking in a temperature not above 32°. The best results with peaches were obtained when the fruit was fully developed and highly colored but still hard when it entered the storage room. Peaches in any way soft were found to break down quickly on removal, while greener fruit was inclined to shrivel.

Delay in storage after the fruit was picked injured its keeping quality. When Bartlett pears were delayed from 2 to 4 days before being stored they ripened within 2 or 3 weeks, while fruit stored immediately after picking was finer at the end of 5 weeks. Kieffer pears stored immediately in a low temperature kept in prime condition until April. When storage was delayed 10 days they showed softening and discoloration at the core in about 30 days. Delay in the storage of apples, more particularly the long-keeping sorts, was not found to be so serious as with the other fruits; nevertheless much delay in storage does not in any wise improve the keeping quality, and whenever the climatic or other conditions are such as to hasten the ripening of the fruit delay in storage is harmful. The author considers it much better to leave the fruit on the tree until it can be put in cold storage, rather than to pick and store it in the orchard or in cars.

Relative to the temperatures at which the various fruits keep best it was found that 32° was better for both apples and pears than any temperature higher than this. Kieffer pears, for instance, stored in a temperature of 32° kept until April, while at 36° they reached their commercial limit in December. Peaches also kept better at a temperature of 32° than at any temperature higher than this, and the quality of the fruit was equally as good. The ability of all the different fruits to stand up when removed from a temperature of 32° was far greater than from any temperature higher than this. The general impression that cold-storage fruits lack quality and deteriorate quickly when removed from cold storage has been found to be fallacious.

Wrapping fruit in tissue, parchment, paraffin, or newspaper has been found to prolong the storage season of winter apples and late-keeping pears, preserving their fresh appearance, preventing accumulation of mold on the stem or at the calyx, lessening the decay, and preventing evaporation from the fruit. Little difference was noticeable in the efficiency of the different wrappers. It is believed that with all fancy fruit for long keeping wrapping is worthy of commercial consideration.

As to the effect of different kinds of packages on the keeping quality of fruit it was found that the smaller open packages, which permit of ventilation and rapid cooling down, are better than larger packages like barrels, in which the fruit in the center is likely to maintain a considerably higher temperature than the outside fruit, and thus undergo a ripening process which hastens decay.

Cold storage of fruit, J. B. REYNOLDS and H. L. HURT (*Ontario Agr. Col. and Expt. Farm. Bul. 123*, pp. 8).—The details are here given of a number of experiments, the summarized results of which have been noted from another source. (E. S. R., 14, p. 760.)

Commercial fruit evaporators, J. C. WHITTEN and L. A. GOODMAN (*Missouri Sta. Circ. of Information 14*, pp. 8, figs. 5).—This circular discusses the desirability of

a cheap commercial fruit evaporator for the apple regions of Missouri, and gives a detailed plan of such an evaporator. It is stated that the revenue derived from the evaporated cores and peelings alone is often sufficient to pay for evaporating the whole crop.

A modern efficient and economical evaporator for apples and peaches consists essentially of a plain frame building made of well-battened boxing with a slatted upper floor about 6 ft. from the ground for the fruit, and a big box stove heated with wood on the lower floor. The upper floor should be made of slats 1 in. square and beveled to prevent the fruit from clogging. These are spaced $\frac{3}{8}$ to $\frac{1}{2}$ in. apart to allow the hot air to pass up through the fruit, which is spread on this floor. One or two ventilators in the ridge of the roof will be necessary to carry off the moist hot air. A drying room 12 by 12 ft. or 16 by 16 ft. is believed to be large enough for most farmers or fruit men. Fruit bins and paring tables are arranged in a lean-to shed against the main building.

After paring and slicing the fruit is dropped into galvanized wire trays 3 by 3 ft. and at once placed in the bleaching house. Only a few minutes are required to bleach the fruit, after which it should be carried immediately to the drying room and emptied on the floor. In the bleaching house the fruit is subject to the fumes of sulphur until the bruised and discolored parts are pure white. Should it be left in the bleacher too long the quality is injuriously affected, but "when properly bleached none of the fruit flavor or quality is lost, which is always the case when bleaching is done after evaporation." The fruit from the bleacher is placed on the drying floor 4 to 6 in. deep and frequently stirred with a shovel. The deeper the fruit is on the floor the more stirring will be required.

When the evaporator is not being used for the fruit itself it may be used for evaporating the skins and cores. Afterwards, however, everything must be washed clean before using for fruit again. On this account it is recommended that a portion of the drying room be kept exclusively for the drying of skins and cores.

A detailed estimate is given of the building material required for an evaporator 40 by 40 ft., with the necessary paring shed.

Directions for picking, storing, and uses of fruit, C. MATTHIESEN (*Anvisning til nedplukning, opbevaring og anvendelse af frugt*. Copenhagen, 1902, pp. 96).—A prize essay, published by the Royal Agricultural Society of Denmark.—F. W. WOLL.

Science and experiment as applied to canning, O. L. DEMING (*Chicago: Sprague Canning Machinery Co., 1902, pp. 172, figs. 48*).—This book is composed largely of a collection of papers which has appeared at various times in the *Canner and Dried Fruit Packer*. It deals with the historical development of the canning industry in this country, the bacteriology of canning, particularly as applied to corn and peas, and the process of packing corn and peas. Papers bearing on the insects affecting these crops are included. The papers dealing with the bacteriology of canning are by S. C. Prescott and W. L. Underwood.

Maine canning industry, B. M. FERNALD (*Portland, Me.: Marks Printing House, 1902, pp. 1-8*).—A popular address delivered before the State Board of Trade at Bangor, Me., March 25, 1902, on the history and development of the canning industry in Maine.

Culture of coffee; fertilizer experiments, G. D'UTRA and R. BOLLIGER (*Bol. Agr. São Paulo, 3. ser., 1902, Nos. 2, pp. 71-83; 6, pp. 365-369*).

Cacao (*Agr. News [Barbados], 2 (1903), No. 23, p. 69*).—A statement is given of the comparative yields of cacao on plats of various sizes in Grenada, and of the yields obtained on plats in different localities fertilized with a number of different fertilizers.

Experiments in manuring strawberries, E. MARRE (*Prog. Agr. et Vit. (Ed. L'Est), 24 (1903), No. 3, pp. 88, 89*).—A study was made of the value of sulphate of potash in growing strawberries. The average yields on the control plat for 2 years were 11,600 kg.; on the plat fertilized with 200 kg. of nitrate of soda and 50 kg. of

superphosphate the yield was 17,900 kg.; and on the plat fertilized with this same amount of nitrate of soda and superphosphate with 200 kg. of sulphate of potash in addition the yield was 19,700 kg. The soil on which the experiment was conducted was fairly rich and the strawberries well cultivated. The yields indicate nearly a 50 per cent increase from the use of a complete fertilizer over the control plat.

Note on the chemical composition of wood strawberry (*Fragaria vesca*), G. PARIS (*Chem. Ztg.*, 26 (1902), pp. 248, 249; *abs. in Ztschr. Untersuch. Natur. u. Genussmit.*, 6 (1903), No. 1, pp. 29, 30).—Analyses are reported of 3 samples of juice from unripe Italian wood strawberries.

The grape in Kansas, W. H. BARNES (*Topeka: Kansas State Hort. Soc.*, 1901, pp. 139, pl. 1, figs. 6).—This contains compiled information on how to plant, grow, and market grapes in Kansas, including descriptions of varieties, extracts from bulletins, reports from grape growers, etc.

The application of chemical fertilizers in the culture of grapes on the calcareous soils of Charente, J. M. GUILLON and G. GOURAND (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 23, pp. 1076-1078; *Jour. Agr. Prat.*, n. ser., 4 (1902), No. 52, pp. 831-833).—Experiments have been in progress for 5 years to determine the relative effects of different commercial fertilizers alone and in various combinations for grapes on the calcareous soils of Charente. The yields obtained are tabulated. The data indicate that for the first 2 years there was practically no effect from the use of the different fertilizers. After that the heaviest yields were obtained with potash fertilizers. Phosphatic fertilizers stood next and nitrogenous fertilizers last. Barnyard manure produced excellent results in every case, fully equal to those given by commercial fertilizers. Analyses are given of the soils on which the experiments were conducted, but they do not indicate in any manner what fertilizer is most needed. It is pointed out that only experiments extending over several years can determine this.

Experiments with Trifoliata in Texas, H. M. STRINGFELLOW (*Pacific Fruit World*, 14 (1903), No. 18 [19?], p. 6).—Satsuma oranges grafted on Trifoliata stock withstood a temperature of 16° F., but were killed to the ground another season when the temperature fell to 8° F. They came out at the surface of the ground again, however, and made a fine growth, bearing a few oranges the second season. Fifty trees of Trifoliata top-budded with Satsuma were unable to withstand a temperature of 2° F. Not only the tops but the trunk down to within 6 in. of the ground was killed. Some of the seed of the Satsuma oranges, grown on Trifoliata stock, were planted and the resulting trees occasionally showed plainly marked Trifoliata leaves, thus indicating the production of a graft hybrid.

The effect of winter freezes on grapes, A. BONNET (*Prog. Agr. et Vit. (Éd. L'Est)*, 24 (1903), No. 5, pp. 137-142, pl. 1, fig. 1).—A discussion, with drawings, showing the effect of winter freezing on grapevines and the appearance of the dead and the healthy wood.

Grafting green grapevines, J. ZAWODNY (*Gartenflora*, 51 (1902), No. 16, pp. 429, 430, figs. 6).—This has been very successfully practiced by the author in May, June, and the beginning of July, when the stock is growing luxuriantly. The graft is made obliquely through a node. The details of the method are brought out in a series of drawings.

The rooting of berlandieri solved, E. JACHET (*Rev. Vit.*, 18 (1902), No. 466, pp. 582-584).—The species of grapes *Vitis berlandieri* has been found especially valuable in reestablishing the French vineyards on soft limestone soils. The chief objection to it has been the great difficulty of rooting it according to the usual methods of rooting grapes. The author found that by ringing the yearly shoots of the vines just below a bud a callus was produced and the bud considerably enlarged. During the winter the shoots were cut just below the bud and planted out in the nursery as cut-

tings. About 80 per cent of the cuttings thus made have been successful, producing strong plants where by other methods scarce 5 per cent were successful.

The ringing or annular incision of vines, A. J. PERKINS (*Jour. Agr. and Ind., South Australia, 6* (1903), No. 6, pp. 402-405).—The author states that the practice of ringing grapes has lately come into extensive practice among South Australian Zante currant growers. Observations thus far indicate that there has been an increase of fruit yield from this practice. The author presents the data obtained in some ringing experiments with some badly setting Gordos in the Roseworthy College vineyard. In one experiment the plat consisted of low gooseberry bush vines gnarled and irregular in stem and habit of growth. It was difficult to ring these vines satisfactorily, but on 154 ringed vines there was 51.22 per cent of well-set bunches and practically no well-set bunches on vines not ringed. Thirty-one vines were "topped" and on these there was 16.24 per cent of well-set bunches. In another plat consisting also of gooseberry bush vines, but with taller and more regular stems, 22 ringed vines bore 78.59 per cent of well-set bunches, while 2 unringed vines bore but 4.35 per cent of well-set bunches. On a third plat, where the Gordos were trained on a spur-pruned cordon with stems 3 ft. high, 37 ringed vines contained 72.84 per cent of well-set bunches, while 1 vine not ringed contained but 23.08 per cent of well-set bunches.

New investigations on the resistance to phylloxera, L. RAVAZ (*Nouvelles recherches sur la résistance au phylloxera. Montpellier: Coulet & Sons, 1903, pp. 20, pls. 2*).—The resistance of a large number of species and hybrids of grapes to the phylloxera has been determined by growing the plants in benches of sand to which the phylloxera had been added.

Potency of the pollen of self-sterile grapes, S. A. BEACH (*New York State Sta. Bul. 223, pp. 269-282*).—The problem as to whether or not pollen from self-sterile or imperfectly self-fertile varieties of grapes is capable of fertilizing self-fertile grapes has been investigated and the data obtained are recorded in the present bulletin. Pollen from the varieties Black Eagle, Brighton, Eldorado, Herbert, Lindley, Merri-mack, and Salem, all of which in previous tests at the station had proved self-sterile or very nearly so, was used to pollinate the following 5 strongly self-fertile varieties: Concord, Delaware, Diamond, Niagara, and Worden, and also the variety Vergennes, often less strongly self-fertile than the above. More carefully conducted cross pollinations were also made between the self-sterile varieties Hexamer and Black Eagle, the nearly self-sterile variety Ozark, and the strongly self-fertile varieties Hopkins and Bailey, using the last 2 varieties as mothers.

The number of clusters and pistils cross pollinated in each instance with each variety, the number of fruits developed, size of seeds contained, etc., in all these experiments are recorded in tables. The results obtained, considered in connection with previous work at the station, indicate that self-sterile varieties are practically incapable of fertilizing either other self-sterile varieties or self-fertile varieties. In some instances, however, the pollen is not altogether impotent, and a few scattering fruits result. "The questions, however, are still not satisfactorily answered as to whether the self-sterility under investigation arises because the pollen is uncongenial to its own pistil, or because it is deficient in amount, or because it is nearly or quite impotent either upon its own or upon other pistils. The last-named condition seems to hold with Black Eagle pollen."

Influence on self-fertility of girdling or bending the canes, S. A. BEACH (*New York State Sta. Bul. 223, pp. 269, 270, 282-290, pls. 2*).—Experiments have been made to test the effect on the self-fertility of grapes of girdling or bending the fruiting canes. Work was done after the leaves began to appear, but about 3 weeks before the blossoms opened. Some of the canes were ringed just beyond the first node, a piece of bark $\frac{1}{2}$ to $\frac{1}{4}$ in. wide being removed. Other canes were either tied to lie horizontally upon the trellis for about $\frac{1}{4}$ their length, then bent sharply, following

the next wire in the opposite direction, or were twisted as tightly as possible without breaking twice around the wire for about $\frac{1}{4}$ of their length. The data obtained with 10 varieties treated by the different methods are tabulated and discussed.

With Hercules, a self-sterile variety, left open to cross pollination, 29 clusters developed on the girdled canes and but 16 on the untreated canes. There was also an apparent advantage with the varieties Vergennes, Brighton, and Eldorado from girdling and bending. "The treatment of the self-sterile Herbert and Salem failed to cause them to fruit. The self-fertile varieties Concord, Delaware, Empire State, and Niagara have generally a higher average rating on girdled than on untreated canes, but the advantage of the treatment, if any, is not striking. If the girdling can be used on such nearly self-sterile varieties as Brighton and Eldorado, or such imperfectly self-fertile kinds as Vergennes, when these varieties stand in proximity to strongly self-fertile kinds and are exposed to cross pollination from them throughout the blooming season, it may be that their productiveness may be thus profitably increased. Further investigations should be made on this point, as well as a comparative study of early and late girdling."

A study of grape pollen, N. O. BOOTH (*New York State Sta. Bul.* 224, pp. 291-302, pls. 6, fig. 1).—An abstract of this work has been made from another source (E. S. R., 14, p. 762).

Spanish almonds and their introduction into America, D. G. FAIRCCHILD (*U. S. Dept. Agr., Bureau of Plant Industry Bul.* 26, pp. 14, pls. 8).—A brief account of the almond industry of Spain, with descriptions of the chief varieties grown, including the famous Jordan type. This nut brings 8 to 10 cts. more per pound on the English and American markets than any other variety, it being especially desired by confectioners for the manufacture of the best quality of salted and sugar-coated almonds. The Jordan almond was introduced into California by John Rock, in 1897, 3 trees of which have borne true Jordan almonds.

The author secured scions of the true Jordan almond in Spain for this Department, which are now being successfully grown in different places in the United States. In the author's opinion, the chief difficulty to the successful culture of the Jordan almond in this country will be to find localities suitable for its growth which are not subject to late frosts.

Plant propagation; some phases of practical horticulture adapted to use in the public schools, W. L. HOWARD (*Missouri Sta. Cir. of Information* 13, pp. 50, figs. 20).—This gives popular directions for the propagation of plants by seeds, cuttings, layering, grafting, and budding. It is intended more particularly for use in the school room and deals with all the more common house plants, orchard fruits, etc.

Outline of greenhouse laboratory work, S. B. GREEN and R. S. MACKINTOSH (*Minnesota Sta. Class Bul.* 12, pp. 72, figs. 58).—This bulletin has been prepared as a guide for the use of students taking greenhouse laboratory work in winter at the Minnesota School of Agriculture. It is made up of an outline series of exercises designed to illustrate the principles underlying such matters as seed testing and sowing, use of mineral fertilizers, pollination of flowers, growing plants from cuttings, grafting, potting, transplanting, preparation of spraying mixtures, packing and handling nursery stock, uses of certain garden tools, pruning, etc.

Distribution of seeds and plants, E. J. WICKSON (*California Sta. Seed Bul.*, 1903-8, pp. 8).—The usual annual announcement of the seeds and plants available for distribution within the State, with notes in some cases on the growth of the plants at the station. Among the more important plants mentioned which have been grown at the station are a variety of oats from the Seed Breeding Institute of Svalöf, Sweden, Hanna barley, large melilot, *Lippia nodiflora*, edible oxalis (*Oxalis crenata*), Chinese yam, several varieties of port, sherry, and table grapes, etc.

Tropical plants of commercial importance, F. DE WILDEMAN (*Les plantes tropicales de grande culture*. Brussels: Alfred Castaigne, 1902, pp. IV+304, pls. 38, figs. 51,

map 1).—This work contains considerable information on the botany, statistics, preparation, and in some instances on the composition of coffee, cacao, vanilla, cola, and rubber-producing plants of tropical Africa. A bibliography of the literature of plant distribution in central Africa is included in the opening chapters.

Studies on some essences of the French colonies, E. CHARABOT (*Agr. Prat. Pays Chauds*, 2 (1903), No. 10, pp. 395-399).—A study was made of the essential oils obtained from *Ocimum canum*, *Clausena wilsonii*, and a species of wild mint. The essential oil obtained from *Ocimum canum* had a yellowish color and under the influence of cold produced crystals which corresponded to the formula $C_{10}H_{16}O$. The odor resembled that of camphor.

Forcing lilacs, J. VILLEBENOIST (*Rev. Hort. [Paris]*, 75 (1903), No. 4, p. 91).—Lilacs were placed November 15 in a dark room, surrounded by blocks of ice to the height of 1.2 to 1.5 meters. This kept the temperature of the room at 1 to 2° C. The plants were removed December 3 to the forcing house and at the same time 20 other plants that had not been thus treated were placed in the forcing house for comparison. Blossoms were cut from the plants that had been surrounded with ice beginning with December 21, while the first flowers from untreated lilacs were obtained December 29, 8 days later.

Ether and chloroform in forcing (*Amer. Gard.*, 24 (1903), No. 429, pp. 165, 166).—A summarized account of present methods of using ether and chloroform in forcing plants into early bloom.

Roses for English gardens, GERTRUDE JEKYLL and E. MAWLEY (*London: Country Life*, 1902, pp. XVI+166, pls. 191).—This work describes present as well as older varieties of English roses, and contains many chapters on the uses of roses in arbors, hedges, training on pillars and walls, etc. The second part of the work deals with the details of planting, pruning, and propagating roses, exhibiting roses, growing under glass, etc. The book is profusely illustrated. Lists are given in the final chapter of the best roses for various uses.

Gardens old and new—The country house and its garden environment (*London: Country Life; New York: Charles Scribner's Sons* [1902], pp. XLVI+284, figs. 390).—This volume, edited by J. Leyland, is similar in character and scope to volume 1 (*E. S. R.*, 13, p. 653). The different types of English gardens—chiefly those of a formal nature—are profusely illustrated and sufficient text given to explain their historical setting and architectural features.

FORESTRY.

Relation of forestry to public health, W. H. BREWER (*Forestry and Irrig.*, 9 (1903), No. 1, pp. 12-15).—A report is given by the chairman of the committee appointed to investigate the subject of the relation of forestry to public health for the American Public Health Association. The report discusses the physical factors involved in the relation of forests to health, which are the forest water, soils, forest air, and climate. These are all held to be more or less closely related and all enter into the hygienic relations of forests.

Relation of forestry to the farmer, H. C. PRICE (*Jour. Columbus Hort. Soc.*, 17 (1902), No. 3, pp. 96-100).—The value of the farmer's wood lot is pointed out and the relative merits of different kinds of trees for planting are shown. For posts and other uses requiring durability when exposed to the ground the author recommends the planting of black locust, catalpa, chestnut, European larch, and various oaks, while for sawed timber he recommends cottonwood, ash, and white pine among the more rapid-growing trees, and black walnut, cherry, and others for slower growth.

Outlook of the timber supply in the United States, B. E. FERNOW (*Forestry Quart.*, 1 (1903), No. 2, pp. 41-49).—In a paper on this subject, the author reviews the timber supply and production of the United States. The consumption of dif-

ferent kinds of wood is shown in tabular form, from which it appears that 26,153,000,000 ft. B. M. of coniferous timber and 34,786,000,000 ft. B. M. of hard woods were consumed during the year covered by the Twelfth Census. Of the individual species white pine leads the list, although the southern pines exceed the northern representative in the quantity produced. In addition to the figures above given there must be added at least 1,000,000,000 ft. for wood pulp and 300,000,000 ft. for timber cut on farms.

New forest reserves (*Forestry and Irrig.*, 9 (1903), No. 1, p. 3).—A new forest reserve known as the Absaroka Forest Reserve, located in the southern part of Montana, has been recently set aside by Presidential proclamation. It embraces an area of 1,311,600 acres and a portion of it bounds the Yellowstone National Park on the north. There have also been recently created in the Hawaiian Islands forest reserves amounting to approximately 250,000 acres.

Natural reproduction in the Adirondack forests, A. KNECHTEL (*Forestry Quart.*, 1 (1903), No. 2, pp. 50-55).—The results of a study made in the Adirondack forests on the natural reproduction of various species are given. The peculiarities required for seedling production of different trees are described, and it is stated that for the regeneration of white pine, spruce, and hemlock a good mineral seed bed is required. In virgin forests these species reproduce themselves principally on rotting logs and are found but rarely on the forest floor. Balsam and cedar reproduce themselves abundantly where the light conditions are adequate, and hard woods are readily reproduced everywhere. A brief account is given of an attempt at planting coniferous trees in the Adirondacks. About half a million trees were planted on over 700 acres of land at a total cost of about \$2,500.

The forests of Maine, E. E. RING (*Forestry and Irrig.*, 9 (1903), No. 1, pp. 8-10).—A summary is given of the report of the State forest commissioner, in which an attempt is made to estimate the standing timber within the State, particular attention being given the merchantable spruce. In making this estimate the work was divided according to the watersheds. The results of explorations show that there are standing in Maine at the present time 21,239,000,000 ft. of spruce, besides large quantities of pine, cedar, hemlock, poplar, and various species of hard woods. It is estimated that the annual increment of the Maine forests is sufficient to admit of cutting 637,000,000 ft. of spruce timber yearly without depleting the supply. The present capacity of the pulp mills is about 275,000,000 ft., leaving for sawmill purposes 360,000,000 ft. if the annual increase alone is cut. The different water systems of the State and their timber supplies are briefly reviewed.

Annual report of the forest administration in South Australia, W. GILL (*South Australia Woods and Forests Dept., Rpt. State Forest Admin., 1901-2, pp. 12, pls. 3*).—The forest reserve area in South Australia is said to slightly exceed 200,000 acres, and planting operations are being conducted on inclosed lands amounting to about 13,500 acres. A general account is given of the year's plantings in which it is shown that 81 per cent of the planted trees are reported as living. The relative merits of *Pinus insignis* and *P. maritima* when grown in artificial plantations are shown by the results obtained in cutting trees of each variety which were approximately 20 years of age. Notes are also given on the cultivation of date palm, and appendices showing the kinds of trees planted and receipts and disbursements of the revenue department of forests.

Report on the forest administration of the Central Provinces, 1900-1901, A. SMYTHIES and J. A. MCKEE (*Forest Dept., Central Provinces, India, Rpt. 1900-1901, pp. 112*).—Detailed reports are given of the Northern and Southern Forest Circles of the Central Provinces of India. The forest area reported upon embraces a little over 19,000 square miles, and the system of management is described at length. Working plans and the various returns of exploitation are given.

Progress report of forest administration in the Lower Provinces of Bengal,

1900-1901, A. E. WILD (*Forest Dept., Bengal, India, Rpt. 1900-1901, pp. 65*).—The reserved, protected, and unclassified forest areas of Bengal amount to 13,589 square miles, or 8.67 per cent of the total area, a little more than three-fifths of which is under protection. A detailed account of the management of the state forests is given. Studies on the rate of growth have been continued and preliminary working plans prepared for a number of tracts. The report on fire protection shows 53,278 acres burned over, about half of which were situated within the fire protection areas. Detailed reports are given of plantings, thinnings, grazing, and other exploitations. The total output of timber and fuel during the time covered by the report was 41,093,239 cu. ft.

A hardy American forest tree, J. P. BROWN (*Arboriculture, 2 (1903), No. 1, pp. 95-128, figs. 30*).—An account is given of the value of *Catalpa speciosa* as an American forest tree, the article being a revised and expanded edition of a pamphlet published in 1898 by the author relating to the hardy catalpa. Descriptions are given of this tree, its habitat, habits of growth, its value for various construction purposes, analysis of the wood, and methods of managing plantations, a number of successful plantations being described at considerable length. In conclusion the author states as the result of his 30 years' study of this tree that one of the prime necessities is the securing of true seed of this species. There are many hybrids between this and inferior species which have little or no value as forest trees. The tree naturally succeeds best on rich soils, and according to the author plantings should not be nearer than 8 by 8 ft. The roots of the tree, it is said, will in 3 years cover 16 sq. ft. and where planted too closely they will interfere and result in a dwarfed, stunted growth. The hardy catalpa is said to be less subject to disease than many other trees and has few destructive insect enemies. When planted in exposed regions the author suggests the planting of wind-breaks, but under no circumstances should such trees as the osage orange, cottonwood, or mulberry (except the Russian mulberry) be planted with the catalpa as a wind-break. In these conclusions the author differs somewhat from a recent publication of the Bureau of Forestry of this Department (E. S. R., 14, p. 574). See also Forestry Bulletin No. 37.

The Norway spruce in Iowa, L. H. PAMMEL (*Forestry and Irrig., 9 (1903), No. 1, pp. 34, 35*).—According to the author the success which has followed the planting of the Norway spruce in many of the Eastern States led to its extensive planting in Iowa in all kinds of soils under varying conditions, with the result that more than half the trees have proved failures. The writer has observed a few localities in which the trees are in a healthy, vigorous condition, but generally speaking the species is considered a failure and should not be used for commercial or ornamental plantings. The white spruce (*Picea alba*) and blue spruce (*P. parryana*) are both to be preferred above the Norway spruce for planting in that State. A tabular statement is given showing the height and diameter of a number of trees ranging from 21 to 35 years of age.

Trees for shade, ornament, and roadside planting, W. R. LAZENBY (*Jour. Columbus Hort. Soc., 17 (1902), No. 3, pp. 93-95*).—A brief account is given of the relative merits of different kinds of trees for shade, ornamental, and other planting, and a list is given of trees for street planting which are adapted to that purpose in the region covered by the report. The best species for this purpose are the various ashes, maples, beech, oak, chestnut, linden, sycamore, poplars, and honey locust, with some of the smaller growing trees, as buckeye, ironwood, hardy catalpa, etc., for narrow streets.

How to grow a forest from seed, F. W. RANE (*New Hampshire Sta. Bul. 95, pp. 95-107, figs. 11*).—Directions are given for forest seed collection, propagation, etc., in which the principal illustrations are of experiments with the white pine. The methods of collection and preservation of seed are described at considerable length and directions given for the preparation of seed beds, the kind of soil necessary, the subsequent planting, cultivation, etc., to the harvesting of the crop.

Collecting jack-pine seed, E. A. STERLING (*Forestry and Irrig.*, 9 (1903), No. 1, pp. 27-32, figs. 5).—On account of the planting experiments which are to be undertaken in the new forest reserves in western Nebraska, the Bureau of Forestry has been making efforts to collect in considerable quantities the seeds of a number of trees. Among several species which give promise of success is the jack pine of our northern forests (*Pinus dicaricata*). The methods followed for collecting this seed are described at considerable length. The cones are collected and subjected for some time to artificial temperatures ranging as high as 150° F. in order to cause them to open sufficiently to admit of the escape of the seed.

A new method of turpentine orcharding, G. PINCHOT (*U. S. Dept. Agr., Bureau of Forestry Circ.* 24, pp. 8, figs. 3).—A description is given of a new method of working turpentine orchards, which is intended to replace the wasteful and injurious system of boxing. By the method described it is stated that at least 23 per cent more turpentine can be obtained, and the yield is of a higher grade. The cost of the new equipment can be readily paid for in the extra returns of the first season. There is no box cutting under the new system, and consequently little permanent damage is done the trees. It is estimated that by the adoption of this new method at least \$13,000,000 per annum can be saved to the naval-stores industry of the South. The new system, which consists essentially of an earthen cup to catch the turpentine and 2 thin galvanized sheet-iron gutters to convey the resin to the cup, is described, and directions are given for installing the equipment.

The distribution of plants in forest regions, W. M. MUNSON (*Extr. from Maine Forest Com. Rpt.* 1902, pp. 16).—Notes are given on the various agencies which influence and restrict the distribution of plants, the provisions of the plant itself for distribution, the natural forces outside the plant, and the modifying influences or limitations to distribution being given.

Trees and shrubs as sand binders, K. SAJO (*Prometheus*, 13 (1902), No. 673, pp. 769-773).—An enumeration is given of a large number of species of trees and shrubs which are considered valuable for preventing the drifting of loose sand.

The fixation of shifting sands, J. GIFFORD (*Forestry and Irrig.*, 9 (1903), No. 1, pp. 39-44, figs. 5).—Descriptions are given of numerous experiments which have been made in this and other countries to prevent the sands along seacoasts and other places from being shifted by the winds.

Instruction in forestry in Switzerland, A. K. MYHRVOLD (*Ber. Norges Landbr. Høiskoles Virks.*, 1901-2, pp. 92-105).

SEEDS—WEEDS.

The principles of plant production; the seed, F. B. MUMFORD (*Missouri Sta. Circ. of Information* 15, pp. 38, figs. 11).—This bulletin is one of a series intended to present in a pedagogical form the principles of agriculture and describes the various processes and conditions of germination, the principles of seed selection and seed testing, together with a detailed account of various experiments on the effect of age, size of seed, and chemical and physical agents on the vitality of seed. A brief bibliography is appended.

The effect of alcohol on the germination of some seeds, L. SUKATSCHOFF (*Bot. Centbl., Beihefte*, 12 (1902), p. 137; *abs. in Bot. Centbl.*, 90 (1902), No. 7, p. 186).—According to the author, uninjured seed of *Lupinus mutabilis*, after standing from 1 to 5 days in 90 to 100 per cent alcohol, did not have their germinative ability seriously affected, and peas subjected to similar treatment for 3 days were uninjured. Moldy seed of *L. luteus* and *Lepidium sativum*, after remaining for 37 hours in absolute alcohol, were uninjured so far as their vitality is concerned.

Protein bodies of various oil-bearing seeds, B. GRAM (*Landw. Vers. Stat.*, 57 (1902), No. 3-4, pp. 257-296, pls. 4).—Results of microscopical and chemical studies

of the proteid bodies of castor beans, cocoanuts, Brazil nuts, sesame seed, hemp, flax, rape, sunflower, peanut, cotton seed, phenol, etc., are given.

Some frauds in the seed trade. D. VIDAL (*Prog. Agr. et Vit. (Éd. L'Est)*, 24 (1903), Nos. 8, pp. 244-247; 9, pp. 275-277).—A number of the more common forms of substitution and other fraudulent practices in the seed business are described. Among those mentioned are the substitution of inferior seed for those of high price, the mixing of old seed with a low germinative ability with those of higher value, the presence of sand and other mixtures which may have been added intentionally or otherwise, etc.

Report of the Göteborg and Bohus Seed Control Station for the year ended June 30, 1902. J. E. ALÉN (*Red. Göteborgs och Bohus läns frökontrollanst., 1901-2. Göteborg, 1903, pp. 11*).—A detailed report is given of the investigations pursued in testing 333 lots of seed. The maximum, minimum, and average germinations of the different lots of seed are shown, the principal species being grouped into cereals, forage plants, garden, and tree seed. Notes are also given on the occurrence of weed seed in the different samples examined, the principal species represented being enumerated.

Report of the Seed Control Station, Christiania, 1901. ANNA STEEN (*Aarsber. Offent. Foranstalt. Landbr. Fremme, 1901, pp. 513-517*).

The seeds of rescue grass and chess. F. H. HILLMAN (*U. S. Dept. Agr., Bureau of Plant Industry Bul. 25, pp. 1-4, figs. 3*).—It is stated that the seeds of chess, or cheat, have been offered for sale as rescue grass, and the author has made a study of these and related species of *Bromus* in order to present characters which would readily distinguish the different species. Differences are pointed out between the 2 species *Bromus secalinus* and *B. unioloides*, and the chess is said to more nearly approach the seed of *B. racemosus* than that of the rescue grass, but as *B. racemosus* is almost as undesirable as the chess it should probably not be sown for haying purposes.

The Canada thistle. S. LUND and E. ROSTRUP (*Marktidseken, Cirsium arvense. En Monografi. Copenhagen, 1901, pp. 165, pls. 4, figs. 30; abs. in Bot. Centbl., 90 (1902), No. 25, pp. 691-693*).—The results of a monographic study on the Canada thistle (*Cirsium arvense*) are given. The habits of the plant are described at considerable length, its root characters receiving considerable attention. The seed are said to germinate under favorable conditions every year and, on the other hand, they are able to remain dormant in the soils for a considerable time. The seed are also said to pass through the alimentary canal of animals without having their germinative power affected in any way. The anatomy, morphology, and development of the different parts of the plants are described, and suggestions given for combating this weed. The means advised consist principally in cultivation so as to prevent the development of the rootstocks, as well as preventing the spread of the seed.

DISEASES OF PLANTS.

Potato spraying in 1902. F. C. STEWART, H. J. ERSTACE, and F. A. SIRRINE (*New York State Sta. Bul. 221, pp. 235-263*).—The station has begun a series of experiments to ascertain the effect of spraying upon the yield of potatoes in New York. Arrangements have been made by which the station expects to spray potatoes every year for 10 consecutive years, the plan of the experiment to remain the same throughout. The results obtained will be published each year; and in the present bulletin the first year's undertaking is described and the results shown. The experiments were carried on in 2 localities. At each place Bordeaux mixture was applied on tenth-acre plats, one receiving 3 applications throughout the season, the other being sprayed every 2 weeks, and the third remaining as a check. These experiments were conducted on the station farm at Geneva, as well as on Long Island. At Geneva during the first year's work the rows sprayed 3 times yielded at the rate of

317½ bu. per acre, those sprayed 7 times 342½ bu., while those not sprayed yielded 219 bu. per acre. On Long Island the rows sprayed 3 times yielded at the rate of 295½ bu. per acre, those sprayed 7 times 312½ bu., while those not sprayed yielded 267½ bu. The increase where 7 applications were given was largely due to the prevention of late blight and possibly to protection from flea-beetles.

The effect of spraying on the chemical composition of the tubers was investigated, from which it appears that the sprayed potatoes not only yielded more tubers to the hill and were of larger average size than the unsprayed, but the dry matter of the tubers from the sprayed potatoes was 1.4 per cent in excess of that from the unsprayed. This increase was largely starch and amounted to about 7 per cent of the total starch content.

Shall potato growers spray? F. H. HALL, F. C. STEWART, H. J. EUSTACE, and F. A. SIKKINE (*New York State Sta. Bul. 221, popular ed., pp. 7*).—A popular summary of the above bulletin.

Notes on the bacterial disease of potato, G. BATTANCHON (*Prog. Agr. et Vit. (Ed. L'Est), 24 (1903), No. 3, pp. 77-80*).—Attention is called to the bacterial disease of potatoes which has proved very destructive in parts of France for the last 2 years. Based upon his observations the author suggests the rotation of crops and temporary abandonment of the cultivation of potatoes in badly infested regions. Where the potatoes are grown for feeding purposes, as is commonly done, he suggests the substitution of other crops, such as Jerusalem artichokes and various cereals.

Sugar-cane diseases, J. B. HARRISON (*Rpt. Agr. Work Bot. Gard. [British Guiana], 1896-1901, pp. 133-136*).—A report is given of investigations conducted by the late botanist of the Botanic Gardens of British Guiana on diseases of sugar cane in 1900-1901. At this time a disease resembling that caused by the rind fungus was quite common in various parts of the colony. It was attributed to attacks of *Trichosporaria sacchari*, but subsequent examination of the material showed it was due to the fungus *Diplodia cacaoicola*. Experiments were conducted to ascertain the relative susceptibility of different varieties of cane to attacks of this fungus, and it was found that the Bourbon varieties exhibited marked susceptibility while several others were immune to a considerable degree. As to the effect of fertilizers on this disease, it was observed that as a rule the manured canes were more subject to disease than the others, although if applied in the proper proportion and at the right time, fertilizers greatly stimulate the plant to resist the disease through healthier growth. In 1902 ratoon canes from plant canes, which were severely affected in 1900 and 1901, showed but little, if any, sign of disease.

Contributions from the bacteriological laboratory, New South Wales, R. G. SMITH (*Centbl. Bakt. u. Par., 2. Abt., 9 (1902), No. 21, pp. 805-807*).—A report is given on an investigation of gummosis of sugar cane, in which the author separated the organism and compared the gum produced by it with the cane gum gathered from diseased plants. The organism was readily isolated and is described, the chemical reactions being identical with those produced by the cane gum. On account of the similarity the author believes that the active cause of the gummosis is the organism which has been previously described by Cobb under the name *Bacterium vasculare*. Its reaction toward various media is described, together with its other diagnostic characters.

While investigating the gummosis of the sugar cane, a second organism was discovered to which the name *B. sacchari*, n. sp., is given. This organism is found in healthy as well as diseased canes, and causes the production of a peculiar slime-like excretion. A third organism is described which is found in saccharine exudation from *Eucalyptus Stuartiana*. The various characters found indicated that the bacterium was probably new, and the author has described it as *Bacterium eucalypti*. It

resembles *B. levaniformans* in many of its characteristics, but they are not as yet considered identical.

A form of corn smut, G. MOTTAREALE (*Extr. from Ann. Regia Scuola Superiore Agr. Portici, 2. ser., 4 (1902), No. 2, pls. 2; abs. in Bot. Centbl., 90 (1902), No. 5, pp. 125, 126*).—A description is given of a form of smut caused by *Ustilago reiliana* Zev., which attacks the staminal flowers of the corn. This has been under observation for some time, and descriptions are given of the histological and other changes which are caused by the fungus. These abnormal forms are grouped in 3 categories: First, in which the cells are hypertrophied; second, in which the intercellular spaces are greatly enlarged; and third, where the cells are absorbed by the action of the mycelium. The mycelium of the fungus is said to be furnished with haustoria of variable form. The spore formation is described, as well as other microscopical characters of the organism.

The influence of the time of sowing on the occurrence of loose smut of oats, F. K. RAVN (*Tidsskr. Landbr. Planteavl., 7 (1901), pp. 142-148*).—The results of 3 series of trials corroborate the observations of various experimenters that the time of sowing plays an important part in the appearance of loose smut in oats, and that the amount of smut is small or insignificant in case of an early or very early date of sowing, and increases with later sowings.—F. W. WOLL.

Oat smut and its prevention, C. D. WOODS (*Maine Sta. Bul. 87, pp. 210-212*).—A brief description is given of the oat smut, together with a summary of experiments conducted at the Wisconsin Station for the prevention of this disease. The information is largely compiled from U. S. Dept. Agr. Farmers' Bul. 75 (E. S. R., 10, p. 154) and Wisconsin Sta. Bul. 91 (E. S. R., 13, p. 962).

Uredineous infection experiments in 1902, W. A. KELLERMAN (*Jour. Mycol., 9 (1903), No. 65, pp. 6-13*).—Previously noted (E. S. R., 14, p. 530).

A rice disease, T. KAWAKAMI (*Separate from Bul. Soc. Agron. Sapporo, 2 (1901), pp. 49, pl. 1; abs. in Bot. Centbl., 90 (1902), No. 11, pp. 301, 302*).—The original publication, which is in Japanese, describes a disease of rice known as "imotsi," which has been under observation for some time and which occasions considerable loss. The presence of the disease is first manifest by the occurrence of irregular brownish spots upon the leaves, which gradually increase until finally the whole leaf becomes blackened. The stem beyond the point of infection turns black and the stem frequently breaks at the nodes. The spike of a diseased plant is usually completely sterile. The cause of the disease is attributed to *Piricularia grisea*, which is described at some length. Inoculation experiments have been successfully performed, and the author believes that this fungus is identical with that described as causing the disease of rice in Italy, to which the name *P. oryzae* has been given.

Nematode disease of rice, J. VAN BREDA DE HAAN (*Meded. 'S. Lands Plantentuin, 1902, No. 53, pp. 65; abs. in Bot. Centbl., 90 (1902), No. 8, pp. 209, 210*).—A preliminary report is given of 2 diseases of rice which are due to nematodes, one species of which is attributed to *Tylenchus oryzae* and the second to an undetermined species.

Concerning the relation between some species of Pleospora and Helminthosporium, H. DIEDICKE (*Centbl. Bakt. u. Par., 2. Abt., 9 (1902), No. 9, pp. 317-329, figs. 9*).—In a previous publication Ravn has given an account of some diseases of barley and oats due to species of Helminthosporium (E. S. R., 13, p. 565). In the present paper an account is given of similar diseases on *Bromus asper* and upon *Triticum repens*. The principal study was made to determine the possible identity of these fungi with species of Pleospora. By an extensive series of culture and inoculation experiments the author was able to decide that the Helminthosporiums occurring upon *Bromus asper* and *Triticum repens* are conidial phases of species of Pleospora, but the forms on the different hosts are not identical nor can they be reciprocally transferred. The Pleospora on *Bromus* can not be transferred to barley or oats, while that occurring on *Triticum* will infect those host plants. The species

experimented with are not to be considered as identical with *Helminthosporium gramineum*, *H. teres*, and *H. arenae* of the previously mentioned article. The *Helminthosporium* occurring on *Bromus inermis* is probably identical with that here reported on *B. asper*.

The effect of mineral starvation on the parasitism of *Puccinia dispersa*, H. MARSHALL WARD (*Proc. Roy. Soc. [London]*, 71 (1902), No. 469, pp. 138-151, figs. 4).—In a previous publication (E. S. R., 14, p. 772) the author has shown that *Puccinia dispersa* is specialized to closely related species of *Bromus*. In the present investigation an attempt is made to determine whether the varying infective power of the fungus is due to nutritive conditions of the host plant or whether there is some relation between the mycelium of the fungus and the living contents of the host cells. A series of experiments was carried out in which plants subjected to various condition of nutrition were inoculated with spores of the fungus. The results obtained showed that while the starvation of the plants reduced the size of the host plant and materially diminished the quantity of spores produced by the fungus infecting the plant, it did not affect either the virulence of the spores or the predisposition to infection on the part of the grass. It was further shown in the case of plants which were highly manured that high cultivation does not diminish the predisposition of plants to infection, nor could this treatment be expected to increase resistance or confer immunity upon the host plants. There seems to be evidence of the existence in the cells of the fungus, as well as those of the host plant, of certain enzymes or toxins which are decisive factors in the infection or immunity of the plants, but as yet no such substances have been isolated.

The club root of cabbage, L. MANGIN (*Jour. Agr. Prat., n. ser., 4* (1902), No. 45, pp. 604-606, figs. 5).—A description is given of the club root of cabbage and allied plants caused by *Plasmodiophora brassicae*. It is stated that in transplanting from the seed bed great benefit may be obtained if the roots of plants be dipped into a thin whitewash or milk of lime before permanently setting in the field. This of course will prove beneficial only where the plants have been grown in seed beds which were not infested with the fungus.

Studies on *Plasmodiophora brassicae*, FEINBERG (*Deut. Med. Wchnschr., 28* (1902), No. 3; *abs. in Jour. Roy. Micros. Soc. [London]*, 1902, No. 5, p. 586).—A study was made of the organism causing club root of cabbage and other cruciferous plants in order to ascertain whether it was related to the cause of tumors in the animal kingdom. In sections cut from a diseased cabbage root the author found the cells filled with masses of spores, amoeba-like bodies, and in some cases the plasmodium developing into spores. In examination made of tumors from the human body the author did not find either the characteristic parasites or spores present.

***Bacillus subtilis* and *B. vulgaris* as plant parasites,** C. J. J. VAN HALL (*Centbl. Bakt. u. Par., 2. Abt., 9* (1902), No. 17-18, pp. 642-653).—The frequent presence of these common bacteria in rotting potatoes, parsnips, ruta-bagas, etc., has led to a study of their possible parasitism. The author conducted a series of experiments to test the possibility of producing the rot by pure cultures of these organisms. A large number of plants which form tubers or other fleshy underground parts, as well as many other parts of plants, were the subject of the experiments. It was found that at temperatures from 24 to 30° C. no infection took place when the inoculation material was secured from soil decoctions, although it was quite common on some of the plants when the temperature was from 37 to 42°. *Bacillus subtilis* was found to attack parasitically the tubers of potato and Jerusalem artichoke, as well as the seed of the hazelnut, when inoculated from soil infusions; when from pure cultures, the temperature of the medium was found to influence the susceptibility to infection. At 23° C. potatoes and ruta-bagas were slightly affected; at 30° a number of other plants showed evidences of rot; and at 37° potatoes, artichokes, celery, parsnips, various kinds of beets, ruta-bagas, etc., were badly rotted. In the

experiments with pure cultures of *B. vulgatus* it was found that the organism caused severe rotting of many fleshy roots, tubers, etc., at a temperature of 37°; a slight rotting of potatoes, cauliflower, and horse-radish at 30°; and no infection at 23°. The minimum temperature for *B. vulgatus* seems to be about 30° C. and for *B. subtilis* about 23°. The organisms seem to secrete a toxin, which is injurious to the host plant, and they probably gain entrance to the host through this means. The author claims the parasitism of these organisms is fully established, that they cause rots on many stored crops, and as a precautionary measure the minimum temperature for storage should be below that required for the active parasitism of the bacteria. It is believed that in warmer climates these organisms may cause excessive losses.

Asparagus rust, J. ISAAC (*California Bd. Hort. Rpt. 1901-2*, pp. 81-88, figs. 4).—A description is given of the asparagus rust (*Puccinia asparagi*), and extensive quotations are given from station publications relating to the spread and control of this disease.

A mushroom disease, G. T. MALTHOUSE (*Trans. Edinburgh Field Nat. and Micros. Soc.*, 4 (1901), p. 182; *abs. in Bot. Centbl.*, 90 (1902), No. 8, p. 208).—Mushrooms which are extensively grown in tunnels in Edinburgh and other parts of Scotland have been subject to a serious disease which is caused by some species of *Verticillium*. The presence of the spores of this fungus in the air of the tunnels was demonstrated, and after spraying the walls with 3 applications of corrosive sublimate solution no trace of the spores could be detected either in the air, water, or soil of the tunnel.

Concerning the susceptibility of different varieties of apples to scab and the relation of weather to the same, R. ADERHOLD (*Arb. K. Gesundheitsamte, Biol. Abt.*, 2 (1902), No. 5, pp. 560-566).—The results of 5 years' continuous observation on the varying susceptibility of 160 varieties of apples to apple scab are given. Very marked differences are noted for some varieties for the different seasons, but a few seemed quite resistant throughout the whole period of observation. The relation of the occurrence of apple scab and atmospheric conditions is discussed, and in general it is claimed that the weather during the early part of the summer influences to a great degree the amount of scab occurring on the apple trees in Proskau. A comparatively dry period in May and June was associated with a decided decrease in the proportion of disease, while a wet early summer and an epidemic occurrence of scab seemed to be correlated.

The leaf-curl disease of the peach and its treatment, W. M. SCOTT (*Georgia State Bd. Ent. Bul.*, 6, pp. 12, figs. 3).—A description is given of the leaf curl of peach and other trees, which is said to be confined almost entirely to the northern half of Georgia, occurring rarely in the southern and middle portions and then usually upon young orchards which were planted with nursery stock brought from infested regions. The nature of the disease is described at some length and suggestions given for its prevention. Of the numerous fungicides which have been recommended Bordeaux mixture seems to have given the most satisfactory results, although the lime and sulphur wash which is used in fighting scale insects has proved efficient, particularly if 4 or 5 lbs. of copper sulphate be substituted for part of the salt called for by the regular formula.

Spraying experiments were conducted under the author's direction which showed that Bordeaux mixture applied 2 or 3 weeks before the blooming period would almost absolutely prevent the leaf curl. One application was usually sufficient, but if rain should follow the spraying within a few days a second application would be necessary to secure the best results. If the spraying is delayed until after the buds begin to open only a partial prevention of the disease can be secured. As nursery stock is somewhat subject to the disease the author recommends the dipping of the plants before planting in a barrel containing Bordeaux mixture, care being taken, however, that the roots are not covered with the fungicide.

The pear blight in California, J. ISAAC (*California Bd. Hort. Rpt. 1901-2*, pp.

53-65, fig. 1).—The symptoms of disease, manner of attack, and suggested methods of treatment are given, the investigations of M. B. Waite, of this Department, being referred to. The author states that pear blight in a destructive form is limited to a few counties in the southern part of the State. Its bacterial nature is pointed out and the agency of bees and other insects in spreading the disease is shown. The remedy recommended for suppressing this disease is a vigorous cutting out and destroying of the diseased wood.

Studies on plum blight, L. R. JONES (*Centbl. Bakt. u. Par., 2. Abt., 9 (1902), No. 22-23, pp. 835-841*).—The substance of this paper was presented at the Washington meeting of the American Association for the Advancement of Science (E. S. R., 14, p. 531). The morphological and physiological characters of the pear blight organism (*Bacillus amylovorus*) are described at considerable length. The author concludes that there are 2 strains of the organism which in all essentials behave alike. Inoculations into plum branches were in no case successful, while if inoculated into pear shoots they failed if the pear trees were in a semi-dormant condition. The experiments seem to show conclusively that the plum is much more resistant to the invasion of the bacillus than the pear, and infection is probably possible only when conditions are peculiarly favorable during the spring and early summer.

The root knot of plum, prune, and peach trees, J. ISAAC (*California Bd. Hort. Rpt. 1901-2, pp. 77-80*).—An account is given of the root knot of these stone fruits, in which the main roots usually where they branch from the trunk are more or less severely affected by the appearance of large knots. These, the author says, are sometimes due to fungus growths, while other forms are attributed to mechanical injury. In nursery stock all trees showing the presence of any knots upon their roots should be destroyed. As a result of experiments conducted by the author it was found that injecting a strong solution of copper sulphate in holes bored in the knots would destroy them to a considerable degree without injuring the trees. Out of 500 prune trees, about 200 were found upon examination to be infected and all were treated with the copper sulphate solution. After 2 years not one of the trees had died, but when examined all of the knots were dead. The success attained in this experiment has led the author to recommend this treatment.

The silver leaf disease, J. PERCIVAL (*Jour. Linn. Soc. [London], Bot., 35 (1902), No. 245, pp. 390-395, pl. 1, figs. 5*).—The disease known as silver leaf is, so far as the author is aware, confined to plants of the section Prunee, and has been the subject of investigation for fully a quarter of a century. The plum and peach seem to be most frequently attacked, but the apricot is not infrequently diseased, as well as some other species. The leaves of the diseased trees are generally normal in form and size, but their surfaces are of a peculiar ashy-gray color. The affected trees produce little or no fruit, and although the plants may live for a number of years before being killed they are always unprofitable. No spots or blisters are visible upon the leaves, and fungi are absent both in the affected leaves and the tissues of the stems and branches.

The author caused an affected plum tree to be dug up, and it was found that many of the roots were diseased. When cut across, the wood was discolored, and a microscopic examination of the discolored wood revealed the presence of fungus hyphae. Subsequently specimens of plum and apricot trees affected by the disease were received from a number of fruit growers and the roots were in every case found to be similarly affected. At first no fruiting organs could be discovered, but after several months' cultivation several sporophores of the fungus *Stereum purpureum* appeared. The constant presence of the fungus upon the roots of the trees led to the conclusion that it was responsible for the trouble, and inoculation experiments seemed to confirm this opinion. Inoculation made into branches caused the disease to show itself above the wound to the top of the shoot, but extended only a few inches below the wound.

From these experiments and other observations the author concludes that the sap

of the plant is the means of distribution of the trouble, and examination showed the presence of oxidizing ferments in the branches and cortex. Upon testing a number of diseased specimens the oxidase was found present in a soluble condition in all the diseased material but not in healthy trees. The conclusion is reached that the infection takes place below the ground, and whether other species of *Stereum* are capable of causing the disease is to be a subject of future investigation.

The olive knot in California, J. ISAAC (*California Bd. Hort. Rpt. 1901-2*, pp. 66-76, figs. 3).—The olive knot is said to be one of the most serious diseases of the olive tree, and although long known in Europe it did not make its appearance in California until 1893. The outbreak of disease noticed at this time was checked by the rooting out and burning of all diseased trees, and the disease was believed to be under control when a second and more serious outbreak was reported early in 1901. The disease, which is of bacterial nature and is due to *Bacillus olea*, is described at considerable length, frequent quotations being drawn from Italian and other investigators regarding the nature of the disease and its remedies. At present the olive knot is confined to a comparatively limited area and does not appear to be spreading, the diseased trees being destroyed as soon as observed. This method of treatment is believed to be the most efficient remedy. No varieties seem to be immune, although the Mission olive appears more resistant than any other. Whatever stimulates the growth of the tree appears to favor the spread of the disease, and where irrigation is practiced the appearance of disease can be controlled to a considerable extent by withholding water.

The fumagin of olives, E. ZACHAREWICZ (*Prog. Agr. et Vit. (Éd. L'Est)*, 24 (1903), No. 4, pp. 110-113).—A description is given of the fumagin, as well as of a second disease caused by the fungus *Cycloconium oleuginum*, which may be recognized by the presence on the leaves of black splotches which gradually spread, their centers and borders being differently marked. The infested leaves after a time turn yellow and fall from the trees. For the prevention of the attacks of these fungi the author recommends spraying the trees with a mixture composed of soap 1 kg., kerosene 4 liters, copper sulphate 1 kg., and water 100 liters. This should be sprayed over the trees, the first application about the middle of April to be followed by the second in a month or six weeks. In addition to describing these diseases, the author gives suggestions regarding the cultivation of the olive and the handling of its products.

Concerning the gooseberry mildew, P. MAGNUS (*Separate from Gartenflora*, 51 (1903), pp. 3; *abs. in Centbl. Bakt. u. Par., 2. Abt.*, 9 (1902), No. 19, p. 729).—A discussion is given of the distribution of *Sphaerotheca mors urae*. The author takes exception to the statement of others that this mildew is identical with *S. tomentosa*, which occurs on various species of Euphorbia. The mildews of the Euphorbia are said to be quite common throughout Germany in regions where the gooseberry mildew has never been known.

The gooseberry mildew in Russia, P. HENNINGS (*Ztschr. Pflanzenkrankh.*, 12 (1902), No. 1-2, pp. 16, 17).—The occurrence of the gooseberry mildew (*Sphaerotheca mors urae*) in different localities has led to a more extensive study of its distribution, and it is reported as occurring in different parts of Russia. The author believes that it is in all probability endemic to that country.

Oidium and early pruning, G. DARRAGON (*Prog. Agr. et Vit. (Éd. L'Est)*, 24 (1903), No. 4, pp. 121, 122).—Notes are given on the effect of early pruning for the prevention of powdery mildew. Vineyards that were pruned early in the winter and sprayed during the summer did not suffer from attacks of mildew, but those pruned late, even though frequently sprayed, were more or less subject to injury.

Report on a trip to Jamaica, F. S. EARLE (*Jour. New York Bot. Gard.*, 4 (1903), No. 37, pp. 1-10).—At the request of the director of the Jamaica Public Gardens the author made a visit to that island and presents some brief preliminary notes on a number of diseases of economic importance. Among the diseases noted are logwood

rot, cocoanut diseases, banana leaf blight, orange root grub, and several diseases of cacao.

The logwood root rot is said to be affecting the logwood trees, especially on the western end of the island, causing the destruction of many specimens. The diseased trees usually occur in groups, infection spreading slowly in constantly widening circles. The tissues are invaded by a white fungus mycelium, which seems to first attack the small rootlets, gradually spreading to the larger roots and finally to the crown, when the tree dies. The fungus causing this is probably one of the Hymenomycetes, and for the control of the disease the author recommends digging out and burning the roots of dead trees, or where a considerable area is infested, clearing the tract entirely of logwood and growing some crop that is not subject to the attack of this fungus.

Notes are also given on what is termed in the trade "bastard" logwood. This is a kind of logwood which contains little or no haematoxylin, but in its place a substance yielding a dull, yellowish-green dye. From various facts observed by the author it is believed that this is probably due to some hereditary trait on the part of the plant, as only certain trees produce this form of wood, and they apparently are reproduced from seed. Considerable variation has been noted in specimens of logwood and it is thought probable that there may be a varietal difference.

Among the diseases of cocoanut a description is given of a bud disease in which the first symptom is the dropping of the immature nuts. The head of the tree is in all cases invaded by what seems to be a bacterial rot, and bacteria are believed to be the cause of the trouble. It is claimed by some planters that a green-skinned variety of cocoanut is less liable to this disease than others, and facts observed seem to support this view. A second disease is reported in which the nuts fall a few at a time, the lower leaves droop and fall prematurely, and in the final stages the leaves are less than half normal size and are borne at the apex of the nearly bare stem. The course of this disease is always slow, but the affected trees ultimately die. In all the trees examined a white scale insect was always found at the base of the petioles and on the fruiting peduncles, but these insects did not seem to be numerous enough to account for the serious effect produced on the tree. It is said that badly affected trees have recovered when subjected to a firing of the dead leaves and fibers hanging on the trees. The flames kill all the fruit and open flowers as well as most of the expanded leaves, but the apical buds are not injured and new leaves and flowers soon develop. The work of the cocoanut trunk borer and the trunk rot, which are perhaps somewhat related, is described.

A banana leaf blight, which causes the browning of the vascular bundles in the veins and midribs of the leaves and eventually the decay of the leaf, is described. The infected plants are commonly stunted in growth and do not bear fruit, and there seems to be evidence that the disease is contagious. It is believed to be of bacterial origin and so far is confined to one locality.

The work of the orange root grub (*Præpodes vittata*) is described, the grub gnawing the roots and ultimately destroying the trees.

Among the cacao diseases mentioned is a stem canker, which is probably due to some form of *Nectria*, as the yellow perithecia were found abundantly developed on the bark. It is believed that painting the cankers and spraying the trees with Bordeaux mixture would protect the trees against this disease. A cacao pod rot, which is apparently of fungus origin, is briefly mentioned. It has as yet not attracted much attention, but is liable to prove destructive, particularly with certain varieties grown at low altitudes. A root disease, somewhat similar to that mentioned above as affecting the orange, is also noted.

A root rot of cassava was observed, in which the plants were somewhat similarly affected as the logwood trees described above. The cassava had been planted on

lands from which logwood trees had been cut, and it is possible that some relation exists between the root rots of these two plants.

Fungus cultures in the tropics, C. HOLTERMANN (*Ann. Bot. Gard., Peradeniya*, 1 (1901), pp. 27, pl. 1; *abs. in Bot. Centbl.*, 90 (1902), No. 8, pp. 207, 208).—It is stated that the excreted gum of the sugar palms (*Arenga saccharifera* and *Caryota urens*) when diluted in water and properly sterilized proves excellent media for the cultivation of different genera of fungi. It is further observed that the germinating spores of *Homileia vastatrix*, the fungus which causes the destructive coffee leaf disease, showed that the hyphae never possess transverse walls. This fact the author considers as indicating that the fungus does not belong to the Uredinæ, where it has been previously classed.

Comparative investigations of certain germicides, G. WESENBURG (*Centbl. Bakt. u. Par., 2. Abt.*, 8 (1902), No. 20, pp. 627-638; *abs. in Jour. Roy. Micros. Soc. [London]*, 1902, No. 4, p. 472).—A series of experiments was conducted to test the relative value of a number of substances which are offered for sale as fungicides. Antigermin was found to be a copper salt compound, with some weak organic acid. It is odorless, of a greenish color, and requires about 200 parts of hot water to completely effect solution. Mikrosol is a greenish paste of some copper compound. Afral is an organic compound, probably a nitro product of phenol. Antiformin is a chlorin compound similar to eau de Javelle. The effect of these various fungicides was tested on *Oidium lactis*, *Penicillium glaucum*, dry rot of timber, etc., and Antigermin was found to be the best preventive against the attacks of the dry rot, and it and Mikrosol were almost equally effective in destroying yeasts and molds. The other fungicides were found to be much weaker in their action.

The copper content of fungicides, with special reference to the copper poisoning of soils, K. SAJO (*Prometheus*, 14 (1902), No. 685, pp. 129-132).—The author discusses the composition of Bordeaux mixture, soda-Bordeaux mixture, eau celeste, etc., with special reference to the possibility of their injurious effects on soils when applied to plants for a long series of years.

Plant pathology, E. ROSTRUP (*Plantepatologi. Copenhagen*, 1902, pp. 640, figs. 259).

ENTOMOLOGY.

Insects of the year (*California Bd. Hort. Rpt. 1901-2*, pp. 89-172, figs. 72).—*South African black-scale parasite (Scutellista cyanea)* A. CRAW (pp. 91, 92).—This parasite was imported from Cape Colony and has become established in California. Observations thus far made upon this insect indicate that it is an exceedingly effective agent in the destruction of the black scale.

California peach-root borer, E. M. EHRHORN (pp. 93-102).—Notes are given on the appearance of the insect in its various stages and on its life history and habits. The methods recommended for destroying this species are digging out, the use of carbon bisulphid, strong washes, tobacco, gas lime, paper and other barriers around the trees, and a mixture of lime, coal tar, and whale-oil soap. The last named remedy is said to give the best results.

Insects as distributors of human diseases (pp. 103-114).—A brief discussion of the agency of mosquitoes and other insects in the transmission of malaria, typhoid fever, yellow fever, etc.

Locusts (pp. 115-125).—A number of species of locusts are annually injurious in California and occasionally certain species become unusually abundant. Notes are given on the life history of these insects and on the natural enemies and artificial remedies for their control.

Plant lice (pp. 126-137).—Economic and biological notes on woolly aphid, cabbage louse, wheat aphid, hop louse, black peach aphid, and cherry aphid.

Army worm (pp. 138-146).—Notes on the habits, life history, and means of combating *Leucania unipuncta*.

Cankerworm (pp. 147-150).—Brief notes on the spring and fall cankerworm. Paris green is recommended as the most efficient remedy for destroying this insect.

Screw-worm fly (pp. 151-153).—This insect was exceedingly injurious in the San Joaquin Valley 2 years ago. Recently, however, it has nearly disappeared, apparently on account of the unusually cold winter just experienced.

Notes are also presented on codling moth traps, a jumping gall, and on the collection and preservation of insects.

Horticultural quarantine reports, A. CRAW (*California Bd. Hort. Rpt. 1901-2, pp. 187-204*).—Detailed notes are given on the injurious insects detected in fruit and other material imported into California and on various measures which have been taken for controlling insect pests in this State. A number of colonies of *Vedalia cardinalis* have been sent to various parts of the world for the purpose of destroying scale insects. The parasite of the black scale received from Cape Colony is reported as in good condition and apparently destroying the scale at a rapid rate.

Proceedings of the Entomological Society of Washington (*Proc. Ent. Soc. Washington, 5 (1903), No. 2, pp. 93-166, figs. 21*).—As usual, notes are given on the discussions and resolutions at the various meetings of the society during the year. A number of special articles were read, and these are printed in the present number of the proceedings. Some of these articles are of economic importance, while others are merely of scientific interest. Special mention may be made in this connection of the following articles:

Note on a California fruit worm, H. G. Dyar (p. 104).—This insect was found infesting dried fruit and proved to be *Titula serratilineella*.

Observations on the habits of two Cicindelids, J. D. Mitchell (pp. 108-110).—These insects are *Tetracha carolina* and *Cicindela rectilata*.

Collecting notes on mosquitoes in oriental countries, C. L. Marlatt (pp. 111-123).—Biological and economic notes are given on the mosquitoes of Japan, China, Java, and Ceylon.

Notes on the periodical cicada in the District of Columbia in 1902, C. L. Marlatt (pp. 124-126).—It is stated that in the City of Washington very few of the cicadas which emerged survived for more than 2 hours, being quickly destroyed by the English sparrows.

Synopsis of the North American species of Erebia, and *The life history of Callizzia amurensis*, H. G. Dyar (pp. 129-133). *A chalcidid parasite of the Asiatic ladybird*, C. L. Marlatt (pp. 138, 139). *Notes on mosquitoes in New Hampshire*, H. G. Dyar (pp. 140-148). *Some new or unreported Orthoptera from Arizona*, A. N. Caudell (pp. 162-166).

Report on injurious insects in Finland for the year 1901, E. REUTER (*Landbr. Styf. Meddel. [Helsingfors], 1902, No. 39, pp. 74*).—The larger part of this report is occupied with an account of the insects which are injurious to grasses and cereals, especially the insects which produce silver-top condition in these plants. An account is given of the extent to which silver-top condition prevailed in various parts of Finland during the year and of the insects which were chiefly instrumental in causing this damage. A large number of insects produce this effect, chief among which the author mentions species of Lasiptera, *Pseudococcus*, *Isosoma*, *Pediculoides graminum*, *Tarsonemus culmicolus*, *Aptinotrips rufa*, and *Eriophyes cornutus*. The amount of damage caused by these insects upon various species of meadow grasses is shown in tables, and an alphabetical list of species of grasses is given, together with the species of insects injurious to each grass.

A brief catalogue is also presented of the insects which cause silver top in grasses, arranged in a systematic order. For the purpose of preventing the injuries thus caused to grasses the author recommends immediate harvesting of the grass as soon as the damage begins to appear, and subsequent treatment by removal from the field

and by other methods so as to prevent the undue spread of the insects. The species which were found to be specially injurious to cereals were *Phyllotreta vittula*, *Rhizoglyphus echinopus*, *Oscinis frit*, *Oiceoploma opaca*, etc. Notes are also given on insects which were most conspicuous as enemies of garden crops, fruit trees, and on ornamentals. Brief notes are given on injuries from ants.

Report of the State entomologist for 1901, S. LAMPA (*Ent. Tidskr.*, 23 (1902), No. 2-3, pp. 65-116, figs. 6).—As usual in these reports, the author presents an account of the insect injuries to various crops in different parts of Sweden, together with special notes on insects of unusual importance. In the present report notes are given on a large number of injurious insects, including gypsy moth, nun, diamond-back moth, cabbage butterfly, blister beetles, cutworms, *Agriotes lineatus*, *Melolontha vulgaris*, pea weevil, bean weevil, *Apion apricans*, *Tomicus dispar*, codling moth, *Argyresthia conjugella*, etc. Notes are also presented on experiments in spraying various crops with Paris green and pyrethrum.

Report on the work of the section of plant protection from April 1, 1901, to March 31, 1902, C. BRICK (*Sta. Pflanzenschutz, Hamburg*, 4 (1901-2), pp. 1-10).—The number of packages of apples introduced from America during the year was 30,684. Of this number, 4,095 were infected with San José scale. The percentage of infested fruit varied greatly according to the part of the United States from which they came, 8.96 per cent of the apples from the Eastern States, 25.72 per cent of those from California, and 99.55 per cent of those from Oregon being infested. The San José scale and other scale insects were also found to a slight extent on other fruits from North and South America. No specimens of San José scale were found upon living plants or parts of plants introduced from the United States.

Notes on certain injurious insects, A. HEMPEL (*Bol. Agr. São Paulo*, 3. ser., 1902, No. 4, pp. 237-255).—The author presents an analytical table for identifying the various groups belonging to Hemiptera and Homoptera. Special attention is given to biological and economic notes on injurious plant lice and scale insects. The insecticides most strongly recommended for destroying these insects include kerosene emulsion, sheep dip, and carbon bisulphid.

The changa, or mole cricket (*Scapteriscus didactylus*), in Porto Rico, O. W. BARRETT (*Porto Rico Sta. Bol.* 2, pp. 20, fig. 1).—This insect is described in its various stages and notes are given on its life history, habits, and the most approved means for combating it. The eggs are laid in the underground galleries of the insect from a few inches to a foot or more beneath the surface of the ground. The eggs are deposited from January to March and hatch in about 2 weeks. The immature changa seldom leaves the soil, but adults are frequently seen, especially at night. The adult males may be readily attracted to lights. The plants which are most injured by changa are cane, tobacco, and rice. Other crops are somewhat damaged, such as tomato, eggplant, cabbage, etc. The insect was not considered a serious pest until after 1876. It is less injurious in the mountain districts where the soil is clayey than in the sandy loams of the valleys. The greatest injuries are done from October to December.

A large number of remedies have been tried against this insect, with various results. Tobacco plants may be protected by a wrapping of leaves of *Mammea americana*, or wire gauze. Cheese cloth, mulches of tobacco stems beneath the surface, pomace from castor-oil presses, and coal-tar barriers have been tried, without much success. Clean cultivation is effective if persisted in for some time. Lantern traps which emit an intense light have been found quite useful in attracting the insects. Naphthalin is found to be one of the best repellent remedies. Carbon bisulphid was effective, but rather too expensive. Creosote and creolin exhibit little or no repellent action. Kerosene appeared to be effective, but injured the plants to some extent. The best artificial remedy was found to be a poison bait prepared by sprinkling

chopped grass with arsenic or Paris green and placing this material upon or just beneath the surface of the soil.

The most important natural enemy of the changa is the native species of blackbird. Other species of birds have been observed feeding upon the changa.

Army worms on millet, G. D'UTRA (*Bol. Agr. São Paulo, 3. ser., 1902, No. 3, pp. 158-162*).—Notes on the habits and life history of *Leucania unipuncta* and on means of combating this insect in millet fields.

Methods of controlling the boll weevil, W. D. HUNTER (*U. S. Dept. Agr., Farmers' Bul. 163, pp. 16, figs. 2*).—The Division of Entomology has a contract whereby certain planters agree to manage the cotton crop in certain locations under the directions of the Division. About 350 acres were managed in that way during 1902. The cotton-boll weevil, while confined to Texas, occupies about 28 per cent. of the cotton acreage of the United States. It has been shown, however, that cotton can be grown profitably in spite of the attacks of this insect. The author believes that the weevil will ultimately be distributed all over the cotton belt, since there are no influences which can check its distribution. The author mentions a number of methods which are ineffective in combating the weevil. These include various nostrums, machines, and the use of cotton-seed meal. It was found that the various varieties of Egyptian cotton are more susceptible to damage by the weevil than are the ordinary varieties of American upland cotton. The remedies which are recommended for controlling the weevil include early planting, thorough cultivation of the fields, destruction of all cotton stalks in the fall not later than the first week in October, planting the rows far apart, and thinning out the plants in the rows.

Potato insecticides and fungicides in 1902, C. D. WOONS (*Maine Sta. Bul. 87, pp. 197-209*).—A number of insecticides were used in combating the potato beetle, among which mention may be made of Paris green, arsenate of lead, Black Death, Quick Death, English Bug Compound, Kno-bug, and Hammond's Slug Shot. A test of the value of Kno-bug as a fungicide was made by the station with the result that the yield was found to be much less on plats treated with this substance than on others treated with Bordeaux mixture. The disease which affected the potatoes in this experiment was rot. An analysis of Kno-bug showed it to contain only about 2½ per cent of Paris green, while 88 per cent was ordinary land plaster.

An experiment was instituted for the purpose of testing the relative value of Paris green, Bug Death, and arsenate of lead in combating potato bugs. The amounts of Bug Death used were those recommended by the manufacturers. The field was sprayed 5 times. The results of these experiments are presented in detail. It was found that at no time was there any noticeable difference in the color, size, or vigor of the vines treated with the different substances. Paris green kept the vines rather freer from potato bugs than did Bug Death or arsenate of lead. In an experiment conducted by E. A. Rogers potatoes treated with Bug Death were found to yield more heavily than those sprayed with Paris green or other insecticides. These results, however, were not confirmed by the station work.

Insects injurious to Cucurbitaceous plants, H. A. SURFACE (*Pennsylvania Dept. Agr. Bul. 96, pp. 30, pls. 24*).—The insects which most commonly attack cultivated cucurbits are discussed in systematic order and notes are given on the best remedies for combating the different species. The insects to which most attention is given are onion thrips, squash bug, melon louse, cucumber louse, pickle moth, melon worm, squash borer, *Epilachna borealis*, cucumber beetles, flea-beetles, and undetermined fly larvae. Occasional injury is noticed from *Limax*, centipedes, and earth worms.

The remedies discussed by the author include net covering, paper tent for fumigating with bisulphid of carbon, tarred board, board traps, various cultural remedies, such as clearing up rubbish, killing weeds, rotation of crops, use of trap crops, hand picking, fertilizers, late fall plowing, early planting, excessive seeding, and the use

of insecticides, such as Paris green, London purple, arsenite of lime, kerosene in emulsion and in mechanical mixture with water, whale-oil soap, carbon bisulphid, gasolene, calcium carbide, tobacco, sulphur, and lime.

Some garden pests, W. W. FROGGATT (*Agr. Gaz. New South Wales*, 13 (1902), No. 12, pp. 1167-1173, pls. 2).—Brief notes are given on the habits, life history, and means of combating *Helix aspersa*, *Siphonophora rosea*, fluted scale, red orange scale, and various species of butterflies which are more or less injurious to garden crops.

Combating the enemies of asparagus, K. SAJO (*Prometheus*, 13 (1902), Nos. 656, pp. 497, 498; 657, pp. 521-524).—Notes are given on the habits and life history of *Platyparva pœcilopectera*, the 12-spotted and 14-spotted asparagus beetles, asparagus rust, and *Agromyza maura*.

Codling moth, R. A. COOLEY (*Montana Sta. Bul.* 42, pp. 18).—The codling moth has not yet become established in commercial orchards in Montana. The insect has been found in Missoula, Thompson Falls, Helena, and Kalispell. According to the author's observations larvæ of the first brood were found in 50 out of 323 apples, and when the second brood appeared 115 out of 144 apples were infested, while the amount of destruction was placed at about 51 per cent. It is believed that birds assist considerably in destroying these insects. In the Bitter Root region an insect, which was apparently not codling moth, was found infesting the apple. Notes are given on the habits and life history of codling moth. In Montana it is believed that there are 2 broods per year. Paris green is recommended as an insecticide, together with the use of bands.

Codling moth, K. SAJO (*Prometheus*, 13 (1902), Nos. 661, pp. 577-580, fig. 1; 662, pp. 593-596).—A popular account is given of the habits, life history, and means of combating the codling moth as shown by the experimental work of investigators in various countries.

Biological investigations of the nun (*Lymantria monacha*), its parasites and diseases, S. BENGTSSON (*Ent. Tidskr.*, 23 (1902), No. 2-3, pp. 125-194, pls. 2).—On account of the unusual destruction caused by the nun in various parts of Sweden an investigation of the habits of this insect with special reference to successful means of combating it was instituted by the Swedish government. The present report contains an extensive account of the life history and habits of this insect, the bacterial and fungus diseases which have been found attacking it, and notes on the various insects which live upon it as parasites. As a result of these investigations it is concluded that the only successful way of fighting the nun on a large scale consists in banding the trees with some sticky preparation and utilizing badly infested trees for fuel and manufacturing purposes.

The brown-tail moth in Massachusetts, A. H. KIRKLAND (*Trans. Massachusetts Hort. Soc.* 1902, I, pp. 12-21).—The author discusses the early European history of this insect and an account is given of its introduction and spread in America. The best results in controlling the insect have been obtained from the use of arsenate of lead and kerosene emulsion.

The woolly aphid on the roots of apple trees, C. RITTER (*Ztschr. Pflanzenkrankh.*, 12 (1902), No. 1-2, pp. 7-10, pl. 1).—Brief notes are given on the appearance of galls caused by woolly aphid on the roots of apple trees. The insects were observed also on the roots of young pear trees. The author knows of no effective means for preventing the ravages of this insect provided it should attack young trees. The use of lime is recommended, together with the destruction of badly infested trees.

The mango shield scale (*Agr. News [Barbados]*, 2 (1903), No. 21, p. 40).—Notes are given on *Lecanium mangiferae*, which is becoming rather injurious in the West Indies. The chief natural enemy of the insect is a fungus disease which manifests itself as a white mold upon the dead scales.

Distinctive characteristics of the species of the genus *Lecanium*, W. C. THRO (*New York Cornell Sta. Bul.* 209, pp. 201-221, pls. 5).—Detailed notes are given

on the external anatomical characters of the genus *Lecanium* with special reference to features which may be used in distinguishing the species. A number of species of this genus are described by way of illustration of the use of these anatomical features, and an analytical key is presented for the identification of the species described.

The development of the cherry fly, K. SAJO (*Prometheus*, 14 (1902), No. 679, pp. 33, 34).—Notes are given on the life history and habits of *Spilograpta cerasi*. In the opinion of the author it is still doubtful whether there are two different races of this species, of which one completes its life cycle in 1 year while the other requires 2 years for full development.

The frit fly (*Oscinis frit*) (*Landtmannen*, 14 (1903), No. 4, pp. 57-60).

The grape-root worm—further experiments and cultural suggestions, M. V. SLINGERLAND and J. CRAIG (*New York Cornell Sta. Bul.* 208, pp. 173-200, pls. 8).—The present distribution of this species is from the Middle States to Dakota and south to Florida and Texas. In New York it has proved injurious only in Chautauqua County, where it appears to attack chiefly vineyards which have been neglected from a cultural standpoint. Many vines are killed outright and most of them are weakened so that they are practically ruined. Notes are given on the life history and habits of the beetle. The natural enemies of this insect in New York so far as observed are chickens, ants, and a few species of birds.

The remedial measures undertaken by the authors included fertilizer experiments and attempts to use native grape roots resistant to the attacks of the grubs. The roots of a number of native types of American grapes have been used and subsequently grafted with the standard varieties grown in Chautauqua County, but 2 or 3 years will be required before definite results are known. Experiments with fertilizers indicate that many injured vineyards can be invigorated by proper application of these substances. The best results were obtained from thorough cultivation of the soil. It is believed that if the soil is cultivated thoroughly in June and July the grape-root worm will be prevented from becoming a serious pest. The cases in which the pupae lie are thus broken up and the insects fail to reach the adult stage. Experiments with insecticides were not so favorable, and the authors believe that more can be done by cultivation than by the use of poisoned sprays. Jarring the beetles was found to be a laborious method, and while more or less effective is not considered very practicable for ordinary use. Brief notes are given on the fertilizers best adapted for use in vineyards and on the proper cultural methods.

Tortrix pilleriana, J. DUFOUR (*Chron. Agr. Canton Vaud*, 15 (1902), No. 24, pp. 682-688, figs. 7; 16 (1903), No. 2, pp. 31-34).—A method much used in certain parts of France for controlling this insect consists in the application of hot water to the pruned grapevines. In recent years a number of experiments have been made with solutions of acids, during which sulphuric, nitric, and hydrochloric acids were used. The best results were obtained by spraying the grape stock with a 10 per cent solution of sulphuric acid in water.

Insects affecting forest trees, H. OSBORN (*Jour. Columbus Hort. Soc.*, 17 (1902), No. 3, pp. 79-92).—Notes on the habits and life history of bark beetles, banded hickory borer, white ants, San José scale, periodical cicada, dog-day cicada, willow sawfly, walnut caterpillar, fall webworm, white-marked tussock moth, Cecropia moth, American silkworm, bagworm, *Notodonta concinna*, and *N. unicornis*.

On the ravages of the spruce spinner (*Bombyx pini*), W. M. SCHÖYEN (*Norsk Landmandsblad*, 21 (1902), No. 48, pp. 577-582).

The biology of red spiders, R. VON HANSTEIN (*Ztschr. Pflanzenkrankh.*, 12 (1902), No. 1-2, pp. 1-7).—Notes are given on the habits and life history of *Tetranychus telarius* and *T. altwae*. These species are said to cause considerable injury to shade trees in Berlin and other cities where the author made investigation. The dry weather was favorable to the development and multiplication of both species. In combating these mites the author recommends the use of those remedies which are

applicable in the destruction of woolly aphis. On young trees or in situations where the application is practicable, tobacco dust and lime may be used with good effect. A number of natural enemies prey upon these species, especially the larvæ of *Chrysopa* and *Hemerobius*.

Notes on a *Phytoptus*, A. KEMPEL (*Bol. Agr. São Paulo*, 3. ser., 1902, No. 2, pp. 87-90, figs. 2).—The *Phytoptus fuchsiae* is said to be injurious to fuchsias and is described as a new species. It is said to be closely related to *P. oleivorus*. Considerable difficulty will usually be experienced in combating this insect, on account of the tender nature of the affected plants.

Combating injurious insects by means of their natural enemies, K. SAJO (*Prometheus*, 13 (1902), Nos. 667, pp. 673-676, fig. 1; 668, pp. 689-692, figs. 2).—The author presents a summary account of the results which have thus far been obtained in combating noxious insects by means of parasitic fungi and parasitic and predaceous insects.

Spray calendar, W. E. BRITTON and G. P. CLINTON (*Connecticut State Sta. Bul.* 142, pp. 19, figs. 4).—This bulletin is arranged in the form of an ordinary calendar and contains formulæ for preparing common insecticides and fungicides. The more important economic plants are arranged in alphabetical order, with brief notes on their insect and fungus diseases.

Spray calendar, N. O. BOOTH (*Missouri Sta. Circ. of Information* 10, pp. 13).—Brief notes are given on the efficacy of spraying and on methods of preparing fungicides and insecticides. A brief spraying calendar is given indicating the time of year and nature of the applications required for controlling the insect and fungus diseases of common economic plants.

Spray calendar, W. LOCHHEAD (*Ontario Agr. Col. and Expt. Farm Bul.* 122, pp. 12, fig. 1).—Formulæ are given for the preparation of Bordeaux mixture, copper sulphate, ammoniacal copper carbonate solution, potassium sulphid, Paris green, poison bait, hellebore, pyrethrum, kerosene emulsion, tobacco decoction, whale-oil soap, crude petroleum, lime wash, formalin, and carbon bisulphid. The chief enemies of a number of the more common economic plants are mentioned, together with remedies for combating these pests.

On the choice of a soft soap for hop spraying, C. DUNCAN (*Agr. Student's Gaz.*, n. ser., 11 (1902), No. 1, pp. 16-18).—The author presents notes on the means of detecting and estimating resin in soft soap, and also on methods for determining other constituents in these soaps with reference to their use and effectiveness in destroying hop insects.

Report of analyses of Paris green and other insecticides in 1902, L. L. VAN SLYKE and W. H. ANDREWS (*New York State Sta. Bul.* 222, pp. 263-268).—Analyses were made of 44 samples of Paris green, in which the amount of arsenious oxid varied from 55.39 to 61.4 per cent, averaging 57.1; the amount of arsenic soluble in water averaging 1.01 per cent. The quantity of copper oxid varied from 27.03 to 30.79 per cent, averaging 29.41. The average amount of arsenious oxid in combination with copper was 55.1. The results obtained during these analyses indicate that the Paris green found on the market during 1902 was of a satisfactory quality.

Hypoderma bovis, F. ETCHEGOHYEN (*Bol. Sec. Fomento [Mexico]*, 1 (1902), No. 11, 1, pp. 481-487).—Notes on the appearance, habits, life history, and means of combating this insect.

Sheep gadfly (*Jour. Bd. Agr. [London]*, 9 (1902), No. 2, pp. 217, 218).—Notes are given on the appearance and habits of *Estrus ovis*. In preventing the attacks of this fly it is recommended that a mixture of tar and fish oil in equal parts be smeared on the nose of the sheep.

Injurious household insects, S. LAMPA (*Ent. Tidskr.*, 23 (1902), No. 2-3, pp.

122-124).—Biological and economic notes are given on *Tinea pellionella*, *T. granella*, *T. tapetzella*, and *Tineola bisselliella*.

Remedies for fleas, A. F. CONRADI (*New Hampshire Sta. Bul.* 94, pp. 89-92).—A study was made of various remedies which may be applied in destroying the dog flea. Persian insect powder and hand picking were found to be too laborious methods or ineffective. The best results were obtained from the use of creolin washes. The animal may be thoroughly washed with the hands or a brush, or may be submerged for a period of 5 minutes in a solution of creolin. For dogs a 3 per cent solution is recommended, and for cats a 2 per cent solution. In addition to this treatment it is recommended that rugs be substituted for carpets, and that floors and resting places for dogs and cats be treated with a 5 per cent solution of creolin. Hydrocyanic-acid gas is recommended only as a last resort.

Mosquitoes in Algiers, EDMOND and ÉTIENNE SERGENT (*Ann. Inst. Pasteur*, 17 (1903), No. 1, pp. 60-67, figs. 14).—Brief notes on a number of species of mosquitoes collected within a radius of 15 km. of Algiers. In this region 9 species were observed, 3 of which are described as new. The new species are *Anopheles algiersensis*, *Culex sergentii*, and *C. marie*.

Forest mosquitoes and forest malaria, A. LUTZ (*Centbl. Bakt. u. Par.*, 1. Abt., 33 (1903), No. 4, Orig., pp. 282-292, figs. 7).—The author discusses the occurrence and frequency of different species of mosquitoes in the forested districts. A number of plants have been found which furnish receptacles at the bases of the leaves or in specially modified portions of the leaves in which sufficient water may be contained to serve as breeding places for mosquito larvæ.

Description of a new Anopheles, C. S. LUDLOW (*Jour. Amer. Med. Assoc.*, 39 (1902), No. 8, pp. 426, 427).—In the Philippine Islands a number of species of mosquitoes have been found, including *Stegomyia fasciata*, *Culex fatigans*, *Panopiles africanus*, and *Anopheles philippinensis*, the last species being described as new.

Combating Anopheles, D. RIVAS (*Centbl. Bakt. u. Par.*, 1. Abt., 33 (1902), No. 2, Orig., pp. 235-238).—Glass vessels were filled nearly full of water and a film of kerosene was gradually spread over the surface. The eggs of *Anopheles* were then placed upon the surface, and after 2 or 3 days it was found that a number had sunk to the bottom. Some of the larvæ, however, developed, but for the most part rather weakly. In other vessels which were covered with a film of machine oil the larvæ appeared to develop as vigorously as in pure water. The author therefore made use of kerosene exclusively in destroying the eggs, larvæ, and pupæ of mosquitoes in pools and bodies of stagnant water.

Report of the Agricultural and Mechanical College apiary, F. W. MALLY and W. NEWELL (*Austin, Tex.: Von Boeckmann, Schutze & Co., 1902*, pp. 53, pl. 1, figs. 29).—An appropriation was made by the State of Texas for the purpose of establishing an experimental apiary under the direction of the State entomologist. Notes are given on the establishment of this apiary and on certain experiments which were conducted during the first year. It is proposed to study different races of bees and to determine as nearly as possible the comparative length of life of bees of different races. Special attention is given to a study of varicose drought-resistant bee plants. A large number were found to be partial or total failures. These include a number of native species of leguminous plants, as well as various clovers, English rape, soy bean, velvet bean, etc. Japanese buckwheat gave the best results, while fairly good results were obtained from black mustard, mignonette, and borage. It is stated that in Uvalde County colonies of bees in average seasons yield from 100 to 200 lbs. of honey. A practical manual of bee keeping was compiled and presented as the second part of the report. This contains a discussion of the various matters relating to the care and management of bees.

Annual report of the Royal Sericultural Station at Padua (*Ann. R. Staz. Bacol. Padova*, 30 (1901), pp. 121, pl. 1, figs. 3).—A brief summary of the work of the

station is given by the director, E. Verson. The report also contains a number of articles dealing with various phases of sericulture, and the following brief notes are made upon these articles:

The fluids which cause the loosening of the skin in the molting process of insects, E. Verson (pp. 17-32).—Notes are given on the specialized cells which produce this fluid in insects. The author's observations and studies were confined largely to the silkworm, and his results are compared with those obtained by W. L. Tower in a study of the potato beetle.

Impermeability of the cell of the silkworm egg to alcohol, E. Quajal (pp. 33-36).—An investigation of this subject showed that the immersion of eggs of various races of silkworms for periods varying from 5 to 50 minutes in alcohol did not cause any injury to the eggs, since the shell did not appear to be penetrated by the alcohol.

The effects of prolonged hibernation on the silkworm eggs of various races, E. Quajal (pp. 40-49).—A summary account is presented of experiments along this line conducted during the years 1899-1901. It was found that the Chinese race of silkworms was most susceptible to the injurious effects of prolonged low temperature, while the yellow Asiatic race appears to be much less affected by this agency.

Influence of external conditions upon the physical properties of cocoons, E. Verson (pp. 50-54; 73-80).—The author's experiments were made on 2 races, the Sciaohing and Sierra Morena. The experiments were confined to a test of the effect of methods of feeding and different feeding stuffs upon the color, elasticity, and tenacity of silk.

The number of silkworm moths which can be fertilized by a single male, E. Quajal (pp. 55-72).—A considerable variation was observed in different races, the number of females fertilized by a single male varying from 3 to 15.

Brief notes are also given on spermatogenesis of insects as related to the silkworm, and on the influence of dry and moist air during the spinning and maturation period of the pupæ. An elaborate bibliography of publications relating to sericulture which appeared during the years 1901 and 1902 is also given (pp. 97-120).

Experiments at the Sericultural Station of Murcia for 1902, E. LOPEZ (*Cartilla para la crianza y ahogado del gusano de la seda. Levante, 1902, pp. 6*).—Brief notes on the incubation of silkworm eggs and on the relative numbers which proved to be fertile or infertile.

Rearing and killing silkworms, E. LOPEZ (*Levante: Min. Agr. Ind. and Com., 1902, pp. 23*).—Brief notes on the cultivation of mulberries and on the various processes concerned in rearing and killing silkworms.

The silkworm in Spain, A. E. CARLETON (*U. S. Consular Rpts., 71 (1903), No. 270, pp. 418, 419*).—In 1901 the silkworm crop of Spain is said to have been considerably below that of 1900. The French species of silkworm continues to be cultivated more than other varieties.

Silkworms in Italy, W. JARVIS (*U. S. Consular Rpts., 71 (1903), No. 270, pp. 419, 420*).—The breeds of silkworms cultivated in Italy are stated as being the pure yellow, the white indigenous, and the Japanese cross. The only silkworms bred in Italy are those which feed on the mulberry leaf. Brief notes are given on the planting and care of mulberry trees and on the rearing and value of silkworms in Italy.

FOODS—NUTRITION.

Food adulteration, F. W. TRAPHAGEN (*Montana Sta. Bul. 38, pp. 24*).—The examination of a large number of foods and condiments showed that food adulteration was common in Montana. In connection with this work proximate analyses were made of samples of crackers, biscuits, cereal breakfast foods, baking powders, flours, and vinegars.

The detection of a small amount of salicylic acid in a sample of jam, which there was reason to believe contained no added preservative, led the author to study the

natural occurrence of salicylic acid in fruits. Its presence was demonstrated in strawberries, red and black raspberries, blackberries, currants, plums, black cherries, apricots, peaches, Concord grapes, crab apples, standard apples, quinces and oranges, and also in tomatoes, cauliflower, and string beans. In a few instances quantitative determinations of salicylic acid were made showing the following amounts in milligrams of acid per kilogram of fruit: Currants 0.57, cherries 0.46, plums 0.28, crab apples 0.24, grapes 0.32. These values are not regarded as absolute, since check analyses made with known amounts of salicylic acid showed that not nearly all the acid was extracted by the method followed. The author states that he distilled the fruit with phosphoric acid, extracted the distillate with ether, took up the resulting material with a small amount of water and applied the ferric chlorid test after the ether had evaporated.

Occurrence of salicylic acid in fruits, F. W. TRAPHAGEN and E. BURKE (*Jour. Amer. Chem. Soc.*, 25 (1903), No. 3, pp. 242-244).—Noted above from another source (see above).

Food adulteration, E. F. LADD (*North Dakota Sta. Bul.* 53, pp. 115-151).—With the view of detecting added coloring matters, preservatives, and adulterants, analyses were made in accordance with the State pure-food law of a number of samples of jams, jellies, and similar products, catsups, canned soups, canned vegetables, pork and beans, extracts, candies, cream of tartar, and spices. Analyses are also reported of a number of samples of cereal breakfast foods, pancake flours, plasmon and plasmon biscuit, nutrium, and milk flour. It is the author's opinion, based on the results of his investigations, that the law to prevent food adulteration is not being complied with by the producers whose goods are sold in the State, and that some active measures are necessary.

Cereal breakfast foods. A. MCGILL (*Lab. Inland Rev. Dept. Ottawa, Canada, 1902, Bul.* 84, pp. 31, pl. 1).—Analytical methods are discussed and detailed analyses reported of a number of samples of malt breakfast foods, oatmeal and other breakfast foods, pea meal, and corn meal. Special interest attaches to the determination of starch in the malted products, as it is claimed by the manufacturers that in such goods insoluble starch has been largely converted into soluble bodies. The author states that oatmeal gave but 3.85 per cent of material soluble in cold water, while several of the specially prepared foods gave 20 per cent or more. Many of the cereal foods had been cooked more or less during the process of manufacture. According to the author "the chief object sought in boiling porridge is to render the starch soluble; and where conditions make it difficult or impossible to properly cook one's porridge, there is doubtless an advantage in using a material that has already undergone some change in this regard. Whether or not the high prices at which these foods are sold are sufficiently warranted by the saving of fuel and time, under ordinary conditions of domestic life, is a question to be solved by each housekeeper for himself.

"There is, however, another point of view from which these foods may be regarded, viz, their content in proteid matter. In this respect pea meal excels them all. There is, however, good reason to believe that the proteids of the pea and bean, and of leguminose in general, are less easily digested by man than are the proteids of the cereal grains proper. Among these oatmeal takes first rank, but several of the prepared foods stand very well in this regard. If we take into account the mineral matter (ash) which is no less necessary to complete nutrition, we find marked differences among these foods. If one were to live entirely or principally upon these foods, it would be very necessary to take account of this. Finally, on account of its very high energy factor, we may lay stress upon the content of fat; and here also oatmeal stands in the first place."

Estimating the value of wheat and wheat flour by means of baking experiments, K. KOMERS and E. VON HAUNALTER (*Ztschr. Landw. Versuchs. Oesterr.*,

5 (1902), No. 11, pp. 1225-1265, fig. 1).—The authors discuss critically the usual methods of testing the baking quality of flour and believe that this may be satisfactorily learned by the aid of laboratory baking experiments. The importance of working with dough of uniform consistency and using zymine as a ferment is insisted upon. According to the authors, the volume of the sample of baked bread may be best determined by coating the bread with paraffin and noting the amount of water displaced in a piknometer of suitable form (which is described), corrections of course being introduced for the amount of paraffin adhering to the bread.

Examination of artificially colored barley grits, E. KRAMER (*Ztschr. Landw. Versuchs. Oesterr.*, 5 (1902), No. 4, pp. 588, 589).—Analytical data are reported and discussed.

Desiccated meat, F. B. GUTHRIE (*Agr. Gaz. New South Wales*, 13 (1902), No. 12, pp. 1248, 1249).—Methods of drying meat so that it can be reduced to a powder, which may be stored without deterioration, were studied, as well as the digestibility of such products. The most satisfactory results were obtained when meat, ground in an ordinary sausage cutter, was spread on a fairly open sieve in a drying oven. This permitted the melted fat to run away and, it is said, greatly expedited drying.

"The oven was left open so as to allow free access of air, and after 4 hours drying, at a temperature of 65 C. to 70° C. (and which never rose above 70° C.) the product was sufficiently dry to be readily reduced to a fairly fine powder in an ordinary mill. The product obtained at this temperature is a light-colored, slightly reddish powder containing 11 to 12 per cent water, of an agreeable odor and exceedingly palatable, especially if a little salt is added. It keeps perfectly in stoppered vessels. A sample prepared in a very similar way in June, and placed in an ordinary corked flask, is still perfectly sweet 4 months later, though the cork has been frequently removed during that time. If packed in air-tight tins, or in tins from which all air has been excluded, there is every reason to suppose that the powder will keep for an indefinite period. The time taken in drying could no doubt be considerably shortened if a fairly rapid current of dry air were passed through the drying chamber during the process. This was not found practicable with the appliances available, as it was impossible to prevent the accumulation of moisture on the walls and ceiling of the oven."

As shown by artificial digestion experiments 96 per cent of the dry matter of the desiccated beef was digestible as compared with 96.6 per cent from fresh raw beef.

Examination of meat juice, R. VOGEL (*München. Med. Wochenschr.*, 1902, No. 17, p. 6; *abs. in Ztschr. Fleisch. u. Milchhyg.*, 12 (1902), No. 11, p. 352).—According to the experiments reported, juice can not be extracted normally, even under high pressure, from freshly slaughtered, i. e., living muscular tissue. When muscle cells die their proteid contents begin to liquefy, the amount of liquefaction being proportional to the temperature. Meat juice is regarded as a product of post-mortem proteolysis, that is, as due to a form of autolysis of the muscles and not to decomposition or to the formation of acid. It is considered as a part of an extended cleavage of the protein molecule. Unorganized ferments are regarded as the cause of this muscle autolysis, although they were not identified. The characteristics of the fresh meat juice are discussed and its food value is pointed out, attention being directed especially to the fact that it is useful when less than ordinary work should be required of the digestive organs and a liquid diet is indicated.

Identification of horse flesh by means of a specific serum, G. GRÖNING (*Ztschr. Fleisch. u. Milchhyg.*, 13 (1902), No. 1, pp. 1-4).—According to the author the subcutaneous injection of the juice of horse meat produces a serum in the blood of rabbits which serves for the identification of horse meat when it has not been cooked or heated. When even a trace of solution containing horse flesh is added to the clear yellow serum a cloudiness is observed and later a precipitate. Precautions necessary in the use of the serum are noted.

On certain exotic Graminæ used as food, BALLAND (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 23, pp. 1079, 1080).—Analyses are reported of the seeds of *Elusine stricta*, *Paspalum frumentaceum*, *P. longiflorum*, and *P. scrobiculatum*; hulled *paspalum*, called "fonio;" *Penicellaria spicata* (*Penicetum spicatum*), *Holcus sorghum* (*Sorghum vulgare*), and "Tef," or *Poa abyssinica*.

Lime juice and catsup, A. MCGILL (*Lab. Inland Res. Dept. Ottawa, Canada*, 1902, *Bul.* 83, pp. 19).—Twenty-six samples of catsup and 27 samples of lime juice were examined. A considerable amount of data is summarized regarding the physiological effects of coloring matters and preservatives, and facts regarding the occurrence of both in catsup and of the latter in lime juice are reported.

Unfermented grape juice, T. MACFARLANE (*Lab. Inland Res. Dept. Ottawa, Canada*, 1902, *Bul.* 82, pp. 5).—Analyses are reported of 18 samples examined especially for the detection of alcohol and added preservatives.

The composition of fresh and canned pineapples, L. S. MUNSON and L. M. Tolman (*Jour. Amer. Chem. Soc.*, 25 (1903), No. 3, pp. 272-280).—Previously noted (*E. S. R.*, 14, p. 522).

The chemical composition of food preservatives, J. B. WEEMS and I. J. MEAD (*Iowa Sta. Bul.* 67, pp. 259-265).—An examination was made of a number of different brands of Preservaline, recommended by the manufacturers for preserving different kinds of food, which led to the following deductions:

"The various brands of preservatives are composed of common substances such as boric acid and borax, salt, formaldehyde, etc., which can be prepared at a cost less than that charged for these substances under some other name. The claims made by those selling mixtures for preserving food under meaningless terms are of no value and are misleading. With proper care and by hygienic conditions connected with the production of dairy and food products, preservatives are unnecessary.

"The use of food preservatives are prohibited by many States, and the use of such substances under some other name does not excuse the person using them."

Preservatives and coloring matters in food, C. E. CASSAL (*British Food Jour.*, 4 (1902), Nos. 40, pp. 76-78; 41, pp. 99, 100; 42, pp. 124, 125; 43, pp. 140-148).—The characteristics, effects, and legal aspects of the use of different preservatives and coloring matters are discussed, work done by the author being cited.

Chemical studies of paprika, W. SZIGETI (*Ztschr. Landw. Versuchs. Oesterr.*, 5 (1902), No. 10, pp. 1208-1222).—Physical and chemical studies of paprika oil were undertaken with the special object of furnishing means for the detection of adulterating powdered paprika with oil.

Concerning organic compounds of sulphurous acid in foods, W. KERP (*Ztschr. Untersuch. Nahr. u. Genussm.*, 6 (1903), No. 2, pp. 66-68).—A preliminary note on experiments, showing, it is claimed, that when fruits are bleached with sulphur fumes some sulphurous acid is retained in chemical combination.

Investigations on the nutrition of man in the United States, P. O. SMOLENSKI (*Hyg. Rundschau*, 12 (1902), Nos. 18, pp. 905-932; 19, pp. 973-1006; 22, pp. 1133-1157).—In this article, a translation of one previously published by the author in Russian (*E. S. R.*, 14, p. 69), the nutrition investigations which have been carried on under the auspices of the U. S. Department of Agriculture are described in detail.

The dietary of families of Danish laborers, M. RUBIN (*Consommation de familles d'ouvriers Danois. Rome: J. Bertero & Co.*, 1902, pp. 84).—This paper, which is an extract from *Bulletin de l'Institut international de statistique* (vol. 13, No. 3), gives statistics of the sums annually expended by the families of Danish laborers for different articles of diet, as well as of other family expenses, the data being discussed with special reference to the family dietary.

Filipino ration, emergency ration, etc., J. F. WESTON (*Com. Gen. Subsist. U. S. Army, Rpt.* 1902, pp. 26, 27).—The kinds and amounts of different foods making

up the ration of enlisted men of the Philippine Scouts, when on garrison or field service, are noted and other topics connected with the army ration are treated of. It is stated that the emergency ration, discussed at length in a previous publication,^a has been quite generally used in the Philippines, "though it has not proved wholly a success, but experiments are still in progress, and it is expected that in due time a ration of this character will be evolved which will prove satisfactory in every respect."

What one eats in the Philippines, A. W. GREELEY (*Ladies' Home Jour.*, 20 (1903), No. 4, p. 10).—The author briefly discusses the fruits, vegetables, meats, and fish used in different localities in the Philippines, methods of preparation, diet of natives and foreigners, and related topics.

Alcohol and muscular energy, L. SCHNYDER (*Arch. Physiol. [Pflüger]*, 99 (1903), No. 9-10, pp. 451-484, figs. 7).—In the experiments reported muscular work was performed with a Dubois ergograph, which is a modification of the apparatus devised by Mosso. The following conclusions were reached: Small doses of alcohol have a favorable effect upon muscular action when taken fasting and when the bodily strength is, to some extent, reduced as a result of individual condition. The favorable effect is less than that of a food of like energy value. At the same time the alcohol hinders the action of the nervous system, the amount being proportional to the physiological condition of the subject. When sufficient energy is provided by the food, alcohol has no value, but on the other hand its effect on the nervous system is more pronounced and results in a diminution of muscular power.

A physiological study of nucleic acid, L. B. MENDEL, F. B. UNDERHILL, and B. WHITE (*Amer. Jour. Physiol.*, 8 (1903), No. 5, pp. 377-403, dgm. 1).—In this article, which has to do with the chemistry, physiological action, and fat in the body of nucleic acid, the authors review at length the previous investigations on the subject, and report experiments with lower animals and with man, the work being summarized as follows:

"The more important observations recorded in this paper indicate that the vegetable nucleic acid obtained from the wheat embryo resembles, in its physiological effects, the guanylic acid of the pancreas. Introduced in sufficient doses into the circulation, it may produce a fall in arterial pressure; a change in the coagulability of the blood; an increase in the flow of lymph and a change in its composition; and perhaps, also, a degree of immunity toward subsequent injections.

"The ingestion of nucleic acid is followed in man by an increased output of uric acid, and in the dog by the excretion of allantoin. These products correspond in either case to only a portion of the purin radicals introduced. In animals, allantoin excretion was also observed after the introduction of vegetable nucleic acids into the body per rectum, intravenously, intraperitoneally, and subcutaneously. Some features of intermediary purin-metabolism are discussed."

Notes on the "protagon" of the brain, W. W. LESEM and W. J. GIES (*Amer. Jour. Physiol.*, 8 (1902), No. 3, pp. 183-196).—Chemical studies, including elementary analyses, led the authors to the conclusion that "the protagon of the brain is a mixture of substances, not a chemical individual, [and that] the mixture called protagon does not contain the bulk of the phosphorized organic substance of the brain."

Camp fires in the wilderness, E. W. BURT (*Boston: National Sportsman Press*, 1902, pp. 164, pls. 23).—In addition to other matters pertaining to camps and camping, the author discusses food and its preparation in camp, giving a number of recipes and an estimate of the kinds and amounts of food sufficient for 3 men on a 2 weeks' camping trip.

How I live without cooking, W. T. LARNED (*Ladies' Home Jour.*, 20 (1903), No. 3, p. 18).—The author states that for some 2 years he has lived almost exclusively on a diet of raw cereals, fruits, nuts, vegetables and milk, butter and eggs, with the addi-

tion of some raw meat during a part of the time, the average cost of the diet being about 30 cents per day.

Yeast and its household use, F. C. HARRISON (*Ontario Agr. Col. and Expt. Farm Bul. 118, pp. 16, figs. 6*).—As a result of experiments made to determine the rapidity of fermentation of yeast procured from a number of sources, it was found that “there were three which gave a much more rapid fermentation than any of the others, and which were considered to be equal. One of these was from a distillery, one from a compressed yeast (sold for bread making and ordinarily produced at a distillery), and the third from a home-grown yeast which had been started with a compressed distillery yeast. The beer yeasts in several instances gave better results than yeasts sold specially for bread making. Some of the latter gave very poor results indeed, showing that sufficient care had not been taken when starting the growth of the yeast at the factory to obtain one which was well adapted to bread making. The experiments show the superiority of distillery yeasts over brewery yeasts for the fermentation of flour. They seem to act upon the starch of the flour more energetically than do the beer yeasts. In experiments made on mixtures of flour and water in fermentation tubes, the distillery yeasts always produced considerably more gas than did the other kinds; they also produced the gas more quickly.”

The general subjects of yeasts and their uses are discussed and suggestions are given for the household preparation of yeast. The comparative merits of different sorts of bread are also spoken of briefly.

ANIMAL PRODUCTION.

The principles of animal nutrition, H. P. ARMSBY (*New York: John Wiley & Sons, 1903, pp. VIII+614*).—This volume, which in substance represents the author's lectures before the Graduate Summer School of Agriculture at the Ohio State University in 1902, summarizes in systematic form the valuable information which has accumulated regarding the principles of animal nutrition, especially from the standpoint of energy relations and their bearing upon the nutrition of farm animals. The main divisions of the volume deal with the income and expenditure of matter and of energy. Under the former subject the author discusses food, metabolism, methods of investigation, fasting metabolism, the relations of metabolism to food supply, and the influence of muscular exertion upon metabolism. In the section devoted to energy the subjects are force and energy, methods of investigation, the conservation of energy in the animal body, food as a source of energy—metabolizable energy, internal work, net available energy—maintenance, and the utilization of energy. In every case the author has discussed in detail the results of experiments published by numerous writers and summarized them with especial reference to their bearing upon the metabolism of matter and energy.

The most satisfactory terminology for use in discussions concerning the income and outgo of energy is a matter on which opinions differ, and Professor Armsby has proposed the term “metabolizable energy” for that fraction of the energy of the food which can enter into the metabolism of energy in the body. “Metabolizable energy, then,” he states, “may be briefly defined as potential energy of food minus potential energy of excreta, including under excreta, of course, all the wastes of the body, visible and invisible. The method is analogous to that of the determination of digestibility. In both cases it is a calculation by difference, and the result shows simply the maximum amount of matter or of energy put at the disposal of the organism without affording any clue to the use made of it by the latter—that is, to its availability in the more restricted sense.”

The appendix includes tables showing the metabolizable energy of coarse fodders and other feeds, and the energy expended by a horse in locomotion and drawing a load under different conditions. A detailed index adds to the value of the volume, which summarizes in a form very useful for advanced students the experiments and conclusions of the leading modern investigators, and the theories and the deductions which may be drawn from the large amount of valuable experimental evidence.

The exact calculation of balanced rations, J. T. WILLARD (*Kansas Sta. Bul.* 115, pp. 97-146).—According to the author, "the bulletin maintains, and the method of calculation is based upon the fact, that, reduced to a final analysis, the balancing of a ration consists in balancing the feeds used in it two by two. In this pairing, any one of the feeds may be used more than once, and the several quantities of a feed so used are finally added together to obtain the total sum. Recognition of the compound nature of this sum is essential to an understanding of the theory of the balancing of rations."

The method of calculating balanced rations, on the basis of the protein, fat, and carbohydrate content, is described and a method suggested, regarded as ample for practical requirements, which takes into account only protein and nonnitrogenous constituents. In addition a table is given which shows the relative amounts of a number of feeds, arranged in pairs, which must be used to approximate the nutritive ratios called for by the commonly accepted feeding standards. Figures are given for 14 different ratios. In the author's opinion "the mixtures given may in many cases constitute a ration; in others, a ration may be compounded by using, in any proportion desired, any of the various mixtures having the same nutritive ratio."

Stock raising (*Bul. Maine Dept. Agr.*, 1 (1902), No. 3, pp. 83-118).—A number of articles by different authors on problems connected with stock feeding are included, as well as data recording local crop conditions, based on statements received from a number of correspondents in different parts of the State.

Concerning the estimation of starch and the digestibility of carbohydrates, S. WEISER and A. ZAITSCHEK (*Arch. Physiol. [Pflüger]*, 93 (1902), No. 3-4, pp. 98-127).—The authors studied the estimation of starch in the presence of pentosan, the estimation of carbohydrates in feces, and the digestibility of the different constituents of the carbohydrate group with different farm animals. Starch in feeding stuffs was estimated by heating the material in autoclaves for 4 hours, inverting with hydrochloric acid, neutralizing and determining the amount of reducing sugars with Fehling's solution. A correction was introduced for the pentosan which was also converted into reducing substances, the amount being learned by determining the amount of furfural-yielding material in a suitable sample after heating in the autoclave and assuming that it had a reducing value equal to that of dextrin. The reducing body the authors consider to be a mixture of arabinose and xylose, and the reducing value was assumed to be the same as that of dextrose, since experiments, reported in detail, show that arabinose had somewhat less and xylose somewhat more reducing power than dextrose, and that these values were not changed by the proportions in which the materials were present.

The authors' experiments led to the conclusion that starch in the feces of mammalia and birds can be estimated by the same methods as are used in the case of feeding stuffs, that is, without the addition of phosphotungstic acid or other precipitant. Using the methods described, analyses are reported of the feeding stuffs used in their experiments with different animals (meadow hay, broom corn seed, oats, maize, and fodder beets), as well as determinations of the carbohydrates in the feces of the animals.

The experiments reported were made with a horse, a duck, and steers, pigs, sheep, and geese. The rations consisted of different mixtures of the feeding stuffs enumerated and the results showed the digestibility of the different members of the carbo-

hydrate group, especially crude fiber, starch, and pentosans. The average coefficients of digestibility obtained with the different classes of farm animals follow:

Average coefficients of digestibility of carbon

	Cellulose.	Starch.	Pentosans.	Undetermined material.	Total nitrogen-free extract.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Steer	56.0	96.6	63.4	44.8	74.7
Sheep	55.1	89.4	53.6	32.9	68.5
Horse	40.6	93.1	45.5	42.3	71.1
Swine	22.8	98.3	47.9	28.0	85.6
Poultry		87.9	23.9		

The authors conclude that determining the coefficients of digestibility of the constituents of the nitrogen-free group shows much more clearly the true digestibility of this portion of feeding stuffs than the method commonly followed.

Corn as a stock food. H. J. WATERS (*Missouri Sta. Circ. of Information 11, pp. 42, figs. 4*).—The chemistry of corn and the importance of the corn crop for farm animals, including poultry, are discussed. The results of several experiments carried on at the station on the possibility of increasing the value of corn stover by combining some such material as clover, cowpea hay, or alfalfa, and the comparative value of such a mixture and timothy hay are briefly reported. It was found that yearling steers, on timothy hay alone, consumed 21.7 lbs. feed per day per 1,000 lbs. live weight as compared with 25.2 lbs. whole-corn stover and clover hay 1:1. The gains during the feeding period, 74 days, on the 2 rations were 30.8 and 58.4 lbs., respectively. Similar results were obtained when shelled corn was added to the ration. Four yearling steers fed 4 lbs. of corn per day, in addition to timothy hay, made an average daily gain of 0.64 lb. per head for 104 days. On a ration of corn, clover hay, and corn stover an average daily gain of a similar lot was 0.88 lb.

In a second test, under practically the same conditions, 4 steers fed 6 lbs. of corn per head daily, in addition to timothy hay, made an average daily gain of 1 lb. per head for 80 days, while steers fed the same amount of corn in addition to clover and corn stover gained 1.35 lbs.

During a period of 119 days 4 steers on a full feed of shelled corn with timothy hay made an average daily gain of 1.69 lbs., as compared with 1.94 lbs. made by a similar lot in the same time on a corn, clover hay, and corn stover ration. In a similar test, also made with 2 lots of 4 steers each, covering 105 days, the relative gains were 1.97 and 2.85 lbs.

"Thus it appears in every case, whether fed without grain, with a small allowance of grain, or on full feed, whether with yearlings or aged cattle, a combination of corn stover and clover hay proved superior to timothy hay. In other words, the farmer is able by this means to make the stover serve every purpose, in cattle feeding at least, for which timothy is now used. Under these circumstances it is fair to say that timothy and stover have at least equal feeding values. It is quite probable that where such hays as clover, alfalfa, and cowpeas are not available, a small quantity of cotton-seed meal, linseed meal, gluten meal, or bran may serve the same purpose and accomplish the same result, viz, of enabling the feeder to use his stover to the best possible advantage, and as a complete substitute for timothy. It is needless to say that the accomplishment of this result would be attended by an immense increase in the net returns from the corn crop."

Two tests on the comparative merits of shredded or cut stover as compared with whole-corn stover are also reported. On an average yearling steers ate 25.8 lbs. of whole stover per head daily as compared with 20.6 lbs. of the shredded stover. Considering the tests as a whole, there was no gain or loss on the former ration

while there was a loss of 11.6 lbs. on the latter. Nearly as much of the shredded stover as of the whole was left uneaten, the percentage being 36 for the former and 40.6 for the latter.

"In no case do the steers do as well on the shredded as on the whole stover, and in every instance the whole stover was more palatable. This appears to be accounted for by the fact that when the material is offered in its natural condition the animals have an opportunity to select the portions they prefer and discard the coarser and unpalatable parts, whereas in the case of the shredded stover the blades, husks, etc., are so intermingled that no opportunity is offered for selection.

"It must be conceded that when the corn can be husked and the stover shredded at practically the usual cost of husking the corn, the practice must commend itself to every farmer on account of the greater convenience with which the material may be fed and the preservation of the material in the mow or rick. But to be at the expense of shredding the stover after the corn is husked would in all probability be unprofitable."

Other problems connected with corn feeding are also discussed on the basis of experiments at the Missouri and other stations.

Some lessons from cattle-feeding experiments, F. B. MUMFORD (*Bul. Missouri State Bd. Agr.*, 2 (1902), No. 9, pp. 3-10).—The cost of producing a pound of beef, the conditions influencing economy of gain, the value of nitrogenous coarse fodders, pasturage, winter and summer feeding, and related topics are discussed with especial reference to the work of the Missouri and other stations. Comparing different kinds of coarse fodder the Missouri Station found that with a lot of 4 steers on a full feed of shelled corn and timothy hay the average daily gain was 1.69 lbs. for 100 days. In the same time with a similar lot on corn and cowpeas the average daily gain was 2.64 lbs.

Environment and heredity, two great factors in cattle breeding, B. GABBERT (*Missouri State Bd. Agr. Mo. Bul.*, 2 (1902), No. 9, pp. 13-17).—The general principles of the subject are summarized.

Concerning the metabolism of ruminants, J. HUTH (*Inaug. Diss., Univ. Bonn*, 1902, pp. 82).—A 2-year-old sheep was the subject of experiments which are reported in detail. The feed and excretory products were analyzed and the respiratory quotient was determined while the animal was fasting, feeding, and during the period in which the digestive processes were active. In one of the tests the ration consisted of meadow hay, in another of green alfalfa, and in the third of meadow hay and tropon by-products, salt and water being given with the first and third rations in addition. The digestibility of these rations is reported. According to the author the amount of oxygen absorbed from the air and the carbon dioxide produced is greater when feed is consumed and during the period in which the processes of digestion are active than when the animal is fasting. From the data recorded the energy balance is calculated and the conclusion drawn that with ruminants there is no difference in the amount of labor required for chewing and digesting hay and green feed.

Sheep feeding in Montana, R. S. SHAW (*Montana Sta. Bul.* 39, pp. 15).—The importance of the sheep feeding industry under local conditions is urged. Methods of feeding are described, the results of the station experiments in this direction being briefly noted.

Report of an experiment for ascertaining the influence of various manures upon the production of mutton, W. ASHCROFT (*Jour. Bath and West and Southern Counties Soc. [England]*, 4. ser., 7 (1901-2), pp. 182, 183).—Brief notes are given of a test in which sheep were pastured on plats manured in different ways.

Thrift, the great essential in sheep feeding, J. ZIEGLER (*Missouri State Bd. Agr. Mo. Bul.*, 2 (1902), No. 9, pp. 18-21).—Sheep feeding is discussed with special reference to the author's experience.

Pork production in Montana, R. S. SHAW (*Montana Sta. Bul.* 37, pp. 10, pls. 2).—Methods of pig feeding are discussed with special reference to Montana conditions, earlier work at the station being quoted (E. S. R., 14, p. 74).

The importance of sugar beets supplementing the grain ration was tested with 2 lots, each containing 4 pigs. The lot fed grain gained on an average only 1.58 lbs. each daily during 50 days, the cost of a pound of gain being 4.6 cents. The lot receiving grain with sugar beets in addition gained on an average 1.64 lbs. daily, the cost of a pound of gain being 3.8 cents. The former were given a heavy grain ration of 9.11 lbs. per day and the latter a ration of 6.65 lbs. of grain and 4.58 lbs. sugar beets per head per day. It was calculated that in this test there was a net profit of \$14.12. An earlier test is also noted (E. S. R., 13, p. 274).

Experiments on the effect of time of drinking water upon the digestibility of feed, F. TANGL (*Landw. Vers. Stat.*, 57 (1902), No. 5-6, pp. 329-358, 381-404).—Using 3 horses as subjects the author studied the effect upon digestibility of drinking water before eating, after eating, and during a meal—that is, immediately after the grain portion of a ration and immediately before the coarse fodder. In most of the experiments the horses were fed oats and hay; in some cases hay alone, and in others oats and maize with chopped straw and hay. Experimental data are recorded in full. So far as could be observed the time of drinking did not have an effect upon the digestibility of a ration of grain and coarse feed. It seemed probable that when hay only was fed there was a slight advantage in watering after feeding. The time of drinking exercised a marked effect on the amount of water consumed and upon the amount of water excreted. The horses drank the greatest amount of water when it was given after feeding, and the least when it was supplied before feeding. This was especially noticeable in the morning, when water was sometimes refused if offered before feeding. The excretion of urine was directly proportional to the amount of water consumed. When it is desired to increase the excretion, the author recommends water after feeding. The method of watering had no effect upon the amount or qualitative composition of the feces. Body weight varied with the amount of water consumed. Though the methods of watering tested were regarded as equally good, circumstances may, in the author's opinion, make it necessary to adopt one or the other. Thus, after severe exertion water should be supplied before the feed. It is said that it is not desirable to change unnecessarily from one method of watering to another, as some animals do not appear to be altogether indifferent to such changes. It was found that whenever a change was made from watering after feeding to watering before, the appetite fell off for some days and the ration was not as readily eaten as formerly. A similar effect was not observed when the change was from watering before to watering after feeding, or from watering after to watering during meals, or when the change was in the opposite direction to the last. The author believes it possible that the method of watering before feeding, until the animal becomes accustomed to it, produces a certain feeling of satiety.

Contribution to the subject of the metabolism of inorganic material by horses, F. TANGL (*Landw. Vers. Stat.*, 57 (1902), No. 5-6, pp. 367-380).—Two experiments, each made with 2 horses, are reported in which the balance of income and outgo of nitrogen, phosphorus, calcium, and magnesium was determined. In the first experiment the daily ration of each horse consisted of 8 kg. of hay, one horse drinking 19.6 kg. of water and the other 26.5 kg. In the second test the daily rations of the horses consisted of 5 kg. hay and 4 kg. of oats, the amount of water consumed by each being 17.3 kg. and 22 kg., respectively. During the 5 days covered by the first test the horses lost on an average 0.5 kg. and 0.63 kg., respectively, in body weight, and in the second test, which covered 6 days, there were corresponding gains of 0.45 kg. and 0.72 kg. The results of the experiments are shown in the following table:

Income and outgo of inorganic material—Experiments with horses.

	Horse No. 3.				Horse No. 4.			
	Nitro- gen.	Phos- phorus.	Cal- cium.	Magne- sium.	Nitro- gen.	Phos- phorus.	Cal- cium.	Magne- sium.

According to the author, the experiments show that there is a parallelism between the metabolism of nitrogen and phosphorus, and that even in the case of adult animals the amount of calcium retained in the body is not necessarily proportional to the amount digested. So far as could be observed the amount of water taken with the feed had no effect upon the metabolism or digestibility of the mineral constituents studied.

Experiments with poultry, O. M. WATSON (*South Carolina Sta. Bul. 74, pp. 6*).—Since one of the drawbacks to successful turkey raising is the loss of eggs due to turkeys making their nests a long distance from home, the possibility of inducing them to lay when confined in runs was studied with 2 lots, each containing 2 hens and 1 male bird. Bronze birds 2 years old in the one case and 3-year-old White Hollands in the other. Each lot was confined in a run 80 by 100 ft., 2 nests covered at the top to keep out the rain and partially hidden behind some brush being provided in each case. The turkeys were fed in the morning a mash of wheat bran and corn meal 1:1, with whole corn and wheat on alternate nights. Twice a week they were given ground bone and meat scrap and always had access to oyster shells. The Bronze turkeys laid 42 eggs from March 26 to April 22 and the White Holland 36 eggs from March 24 to May 4. At the end of the tenth day examination showed that 38 of the former and 27 of the latter eggs were fertile. Twenty-seven of the Bronze turkey eggs and 16 of the White Holland eggs hatched. During incubation the Bronze hens broke 4 eggs and the White Holland 6, all of which were fertile. It is stated that all the eggs which failed to hatch were laid during the first 2 weeks of the test.

Two tests are briefly reported on the most satisfactory breeds of chickens for broilers. In both tests 10 chickens of each of the following breeds and crosses were included: Barred Plymouth Rock, Silver Laced Wyandotte, Indian Game, Indian Game and Pit Game crossed with Barred Plymouth Rocks, and Barred Plymouth Rock and Silver Laced Wyandotte crossed with common hens. The feeding period covered 12 weeks, all the chickens being fed for the first week after they were hatched a bread made of corn meal and wheat bran and buttermilk; during the second week bread, beef scrap, and German millet; and from the third week until the close of the test bread, beef scrap, cracked corn, and cracked wheat with milk or buttermilk once a day in addition to green feed (rye, lettuce, rape, and kale).

In the first test the smallest gains were made by the Silver Laced Wyandotte crosses, weighing 40 oz. per chicken at the end of the twelfth week. The greatest gains were made by the Indian Game-Barred Plymouth Rocks, weighing 46 oz. In the second test the smallest gains were also made by the cross-bred Silver Laced Wyandottes, these chickens weighing 41 oz. at the close of the trial. The greatest gains were made by the Pit Game-Barred Plymouth Rocks, weighing 46 oz. According to the author "The Wyandotte, Indian Game and Plymouth Rock cross and Pit Game and Plymouth Rock cross showed a plump breast. The Pit Game and

Plymouth Rock cross, the Plymouth Rock and common cross, and the Wyandotte had most feathers. The Indian Game had very few feathers but was plump. The cost of feed per chicken to 8 weeks was 7.5 cts. The cost of feed per chicken to 12 weeks was 12 cts. The cost for feed when this experiment was made was unusually high. No account of green food given was kept."

Brief statements are made regarding remedies for some common poultry diseases.

Poultry experiments, J. H. STEWART and H. ATWOOD (*West Virginia Sta. Bul.* 83, pp. 443-465, pls. 3).—Beef scraps, ground fresh meat and bone, and milk albumen as sources of protein for laying hens were compared with 3 lots each containing 10 White Leghorn pullets, 10 two-year-old hens, and 2 cocks. All the lots were fed corn and oats, whole and ground, wheat and wheat bran. In addition lot 1 was fed the beef scraps, lot 2 the milk albumen, and lot 3 the ground fresh meat and bone during the first period of the test (120 days). During the second period, which was of equal duration, the grain ration was practically the same as before, but the animal feeds were reversed, lot 1 receiving the fresh meat and bone, lot 2 the beef scraps, and lot 3 the milk albumen. Throughout the test an attempt was made to feed practically the same amount of protein to each lot, but at no time were the fowls fed heavily.

At the beginning of the trial the hens weighed about 3.2 lbs. and the cocks not far from 4 lbs. During the first period slight gains were made. During the second period there was a small loss in nearly every case. In the first period the fowls receiving beef scraps laid 386 eggs, those fed milk albumen 228 eggs, and those fed fresh meat and bone 279 eggs. In the second period 987 eggs were produced on the beef scrap ration, 935 on milk albumen, and 947 on fresh meat and bone. The cost of feed per dozen eggs in the first period on the 3 rations was 17, 30.4, and 23.1 cts., respectively. In the second period the cost was 6.6, 7.3, and 6.8 cts., respectively.

"More eggs were laid by the fowls when fed beef scraps than when they received either ground fresh meat and bone or milk albumen. The health of the fowls remained uniformly good throughout the test, and the low egg yield was due partly to the fact that the houses in which the fowls were kept were not constructed warm enough for economical egg production during the winter, and partially to the fact that the fowls were not fed heavily at any time for egg production, as many of the eggs were incubated, and strong, vigorous chicks were desired." There was no material difference in the fertility of the eggs from the different lots.

In a test covering 2 periods of 60 days each, made with 5 lots, ground grain was compared with whole grain for the morning and evening ration of laying hens. Lots 1, 2, and 3 were composed of 20 White Leghorn hens and 2 cocks nearly 1 year old at the beginning of the trial. Lots 4 and 5 each contained 20 White Leghorn hens and 2 cocks about 4 years old. The grain ration consisted of corn and oats, unground and ground, the latter being made into a mash with water. Some dry beef scraps were given to the chickens receiving whole grain, and were mixed with the mash of the other lots. During the first period lot 1 received whole grain scattered in the litter in the morning, and mash at night; lots 2 and 4 were fed mash in the morning and whole grain at night, and lots 3 and 5 were fed entirely upon whole grain. The younger fowls weighed about 3 lbs. at the beginning of the trial and the older fowls not far from 3.33 lbs. At the close of this period all the lots had lost a little in weight. The greatest number of eggs, 674, were laid by lot 2 (young fowls fed a mash in the morning), and the smallest number, 519, by lot 3 (young fowls fed whole grain). The total feed eaten per lot ranged from 269 lbs. with lot 1 to 274 lbs. with lots 4 and 5. The cost of feed per dozen eggs ranged from 5.4 cts. with lot 2 to 7 cts. with lot 3.

In the second period the rations were reversed in such a way that lot 2 was fed whole grain in the morning and mash at night, lots 3 and 5 a mash in the morning and whole grain at night, and lots 1 and 4 were given whole grain. Lot 2 neither

gained nor lost in weight. The chickens in the other lots gained on an average from 0.02 lb. in the case of lot 4 to 0.16 lb. in the case of lot 1. The total feed eaten by lot 2 was 216 lbs. and by the other lots 215 lbs. each. The eggs laid ranged from 472 with lot 4 (fed whole grain) to 549 eggs with lot 2 (fed whole grain in the morning and mash at night). The cost of feed per dozen eggs ranged from 5.2 cts. with lot 2 to 6.1 cts. with lot 4. Some of the authors' conclusions follow:

"In this experiment the egg production was practically the same when the mash was fed in the morning as when fed at night. With both young and old fowls better results were obtained when about one-third of the grain ration was fed ground and moistened than when all of the grain was fed whole and scattered in the litter. During the test the average food-cost of the eggs laid by the young fowls was 5.8 cts. per dozen, while with the older hens the cost was 6.3 cts. In this connection it should be remembered, however, that these fowls had a very restricted range, and that all of the food that they received was charged to them at full market rates."

In continuation of previous work (E. S. R., 13, p. 276) 2 tests were undertaken to determine the importance of keeping hens warm at night by means of curtains surrounding their perches, 2 lots, each containing 20 White Leghorn pullets and 2 cockerels, being used. Both lots were given a mash of ground feed each morning to which was added a small quantity of beef scraps, and at night were fed whole grain scattered in the litter which covered the floors. During the coldest nights of the test, when the temperature of the houses would fall nearly to the freezing point, lot 1 was protected at night with curtains. The average weight at the beginning of the trial was 2.72 lbs. At the close of the trial, which covered 120 days, the average weight was 3.2 lbs. Similar values for lot 2 were 2.66 lbs. and 3.14 lbs. The total egg production for the 2 lots was 334 and 358 eggs, respectively. The cost of feed per dozen eggs was 16.8 cts. and 15.6 cts. Practically the same amount of feed was eaten by the 2 lots, namely, 120 lbs. of corn, 125 lbs. of wheat, 83 lbs. of oats, 23 lbs. of beef scraps, and 28 lbs. each of corn meal, brown middlings, and ground oats.

The second test was made with 2 lots each containing 15 Barred Plymouth Rock pullets and 1 cock. The space shut in by curtains was larger than before, being 90 cu. ft., or about 5.5 cu. ft. per fowl. The test began November 1 and covered 120 days, during which lot 1 (protected at night) laid 244 eggs and lot 2 laid 247 eggs. According to the authors, "during 18 days, beginning January 4, the temperature of the roosting places was taken at night by means of maximum and minimum thermometers. The average of the lowest temperatures for the cold house was 35.5° and within the curtains 41.5°. The results of both of these tests are unfavorable to the use of curtains in this climate."

The Van Dreser method of producing an early and uniform molting was also studied. In brief, this method consists in withholding feed wholly or in part for a few days to stop egg production and reduce the weight of the fowls, and then feeding heavily a ration suitable for the formation of feathers and the general upbuilding of the system. Four lots of 20 hens and 2 cocks each about 2 years old were included in the trial, 2 of the lots being Rhode Island Reds and 2 White Leghorns. One lot of Rhode Island Reds (lot 1) and 1 lot of White Leghorns (lot 3) were fed throughout the test an ordinary ration of grain mash, beef scraps, corn, wheat, and oats. The remaining lots received no feed for 13 days, except what they could pick up in their runs, which had been sown with oats in the spring. The runs were 100 feet long and 15 feet wide, and it is stated that nearly all the oats had been picked from the heads before the beginning of the test. Beginning with the third week these lots were fed a full ration similar to that of lots 1 and 3. During the first 30 days after the beginning of the trial lots 1 and 3 (fed continuously) laid 75 and 172 eggs, respectively. The other two lots laid, respectively, 17 and 25 eggs, ceasing to lay entirely on the seventh day. The authors state that 30 days after the test began the lot of Rhode Island Reds (given no feed for 13 days) "had practically a complete coat of new feathers, had begun to lay, and

within a week from that time one-half of the hens were laying regularly, while the other lot of Rhode Island Reds were just beginning to molt and the egg production had dropped down to 2 or 3 eggs per day. Both lots of White Leghorns were a trifle slower in molting than the Rhode Island Reds, but otherwise the treatment affected them in a similar way."

For 10 days the dropping boards in the 2 White Leghorn houses were not cleaned. There were comparatively few feathers in the droppings from the lot fed continuously, while a very large number were found in the droppings of the fowls fed by the Van Dreser method. According to the authors' summary—

"Mature hens which are fed very sparingly for about 2 weeks and then receive a rich nitrogenous ration molt more rapidly and with more uniformity, and enter the cold weather of winter in better condition, than similar fowls fed continually during the molting period on an egg producing ration."

Commercial feeding stuffs in the Connecticut market, E. H. JENKINS ET AL. (*Connecticut State Sta. Bul. 141, pp. 60*).—According to the provisions of the State feeding stuff law, analyses are reported of a number of samples of cotton-seed meal; linseed meal, old and new process; bran and middlings from winter and spring wheat; mixed feed from spring and winter wheat, and unclassified; corn meal, gluten meals and feeds, hominy feeds; rye bran, rye feed; malt sprouts, brewers' grains; ground oats, oat feed; buckwheat middlings and hulls; peanut bran, broken peanuts, distillers' grains, and a number of miscellaneous mixed feeds; proprietary feeds; cereal breakfast food by-products; poultry feeds; damaged breakfast foods (offered for sale as cattle feed), and calf meal. According to the authors—

"The composition of most of the feeds which have guaranties is in substantial agreement with these guaranties. The only evidence of deliberate fraud in the feed market which is shown by the analyses is the mixing of finely ground corn-cob or corn bran with mixed wheat feed, and selling this mixture in packages which do not bear the name of the manufacturers nor any statement giving the composition of the mixture."

The digestibility of feeding stuffs and some other general topics are discussed.

Slaughtering and meat packing, H. C. McCARTY (*Twelfth Census United States, Census Bul. 217, pp. 45*).—Statistics are reported of the geographical distribution, the condition at the present time, and the growth of the slaughtering and packing industry. The reports show a capital of \$189,198,264 invested, and an annual value of products of \$785,562,433.

Wool manufactures, W. J. BATTISON (*Twelfth Census United States, Census Bul. 236, pp. 125*).—Statistics are given showing the present condition of wool-manufacturing industries, the amount of imports and exports, the geographical distribution of the mills, the proportional amount of different manufactured products, and related topics. The annual value of the manufactured products is estimated at \$392,473,050.

DAIRY FARMING—DAIRYING.

Experiments with dairy herd, A. L. HAECKER (*Nebraska Sta. Bul. 76, pp. 21, figs. 6*).—*The herd record* (pp. 3-13).—During the 5 years from 1897 to 1901 the dairy herd comprised from 7 to 14 cows each year. The annual production of each cow is given. The average yields of milk, fat, and estimated butter for the 52 lactation periods reported were, respectively, 5,833.17, 270.7, and 315.82 lbs. One cow, a grade Jersey, produced on an average during the 5 years 7,377.68 lbs. of milk and 316.25 lbs. of fat, while another cow of similar breeding but different in form produced only 1,278.76 lbs. of milk and 52.77 lbs. of fat during the one year in the herd.

Ration tests for dairy cows (pp. 14-18).—Twelve cows were divided into 2 equal lots and fed experimentally for 2 periods of 6 weeks each. Alfalfa hay was fed ad libitum to lot 1 during the first period and lot 2 during the second period, and wild grass

hay was fed in the same manner during the alternate periods. Both lots were fed a uniform ration of grain and beets. On alfalfa hay the 12 cows produced 9,862.74 lbs. of milk and 511.47 lbs. of butter, and on wild hay 9,722.49 lbs. of milk and 502.07 lbs. of butter, showing a difference of 140.25 lbs. of milk and 9.40 lbs. of butter in favor of alfalfa.

A comparative test was also made of corn silage and sugar beets fed in equal amounts in connection with a uniform ration of alfalfa hay and grain. The test was made with 2 lots of 5 cows each and lasted 5 weeks. The difference in production of the 2 lots for the 5 weeks previous to the test when both were fed silage was 129.2 lbs. of milk and 5.7 lbs. of butter, and the difference during the 5 weeks of the test, when one lot was fed silage and the other lot sugar beets, was 221.4 lbs. of milk and 10 lbs. of butter, the results being in favor of silage. "While corn silage gave slightly better results than sugar beets when fed to dairy cows, the difference was so small that it is safe to say they are quite equal in feeding value."

The best week in a cow's lactation period (pp. 19-21).—To obtain information on this subject 155 records from the Minnesota Station and 84 from the Nebraska Station were compiled. The results show that the greatest number of cows made their best yield of milk during the third week and their best yield of butter during the second week, the difference between the second and third weeks not being very great. The first week was calculated as beginning 4 days after calving.

Feeding the dairy cow, C. H. ECKLES (*Missouri Sta. Bul.* 58, pp. 53-72).—Based upon the results of practical feeding by dairymen and of scientific experiments, the author offers suggestions for feeding adapted to Missouri conditions. The subjects touched upon in the discussion include turning on pasture in the spring, grain feeding on pasture, providing for periods of short pasture, reasons for feeding balanced rations, buying concentrated feeds, grinding feed, computing rations, and the use of feeding standards. Several suitable rations are suggested.

Butter record of the Buckhold herd, H. WATNY (*Jour. Bd. Agr. [London]*, 9 (1902), No. 3, pp. 312-319).—The herd comprised 46 cows during the year ended September 30, 1902. The average annual production of 29 cows remaining in the herd for the whole year was 450.8 lbs. of butter per cow.

Milking and butter test trials, E. MATHEWS (*Jour. Bd. Agr. [London]*, 9 (1902), No. 3, pp. 297-306).—This is a brief account of milking trials which have been conducted in England during the last 25 years, and of butter test trials first held in 1886, with a discussion of some of the results obtained.

On the influence of feeding on the composition of the fat of milk, B. SJÖLEMA (*Proc. Soc. Sci., Koninkl. Akad. Wetensch. Amsterdam*, 4 (1901-2), pp. 746-756, pl. 1).—The author studied the influence of feeding sugar-beet tops, sugar, and molasses upon the index of refraction and the content of volatile fatty acids of the butter fat. The feeding of sugar-beet tops as tested with 4 cows on pasture during one month apparently caused an increase of about 8 in the average Reichert-Wollny number and a decrease of about 6 in the refraction number of the butter fat. The fat content of the milk was somewhat increased. In another test made with 3 cows in the stable and lasting about 1 month, raw sugar in daily amounts varying from 0.4 to 2 kg. was estimated as increasing the Reichert-Wollny number of the butter fat from 2 cows 4.7 and 5.95, respectively, as compared with the Reichert-Wollny number of the butter fat from the control animal. In a similar test with molasses and sugar the increase in the Reichert-Wollny number was nearly as marked, the conclusion being drawn from the last 2 experiments that sugar exercises a considerable influence on the increase of the volatile fatty acids in butter fat.

On the composition of cows' milk, H. C. SHERMAN (*Jour. Amer. Chem. Soc.*, 25 (1903), No. 2, pp. 132-142, fig. 1).—The mixed milk of a herd of about 600 pure-bred and grade Jerseys was sampled monthly for the 2 years beginning April, 1900, and analyzed to determine seasonal variations in composition. The samples were all of

the afternoon milk which had been found by frequent tests to contain quite regularly 0.4 per cent more fat and practically the same percentage of solids-not-fat as the morning milk. The percentages of milk sugar and ash were found to remain nearly uniform throughout the year, while the percentages of protein as well as of fat showed a seasonal variation, being higher in the fall and winter than in the spring and summer. A comparison of the results with analyses reported by Van Slyke and by Richmond showed a close agreement, the fat and solids-not-fat having a tendency in each case to rise and fall nearly together. The average composition of the milk for the 2 years was as follows: Total solids 14.71, fat 5.26, solids-not-fat 9.25, protein 3.66, milk sugar 4.84, and ash 0.75 per cent.

During the same period analyses were also made of the milk of individual cows and of certain groups of cows for the purpose of studying variations in other constituents than fat. The average composition of 13 unusually rich samples was as follows: Total solids 18.03, fat 7.76, solids-not-fat 10.27, protein 4.68, milk sugar 4.76, and ash 0.83 per cent. The average composition of 6 samples low in solids-not-fat was as follows: Total solids 11.53, fat 3.90, solids-not-fat 7.63, protein 3.34, milk sugar 3.59, and ash 0.71 per cent. "All of the results obtained accord with the conclusion recently reached by Richmond that any deficiency of solids-not-fat is chiefly due to a deficiency in the milk sugar, while any excess above 9 per cent is chiefly due to an excess of protein."

The following statements are made as regards the relation of protein to fat and to ash: "The data at present available indicate that aside from the seasonal variation already noticed, the percentages of fat and protein tend to rise and fall together, though not to the same extent; that the average relation between the two is approximately expressed by the formula, $\text{protein} = 2 + \frac{1}{3} \text{ fat}$, but that the protein often shows less variation from the average than this formula would imply. . . . In practically all of the samples examined the relation between protein and ash was very nearly that found by Richmond and expressed by the formula, $\text{ash} = 0.36 + 0.11 \text{ protein}$. To agree more exactly with our averages, the formula may be modified to read $\text{ash} = 0.38 + 0.1 \text{ protein}$." The milk sugar showed no tendency to vary with any other constituent.

Pasteurization of milk in bottles with agitation, N. GERBER and P. WIESKE (*Rev. Gén. Lait*, 2 (1903), No. 8, pp. 169-177).—It is stated that a method of pasteurizing milk in bottles subjected to constant shaking has been in practical use by Gerber for 15 years. The advantages of the method are set forth in this article and recent literature relating to standards of pasteurization is reviewed. The method is designated the Gerber method of pasteurization with agitation, and differs from other methods in that during heating and cooling the apparatus containing the bottles of milk is maintained in continuous oscillatory motion. The milk is thereby heated uniformly and the formation of a surface membrane is prevented. By this process, which is considered more rapid and economical than pasteurization without agitation, the milk is said to be left in a better condition as regards color, taste, and odor, and there is less separation of the cream. Bottles containing as much as $\frac{1}{2}$ liter may be used. Until lower temperatures are justified by further investigations the authors favor pasteurization at 65° C. for 30 minutes to 1 hour.

Comparative tests of different methods of distinguishing raw and heated milk, G. MULLIE (*Rev. Gén. Lait*, 2 (1902), Nos. 4, pp. 77-86; 5, pp. 100-108; 6, pp. 128-133; 2 (1903), Nos. 7, pp. 149-152; 8, pp. 178-182; 9, pp. 200-209).—Numerous methods which have been proposed for the detection of heated milk are classified and described, and the results of tests by the author are given in connection with the discussion of each method. A bibliography is appended. Certain simple and easily made tests based upon color reactions are considered as showing conclusively whether milk has been heated to 78 to 80° C., at which temperature the danger from pathogenic germs is practically eliminated. Chemical methods based upon

determining the absence of lactalbumin serve to determine if milk has been heated to 80 to 85°, but the methods are not so suitable for practical purposes. Some of the methods are considered satisfactory in recognizing mixtures of raw and heated milk.

The hygienic differentiation of market milk and its derivatives by biological methods, V. SION and N. LAPTES (*Ztschr. Fleisch. u. Milchhyg.*, 13 (1903), Nos. 1, pp. 4-7; 2, pp. 33-37).

Milk, H. DE ROTHSCILD (*Le lait. Paris: Octave Doin, 1903, pp. 90*).—This little book deals with pasteurization as applied to the dairy, the pasteurization and sterilization of milk, methods of analysis, and milk adulteration. A brief bibliography is appended.

The bacterial flora of freshly drawn milk, F. C. HARRISON and M. CUMMING (*Jour. Appl. Micros. and Lab. Methods*, 5 (1902), Nos. 11, pp. 2029-2038; 12, pp. 2086, 2087; 6 (1903), Nos. 1, pp. 2130, 2131; 2, p. 2181).—The résumé which is given of the literature of this subject shows that decidedly different results have been obtained by various investigators. In the experiments reported by the authors samples of the fore and after milk of a number of cows were carefully collected in sterile test tubes and studied as regards the number and species of bacteria present. Great variations were observed in the numbers of colonies which developed on gelatin plates. The results of a large number of determinations showed on an average from 25,000 to 50,000 bacteria per cubic centimeter in the fore milk. The number in the stripings varied from none to 57,000 per cubic centimeter, varying greatly with the rapidity of taking the sample.

The several species found constantly present in the milk of all the cows were systematically studied as were also all the species found in the milk of one cow. Owing to their characters being so slightly marked, except in the case of *Bacillus acidi lactici*, the identification of the different species was difficult. Three lactic acid bacteria, *Bacillus acidi lactici* (Nos. 206 and 202 of Conn) and *B. lactis aerobans* (Conn 197), were the only species found in all the samples and they comprised at least 95 per cent of the bacteria present. The following species, of which descriptions are given, were more or less variable in their presence: *Bacillus halofaciens* n. sp., *Micrococcus varians lactis*, *Bacillus* 18 of Conn (?), *Bacillus* VII, *Bacterium* VIII, *Bacterium exiguum*, and *Micrococcus* X. All the species described were facultative anaerobes. The optimum temperature for growth was 37° C. Conditions existing in the udder were therefore probably favorable to their growth. The anaerobic faculty was especially marked in the case of the lactic-acid bacteria, which accounts for their preponderance over the other species.

Udders were inoculated with *Bacillus prodigiosus*, *B. exiguum*, and *B. fluorescens liquefaciens* by smearing the ends of the teats with cultures. The bacilli soon disappeared from the milk.

Cultures were made from the livers and udders of 3 cows which had been dry for several weeks previous to slaughter. Bacteria were found in the livers of all 3 and in the udders of 2 cows. While the results are not considered sufficient to warrant a positive assertion they point toward infection by way of the blood or lymph rather than through the teat.

"In reviewing the subject, there can be no doubt that the number of bacteria present in the milk as it exists before being drawn from the udder is somewhat startling, and were nothing more than an enumeration of the germs given there might be some occasion for alarm. However, a systematic study of the germs proves that with the possible exception of rare cases, this source of bacterial life is much more beneficial than baneful to the average consumer of milk and its products."

The bibliography given includes 25 references.

Improved method of studying milk bacteria, H. W. CONN and W. M. ESTEN (*Rev. Gén. Lait*, 2 (1903), Nos. 9, pp. 193-200; 10, pp. 224-233).—The authors have

endeavored to devise a method for determining with rapidity and with some degree of accuracy the numbers of the different species of bacteria in milk. For this purpose two culture media have been used, one prepared like ordinary gelatin with the addition of milk sugar and litmus, and one prepared by the addition of 15 per cent of gelatin to whey. The gelatin medium gives a larger number of colonies and the whey medium a sharper differentiation of the different kinds. Plate cultures are made, the sample of milk being diluted with sterile water to such an extent that from 200 to 300 colonies develop on each. The degree of dilution varies ordinarily from 50 to 600 in moderately fresh milk and frequently above 200,000 in milk which has been kept warm for 2 or more days. The cultures are kept at about 20° C. for 5 or 6 days, when the total number of colonies is determined and a study is made of the different kinds as recognized by their appearance, the number of each type being ascertained. No subsequent cultures are made. The authors have found it possible in this way to differentiate accurately a large variety of colonies, several of the more important of which are briefly described. The colonies are considered as representing groups of species rather than as necessarily representing individual species. This method of identifying the different species and determining approximately their number, while not regarded as very accurate, has the advantage of being rapid and of permitting observations to be made on the rise and fall of different types of bacteria in milk in a way not hitherto considered possible.

Bitter milk and cheese, F. C. HARRISON (*Ontario Agr. Col. and Expt. Farm Bul.* 120, pp. 32, figs. 7).—This has been noted from another source (*E. S. R.*, 14, p. 489).

The percentage of water in Canadian creamery butter, F. T. SHUTT (*Ontario Dept. Agr., Dairy Division Bul.* 4, n. ser., 1902, pp. 6).—Determinations were made of the water content of 75 samples of butter received from creameries in different parts of Canada and of 30 samples obtained in Montreal from packages ready for export. The butter was practically all manufactured in July and August, and was considered representative of the butter prepared for export to England. The maximum, minimum, and average water content of the samples from creameries was, respectively, 16.77, 8.92, and 12.16 per cent, and of the warehouse samples 15.37, 7.94, and 12.69 per cent. Of the 105 samples 92 showed less than 14 per cent of water. Only 1 sample contained more than 16 per cent and this was of butter churned above 60° F. and washed at 64°, temperatures noted as unusually high in Canadian creamery practice. The results are considered as fairly conclusive evidence that Canadian creamery butter is well within the limit of 16 per cent allowed by the English law. As regards the relation of the water content to inspection rating the author states that "the appearance of a butter as sampled affords, generally speaking, no criterion as to its moisture content."

Control of rusty spot in cheese factories, H. A. HARDING and G. A. SMITH (*New York State Sta. Bul.* 225, pp. 303-329).—The trouble known as rusty spot manifests itself in cheese from 4 to 8 days after pressing and is characterized by the occurrence throughout the interior of the cheese of bright red or yellowish-red spots the size of a pin point and larger. The time of their appearance is hastened by a warm curing room and retarded by a cool one. The spots are usually most noticeable on the surface of gas holes and other openings, where in the presence of free moisture they may form a yellowish-red blotch the size of a thumb nail. The trouble is most evident in moist cheese made for home trade. The whole interior of the cheese may in bad cases present an unevenly colored appearance. The use of cheese color is not entirely successful in disguising the rusty spots. Outbreaks have occurred in nearly every section of the State where white cheese is made, and have been reported since 1883. In an earlier bulletin of the station (*E. S. R.*, 13, p. 85) this subject was briefly discussed and the causal relation of *Bacillus rudensis* was confirmed. Experiments made at 4 factories during 1901 and 1902 for the control of this trouble are recorded in detail in the present bulletin.

The disinfection of factories by the use of steam was the method employed, the results showing that the thorough application of this treatment three times per week will prevent financial loss except under very unusual conditions. "In attempting to combat this trouble in any factory the first step is a thorough cleaning up of the factory and its surroundings. A few loads of gravel will do away with the mud by the weigh can and the whey tank, and good drainage should be provided for the factory waste. The walls and ceiling of the room in which the cheese is made should be cleaned and preferably whitewashed, and the floor scrubbed with hot lye. The weigh can and all the utensils which come in contact with the milk should be steamed thoroughly three times per week. This can be best accomplished by placing the utensils in a vat, drawing a heavy canvas cover tightly over the top, and turning in the steam. In 5 minutes the heat should be up to 180° F. in all parts of the vat, and 15 minutes more above this temperature will suffice. The weigh can is best treated by inverting and turning in the steam for 20 minutes through the faucet. The heating of the all-metal cheese hoops can be carried out according to the same plan, but Frasier hoops present some difficulties. The accumulation of fat in the crevices makes a special place for heating desirable, and our experience in heating the wooden followers is not sufficient to justify us in recommending it as a regular procedure, although heating occasionally does not seem to be harmful. The observations given in connection with [one] factory indicate that heating these followers is desirable. Considered both as a means of preventing the return of a considerable number of *Bacillus rudensis* to the farms, and as a means of holding the whey sweet and in first-class condition for feeding, the heating of the whey to 160° F. is desirable."

Considerable work was done to determine the source of contamination, with results not entirely conclusive. The original source of infection was not determined in any case. "While under ordinary conditions the factory seems to be the main seed bed of the germs, cheeses made from the milk of individual patrons indicate that at times the milk of some patrons contains the germs causing rusty spots."

Ripening of cheese in cold storage compared with ripening in the ordinary curing room. H. H. DEAN, F. C. HARRISON, and R. HARCOURT (*Ontario Agr. Col. and Expt. Farm Bul. 121, pp. 12, fig. 1*).—The experiments reported in this bulletin were made during the period from April to November, 1901. The temperature of the cold-storage room during the season averaged 37.8° F. and the humidity 91.6 per cent. The average temperature of the ordinary curing room was 63.8° and the humidity 79.1 per cent. In each of the 26 experiments conducted 4 or 5 cheeses of about 30 lbs. each were made. Cheese A was immediately placed in cold storage; cheeses B, C, and D were placed for 1, 2, and 3 weeks, respectively, in the ordinary curing room and then transferred to cold storage; cheese E was ripened in the ordinary way.

Cheese in the curing room ripened about as much in one week as cheese in cold storage did in one month. At the end of 86 days the numbers of lactic-acid bacteria in the cold-storage and curing room cheeses were, respectively, seven-eighths and one-fortieth of the numbers present at the beginning of the ripening period. "The significance of this fact is that there is little chance for undesirable bacteria to produce bad flavors in the cold-storage cheese owing to the large number of the lactic-acid bacteria, the proportion of the lactic-acid bacteria to certain undesirable kinds being much greater than is usual under ordinary conditions."

During the first month the loss in weight was as follows: Cheese A 2.1, B 2.8, C 3.2, D 3.6, and E 4.4 per cent. The averages of all scorings made by months during the season were as follows: Cheese A 92.4, B 91.6, C 90.9, D 90.7, and E 85 per cent. The cheeses ripened in cold storage were especially uniform in quality. Such cheese was not observed as spoiling quickly when exposed to ordinary temperatures. Mold, which was equally troublesome in the refrigerator and the curing room, was kept in check by the use of formalin.

"At present, we are not prepared to say that all cheese should be ripened in cold storage; but we certainly think that cheese made during the hot weather, say in the months of July and August, should be placed in cold storage as soon as possible after they are made." The investigations are being continued.

Plans and specifications of a cool cheese-curing room, J. A. RUDDICK (*Ontario Dept. Agr., Dairy Division Bul. 7, n. ser., 1903, pp. 29, dgmns. 8*).—The plans provide for office, testing room, store room, etc., in connection with the curing room, and are intended to illustrate the system of insulation and cooling rather than to serve as a model as regards size and arrangement. The cooling is secured by means of ice. No difficulty was experienced at the Brockville curing room in maintaining a temperature between 54 and 60° F. from June 18 to September 30 by the use of 100 tons of ice, during which time 6,644 cheeses were received.

Fourth report of the State Dairy Bureau, 1900-1902 (*Rpt. California State Dairy Bureau, 4 (1900-1902), pp. 56*).—This contains a review of the work of the Dairy Bureau during the 2 years ended October 1, 1902, statistics of the dairy industry in California, analyses of a number of samples of butter and cheese, lists of creameries and cheese factories in California, and the State dairy laws.

Dairying division, J. A. KINSELLA (*New Zealand Dept. Agr. Rpt. 1902, pp. 135-218, pls. 5*).—This is a report on the progress of the dairy industry in New Zealand during the year and on dairy conditions in Australia as observed by the author. Statistics are given of the amount and value of butter and cheese exported from New Zealand, and numerous suggestions are made as regards methods of making butter and cheese, grading dairy products, building and equipping factories, testing cows, etc.

VETERINARY SCIENCE AND PRACTICE.

The microbic diseases of animals, E. NOCARD and E. LECLAINCHE (*Les maladies microbiennes des animaux. Paris: Masson & Co., 1903, vols. 1, pp. 668; 2, pp. 645*).—The present edition of this work has been entirely rewritten and considerably enlarged. Some chapters required but little change while it was found possible to contract the discussion of certain other subjects. A number of new subjects have been introduced, among which the more important are the diseases due to hematozoa, actinobacillosis, pseudotuberculoses, fowl plague, horse disease, canine typhoid, and pasteurelloses of horses and calves.

Manual of veterinary medicine, E. COURTENAY (*London: Ballière, Tindall & Cox, 1902, 2. ed., pp. X + 573*).—The present edition has been revised and edited in so far as was necessary by F. T. G. Hobday. The volume treats especially of the principal diseases of horses and cattle, and includes the following subjects: Diseases of the respiratory system, strangles, lymphangitis, skin diseases, eye diseases, nervous diseases, inflammation, diseases of the bones, wounds, diseases of the feet, teeth, stomach and intestines, liver, spleen, pancreas, and urinary system, glanders, variola, castration, pregnancy, azoturia, cardiac diseases, blackleg, and hog cholera.

Outlines of veterinary hygiene for veterinarians and students, F. NIEMANN and O. PROFÉ (*Grundriss der Veterinär-Hygiene für Tierärzte und Studierende. Berlin: Louis Marcus, 1903, pp. 418, figs. 50*).—The purpose of this volume is to give a concise account of various subjects relating to the hygiene of domesticated animals. Unnecessary details are omitted in order that the book may be most convenient for use by practical veterinarians and sanitary officers. The volume contains an account of the hygiene of stables, and the care and feeding of animals. The greater part of the volume, however, is occupied with a discussion of animal plagues, methods of combating them, and veterinary bacteriology. One chapter is devoted to an account of knackers' establishments and methods for disposing of infectious cadavers.

Practical veterinary advice for stock owners, A. H. ARCHER (*London: Vinton & Co., Ltd., 1901, 2. ed., pp. 83*).—The purpose of this volume is to assist stock owners

in maintaining their animals in healthy condition. The more important diseases of domestic animals are described and information is given which will enable owners to deal with such cases. The various diseases discussed are classified according to the part of the body affected. The author discusses also the nature of simple operations and gives a list of drugs, with the size of doses for various animals.

A treatise on surgical therapeutics of domestic animals, P. J. CADRIOT and J. ALMY, trans. by A. LIAUTARD (*New York: W. R. Jenkins, 1902, vol. 1, pt. 3, pp. 189-323, figs. 33*).—This part of the translation of the French text-book on surgical therapeutics includes chapters on granulations, mycoses, tumors, diseases of the skin, serous membranes, muscles, and tendons. The purpose of the translation is to make available to American veterinarians a thorough account of the subject as presented in the French original.

Manual of bacteriology, R. MUIR and J. RITCHIE (*New York: The Macmillan Co., 1903, Amer. ed., pp. XX+565, figs. 170*).—This edition is revised and edited from the third English edition by N. Mac L. Harris. The general scope of the work has been somewhat enlarged and alterations have been made in certain chapters, especially chapters 2, 3, 4, 15, and 17. The section on bibliography has been considerably extended. The subjects treated in the volume include general morphology and biology of bacteria; methods of cultivation; microscopic methods; bacteria in air, soil, and water; fungi; relations of bacteria to disease; inflammatory and suppurative conditions; venereal diseases; tuberculosis; leprosy; glanders; actinomycosis; anthrax; typhoid fever; diphtheria; tetanus; malaria; influenza; immunity; smallpox; hydrophobia; malarial fever; amebic dysentery, etc.

Annual report on investigations in the field of veterinary medicine, ELLENBERGER ET AL. (*Jahresber. Leist. Geb. Vet. Med., 21 (1901), pp. 312*).—In this report the authors have brought together brief references to the literature of veterinary science for the year 1901. The literature is classified in an elaborate system according to the subject-matter, the main features of some of the more important literature are briefly discussed, and reference to the literature is made easy by an author and subject index.

Veterinary science and its problems, O. MALM (*Tidsskr. Norske Landbr., 9 (1902), No. 7, pp. 304-320*).

Disinfection and disinfectants, M. J. ROSENAU (*Philadelphia: P. Blakiston's Son & Co., 1902, pp. XII+353, pls. 21, figs. 90*).—The purpose of this volume is to present in a brief and convenient form the practical methods of disinfecting after the presence of various infectious diseases of man and animals. The subjects discussed include physical disinfectants, gaseous disinfectants, chemical solutions, insecticides used in destroying insects which carry diseases, disinfection of houses, ships, etc., and specific directions for disinfecting after particular diseases.

Text-book of meat hygiene, with special references to inspection of food animals and meat, R. ENDELMANN (*Lehrbuch der Fleischhygiene, mit besonderer Berücksichtigung der Schlachtvieh- und Fleischschau. Jena: Gustav Fischer, 1903, pp. 336, pls. 2, figs. 172*).—In this volume the author discusses in a concise manner the history of meat inspection, traffic in animals used for food, morphology and chemical composition of important tissues and organs, means of preparing and preserving meat, legal regulations with regard to meat traffic and the organization and practice of inspection of food animals and meat, while the larger part of the volume is occupied with a discussion of the various diseases and post-mortem changes which come under the notice of the meat inspector. Chapters are also presented on the arrangement of slaughterhouses and cattle yards and on poisoning from meat and sausage.

The conditions which are necessary for the general extension and unification of the inspection of meat in public abattoirs, G. BARRIER (*Compt. Rend. 10. Cong. Internat. Hyg. et Démogr., Paris, 1900, pp. 121-135*).—The author recommends compulsory inspection and slaughter in public abattoirs, the abandonment of

private slaughterhouses, and thorough sanitary police measures in preventing the spread of disease through the agency of abattoir products.

Serum agglutination and its value in meat inspection, H. MIESSNER and HERBST (*Arch. Wiss. u. Prakt. Tierch.*, 28 (1902), No. 3-4, pp. 359-371).—A critical review of the literature of this subject is presented. It was determined by Bordet that the serum of guinea pigs, after these animals had received from 5 to 6 intraperitoneal injections of rabbit blood, possessed the power of agglutinating and destroying the red blood corpuscles of rabbits. The experiments undertaken by the author were for the purpose of determining whether this discovery could be used to advantage in identifying meats in doubtful cases. An extensive series of experiments was conducted with this object in view. It was found that in serum reaction a valuable means was furnished for distinguishing between different kinds of meats. It is believed, therefore, that the identification of meat by means of the action of its specific serum constitutes a decided step in advance in the difficult problem of recognizing the kind of animal from which samples of meat were taken.

Results of strict sanitary regulations in Arizona, J. C. NORTON (*Jour. Comp. Med. and Vet. Arch.*, 23 (1902), No. 10, pp. 613-619).—The author presents a summary account of the sanitary regulations which have been put in force in Arizona for the purpose of controlling animal diseases. A rigid quarantine has been placed on districts where glanders appeared. The Texas fever infection was found in only one irrigated valley where lands were fenced. During the past 2 years the extent of sheep scab has been greatly reduced. Hog cholera does not appear to become established in the territory, but constant care is required to prevent the introduction of this disease, as well as swine plague. Turkey buzzards are said to have been instrumental in some cases in spreading swine plague from one locality to another. During the past season no cases of tuberculosis were noted in the territory, and only 2 horses were condemned on account of glanders.

Report of the State veterinarian of Washington for 1901 and 1902, S. B. NELSON (*Seattle: Metropolitan Press, Inc.*, 1902, pp. 16).—It is stated that during the years covered by this report the services of the State veterinarian have been in greater demand than ever before. The veterinarian's attention was chiefly called to glanders, mange, tuberculosis, blackleg, actinomycosis, contagious keratitis, contagious abortion, and hog cholera. Fewer horses were found to be infected with glanders than during the previous year. Mange in horses is said to have assumed such serious proportions that legislation on the subject is recommended. A number of tuberculin tests were made and experiments were conducted for the purpose of devising a satisfactory treatment for contagious keratitis. In the treatment of this disease the author recommends an eyewash containing 1 gr. zinc sulphate and 3 gr. morphin sulphate; a few drops of this solution should be dropped into the eye night and morning. A copy of the law creating the office of State veterinarian in Washington is also given.

Thirteenth annual report of the veterinary service in Hungary, F. HUTYRA (*Jahresber. Vet. Ungarn*, 13 (1901), pp. 148, map 1).—As in previous reports the author presents a general account of the status of government veterinary service in Hungary, together with notes on the prevalence of the more important animal diseases. The following diseases receive especial discussion: Anthrax, rabies, glanders, foot-and-mouth disease, pleuro-pneumonia, sheep pox, scabies, swine erysipelas, swine plague, hog cholera, buffalo plague, tuberculosis, lungworm disease, actinomycosis, etc.

Annual report of the civil veterinary department, Bengal, and of the Bengal Veterinary College, 1901-2 (*Calcutta: Bengal Secretariat Press*, 1902, pp. 24).—Notes are given on veterinarian dispensaries in various parts of Bengal, also on glanders, rinderpest, inspection of stock cars, and on the breeding of cattle, horses, ponies, and mules. A brief report is given of the work of the Bengal Veterinary College.

Report of the chief inspector of stock and brands, C. J. VALENTINE (*Min. Agr. South Australia Rpt. 1902*, pp. 22-25).—Brief notes are given on the prevalence of some of the more important diseases affecting sheep, cattle, horses, and hogs. These diseases include foot rot, pleuro-pneumonia, tuberculosis, actinomycosis, etc.

The toxic substances in normal sera, CARRÉ and VALÉE (*Compt. Rend. Soc. Biol. Paris, 54 (1902), No. 6, pp. 176, 177*).—Experiments were conducted by the authors for the purpose of determining the toxic principles contained in the sera of cattle, sheep, goats, dogs, horses, and donkeys. The results obtained in these experiments lead the authors to conclude that the bactericide, globulicide, and toxic substances of sera are identical, or, in other words, that the same toxic substance exercises the action of destroying bacteria and the red blood corpuscles, and producing toxic effects.

The antiseptic value of Crede's colloidal silver preparation and its action in infection, E. COHN (*Centbl. Bakt. u. Par., 1. Abt., 32 (1902), Nos. 10, Orig., pp. 732-753; 11, pp. 804-809*).—A critical review of the literature of this subject is given by the author. A large number of experiments were conducted for the purpose of determining its antiseptic value, in small laboratory animals, such as rabbits and guinea pigs. The silver preparation was administered either before or after infection with Staphylococci, Streptococci, anthrax bacilli, and cholera vibrios. During these experiments it was found that the soluble silver preparation, even in very large doses, had no effect either of a local or general nature upon the infectious processes. The pathogenic organisms were not destroyed or even checked in their growth by the silver preparation. In preliminary experiments it was found that the colloidal silver had no toxic effect upon healthy animals. It was also found that within 45 minutes after the colloidal silver was introduced into the blood it could no longer be demonstrated. It appears to be precipitated immediately after its introduction into the body, and the precipitate thus formed has no antibacterial action.

The bactericide power of fluorid of silver as compared with silver nitrate, carbolic acid, and corrosive sublimate, H. KERESZ (*Centbl. Bakt. u. Par., 1. Abt., 32 (1902), No. 8-9, pp. 644-648*).—A series of experiments were undertaken for the purpose of comparing fluorid of silver as prepared by Professor Paterno, under the name Tachiol. Bacteria upon which these different antiseptics were allowed to act were tubercle bacillus, anthrax bacillus, typhoid bacillus, and anthrax spores. It was found that fluorid of silver possessed about the same bactericide power as silver nitrate. When used in a 1 per cent solution its antiseptic power was equal to a 5 per cent solution of carbolic acid. All of these substances, however, were found to possess a lower bactericide power than corrosive sublimate.

The decomposition of iodid of potash in the organism by means of nitrites, A. STEKANOW (*Arch. Exper. Path. u. Pharmacol., 47 (1902), No. 5-6, pp. 411-416*).—The author made extensive analyses of different organs of rabbits and dogs and demonstrated the absence of nitrites in the gray brain substance, liver, stomach, spleen, brown substance of the kidneys, muscles, and blood. Nitrites were found in the white brain substance, lung tissue, bronchial glands, small intestines, medullary substance of the kidneys and lymphatic glands. The author believes from his observations that iodid of potash is for the most part decomposed in the presence and by the agency of nitrites.

The action of lecithin on the leucocytes, H. STASSANO and F. BILLON (*Compt. Rend. Soc. Biol. Paris, 54 (1902), No. 6, pp. 167-170*).—A large number of intravenous inoculations of emulsion of lecithin in rabbits produced as a constant result an increase in the number of leucocytes after each injection. When the lecithin was administered by intraperitoneal injection similar results were obtained, the leucocytes increasing in number to a considerable extent, especially around the point of inoculation. In the exudation produced by the lecithin the polynuclear leucocytes were surrounded and destroyed by the mononuclear cells.

The permeability of the placenta for micro-organisms, and its phagocytic power, N. K. NEELOW (*Centbl. Bakt. u. Par., 1. Abt., 31 (1902), No. 14, Orig., pp. 691-693*).—The experiments reported in this article were made on pregnant rabbits and the objects of the experiments were to determine whether nonpathogenic micro-organisms were able to pass from the mother to the fetus through the placenta, and whether the placenta exercised any phagocytic action. As a result of these experiments it was found that nonpathogenic bacilli did not pass through the healthy placenta. The phagocytic power of the placenta was found to be very slight.

Investigations on a new pathogenic species of yeast, E. COHN (*Centbl. Bakt. u. Par., 1. Abt., 31 (1902), No. 15, Orig., pp. 739-748*).—Cultures were received from Klein of a species of yeast discovered by him to be pathogenic. The original material was found in milk. The morphological characters of the organism and its behavior in artificial cultures are described. The author conducted a number of inoculation experiments with this organism, on small and large experimental animals. White and gray mice were invariably killed by such inoculations, within from 4 to 11 days. Young white rats, however, proved to be immune. Symptoms of disease, but without fatal results, were produced in rabbits, while in guinea pigs more violent inflammatory lesions were produced as the result of inoculations. A pig 3 months old inoculated in the auricular vein exhibited a purulent conjunctivitis after 8 days, together with considerable disturbance of the general health. The animal finally recovered entirely from the symptoms. Similar inoculation experiments with a dog resulted also in the development of purulent conjunctivitis, from the discharges of which the organism was recovered. The dog died after 3 days. Experiments with pigeons showed that these birds were not susceptible. A number of feeding experiments were conducted with mice, and infection took place in all cases. These experiments, however, had to be abandoned, and the ultimate result of infection could not be observed.

A bacterium resembling that of bubonic plague, E. KLEIN (*Centbl. Bakt. u. Par. 1. Abt., 32 (1902), No. 10, pp. 673-675, figs. 3*).—*Bacterium bristolense* was isolated from rats found dead on a vessel from Asia Minor. Notes are given on the appearance and staining properties of this organism. Small intraperitoneal doses of the organism were found to have a fatal effect upon guinea pigs within 24 hours. Subcutaneous injections of cultures were fatal to the majority of experimental animals.

A bacillus liable to be mistaken morphologically for the bacillus of tetanus, F. F. BUSHNELL (*Amer. Vet. Rev., 26 (1902), No. 5, pp. 405-410*).—A bacillus was obtained from pus in a case of poll-evil, and cultures were made of the organism upon agar, gelatin, and other nutrient media. The bacillus is described in detail. It decolorizes when treated by Gram's method, and the spores resist a temperature of 80° C. for 45 minutes. The organism differs from the tetanus bacillus in that it is a facultative aerobe, is motile in young cultures, does not liquefy gelatin, does not take the Gram stain, is not pathogenic for guinea pigs.

Absorption of tetanus toxin, A. MARIE and V. MORAX (*Ann. Inst. Pasteur, 16 (1902), No. 11, pp. 818-831*).—The authors' experiments were made on mice, rabbits, and other laboratory animals. It was found that the absorption of the tetanus toxin by the peripheral nerves was the result of a specific affinity of this substance for the axis cylinder. This affinity is not manifested in experiments made in vitro, but is sufficiently apparent in living animals. The fixation of the tetanus toxin by the nerves takes place very rapidly. It is proposed in future experiments to study the rôle of different parts of the nervous system in absorbing tetanus toxin.

Observations on *Bacillus coli communis* from certain species of domesticated animals, V. A. MOORE and F. R. WRIGHT (*Amer. Vet. Rev., 26 (1902), No. 6, pp. 524-533*).—Notes are given on the appearance, biology, and pathogenic power of cultures of this bacillus obtained from horses, cattle, sheep, pigs, dogs, and chickens.

The variation in the pathogenic power of cultures from different species of animals was very marked.

The present aspect of the tuberculosis problem in the United States, S. A. KNOPF (*Jour. Amer. Med. Assoc.*, 39 (1902), Nos. 21, pp. 1309-1314; 22, pp. 1367-1373, figs. 16).—Circular letters of inquiry were sent to various parts of the different States and Territories of this country for the purpose of learning the extent and nature of laws for the control of tuberculosis. The answers received to these inquiries are summarized by the author. From a study of this summary it is apparent that a great lack of interest prevails in many States and cities with regard to the danger of transmission of tuberculosis from animals to man or from one individual to another.

Recent investigations concerning the relation of human and bovine tuberculosis, D. E. SALMON (*Jour. Amer. Med. Assoc.*, 39 (1902), No. 25, pp. 1571-1574).—Notes are given on recent experiments and observations which indicate the inoculation of monkeys with bovine tubercle bacilli, and the transmission of tuberculosis from man to cattle and from cattle to man. Statistics are given concerning tuberculosis among children who drink cows' milk, and brief notes are presented on European and American customs with regard to sterilization of milk.

The intertransmissibility of human and bovine tuberculosis, R. R. DINDWIDIE (*Jour. Amer. Med. Assoc.*, 39 (1902), No. 25, pp. 1574-1577).—The author discusses the anatomical lesions in cases of bovine tuberculosis and devotes special attention to an account of experiments which have been made to determine the comparative virulence of bovine tubercle bacilli for different species of animals. During the author's first experiments he was inclined to the belief that the bovine tubercle bacilli exercised a sort of selection among different animals, but later experiments indicate that this organism possesses an indiscriminate excess of virulence over the human tubercle bacillus.

Sanitary measures for the prevention of tuberculosis in New York City and their results, H. M. BIGGS (*Jour. Amer. Med. Assoc.*, 39 (1902), No. 26, pp. 1635-1640).—The origin of tuberculosis in human patients and the means of transmission of this disease from man to man and from tuberculous animal products to man are discussed. Attention is called to the slow development of tuberculosis and the consequent difficulties in determining the source of infection. The author urges the desirability of exercising special precautions in preventing the transmission of this disease by whatever agency.

Transmission of bovine tuberculosis to man by accidental inoculation, and the experimental reinoculation of calves, SPRONCK and HOEFNAGEL (*Ann. Med. Vet.*, 51 (1902), No. 11, pp. 589-599).—A detailed account is given of a case in which the authors believe that bovine tuberculosis was transmitted to man through a skin wound. The wound was on the finger and the apparent results of infection were seen in swelling of the arm and inflammation of some of the lymphatic glands. Material taken from the finger, which was amputated in treating the case, was used in inoculating guinea pigs, in which tuberculosis developed after the usual incubation period. The organism was then passed a second time through a guinea pig and virus obtained from the second guinea pig was used in inoculating a heifer, which rapidly developed signs of tuberculous infection.

Tubercular peritonitis in early life, T. M. ROTCH (*Jour. Amer. Med. Assoc.*, 40 (1903), No. 2, pp. 69-73).—Notes are given on the clinical symptoms, diagnosis, and pathological anatomy of tubercular peritonitis in children, with regard to its relationship to bovine tuberculosis. The mesenteric lymph glands may often be affected as well as the alimentary tract, lungs, and other organs. The region of the infection in such cases is frequently doubtful.

Ohio combating tuberculosis, J. C. BURNESON (*Amer. Vet. Rev.*, 26 (1902), No. 4, pp. 328-333).—Notes are given on the methods adopted in inspecting cattle in

Ohio and in the application of the tuberculin test. Attention is called to the desirability of reasonable, effective, and uniform legislation for controlling this disease.

Tuberculosis in the suprarenal glands in cattle, A. M. BERGMAN (*Arch. Wiss. u. Prakt. Thierh.*, 28 (1902), No. 5, pp. 496-504).—In the author's opinion tuberculosis affects the suprarenal glands with considerable frequency. In all 21 cases were investigated, among which 1 gland was affected in 9 cases and both glands in the other 12. The suprarenal glands are also affected with tuberculosis in the case of hogs. The disease in this situation is of a chronic nature with pronounced tendency to the formation of calcareous deposits in the pathological foci.

Statistics on tuberculosis in hogs, N. ZELENIN (*Arch. Vet. Nauk, St. Petersburg*, 32 (1902), No. 8, pp. 693-727).—Detailed statistical notes are given on the extent of tuberculosis in the various parts of Russia. Among 178,520 hogs examined during the years 1895-1899, tuberculosis was found in 5,679, or 3.2 per cent. As a result of further extensive compilation of statistics it was found that from 7.6 to 12.9 per cent of hogs were condemned on account of infection with tuberculosis.

Tuberculosis of the udder in a mare, C. PARASCANDOLO and V. DE MEIS (*Arch. Wiss. u. Prakt. Thierh.*, 29 (1903), No. 1-2, pp. 198-208).—The literature of mammary tuberculosis is briefly reviewed and detailed notes are given on a case of mammary tuberculosis in a mare. The case is considered to be rather important on account of the relative infrequency of the disease in horses.

Tuberculin, H. F. PALMER (*Jour. Comp. Med. and Vet. Arch.*, 23 (1902), No. 7, pp. 410-416).—Notes are given on the nature of tuberculin, its reliability as a test for tuberculosis, and the method of making the test with it. A brief account is also presented of the nature, use, and effectiveness of mallein.

Actinomycosis of cat. le, I. I. SHUKOVICH (*Uchen. Zapiski Kazan. Vet. Inst.*, 19 (1902), Nos. 3, pp. 193-230; 4, pp. 231-335).—In this article the author presents an exhaustive discussion of the symptoms of actinomycosis, the morphology of the actinomycotic tumors, the differential diagnosis between actinomycosis and pseudo-actinomycosis due to *Streptothrix* and also bacterial pseudo-actinomycosis. The biology of various forms of actinomyces is discussed in detail, with numerous references to the literature of the subject. Actinomyces is divided into 3 groups according to differences in morphology and biology. The pathological histology and pathogenesis of different forms of actinomycoses are also discussed in great detail.

Actinomycosis from a bacteriological standpoint, W. SILBERSCHMIDT (*Compt. Rend. 10. Cong. Internat. Hyg. et Démogr., Paris, 1900*, pp. 90, 91).—The author's conclusions from his study of this disease are as follows: Actinomycosis is not a simple disease of uniform etiology in all cases. The organisms isolated by Wolff, Israel, and Bostrom are not always found in cases of the disease. The organisms of actinomycosis belong to the *Streptothrix* group and show many points of resemblance to the tubercle bacillus.

Experimental researches on the variability of *Bacillus anthracis*, H. MARTEL (*Recherches expérimentales sur la variabilité du *Bacillus anthracis**. Paris: C. Naud, 1902, pp. 85, pl. 1).—An extensive series of experiments was conducted for the purpose of determining the influence of different conditions of environment upon the morphology and biology of the anthrax bacillus. As a result of these experiments it was found that anthrax bacillus exhibits a number of variations, either spontaneously or under the influence of artificial manipulation. The filamentous form of the organism, which is the normal form of the bacillus, when cultivated in a liquid nutrient medium may be changed into straight short rods when inoculated into dogs. Several passages through this animal results in a short bacillus capable of reproducing by fission and sporulation. This morphological variation of the organism is difficult to maintain. It is only necessary to pass the organism through very sensitive animals, such as young cats and guinea pigs, or to cultivate it on potatoes or agar-agar in order to obtain the original form. The functional variations of the anthrax bacillus are

perhaps equally great. It is difficult to acclimate the organism to carnivora, especially to adult dogs. Anthrax bacillus from sheep is of medium virulence and is not pathogenic for adult dogs, even when inoculated in large doses. Some cultures of the bacillus from cattle are much more virulent than others. Successive passages of anthrax bacillus of weak virulence through rats, beginning with very young rats and ending with adult specimens, has the effect of greatly increasing the virulence. The vitality and virulence of anthrax bacillus are modified by antiseptics. These modifications vary according to the origin of the bacillus and the nature of the antiseptics. Cultures which have been maintained in a laboratory for a long time appear to be more susceptible than fresh cultures.

The influence of the tanning process upon anthrax spores, H. KESSLER (*Inaug. Diss., Univ. Würzburg, 1902, pp. 31*).—A study was made of the effect of the various chemicals and processes used in tanning leather upon anthrax spores which happen to be present upon the skin. As a result of these investigations it was found that chemicals and processes in common use can not be said to destroy all of the anthrax spores upon the skins. While a portion of the spores are induced to germinate during the softening process to which the skins are subjected, other spores are formed during the same process, so that future treatment must be calculated to destroy spores if the skins are to be rendered perfectly sterile. Solutions of caustic lime were found insufficient to destroy anthrax spores during the period of time occupied by the tanning process. In some experiments it was found that the spores withstood these solutions for periods of 12 to 17 days. The spores are easily destroyed by a 1 per cent solution of formalin if allowed to operate for a period of 48 hours.

An experiment in preventive vaccination for anthrax in the government of Yaroslav in May and June, 1902, A. V. DEDYULIN (*Arch. Vet. Nauk., St. Petersburg, 32 (1902), No. 10, pp. 862-881*).—In these experiments 2 vaccines were used and the animals upon which the experiments were made were horses and cattle. No death occurred among 125 horses and 579 cattle which were treated with a double vaccine.

The value of cooperation in the sanitary control of our periodic epizootics of anthrax, W. H. DALRYMPLE (*Jour. Comp. Med. and Vet. Arch., 23 (1902), No. 8, pp. 484-498*).—Historical notes are given on the outbreaks of anthrax in former times and attention is called to the agency of birds, carnivorous animals, and insects in spreading contagion. Notes are also given on other means of spreading the disease, especially by carcasses of animals dead of anthrax, and by wool. The quarantine and sanitary measures which are indicated in an outbreak of anthrax are briefly discussed. The method of preventing anthrax by vaccination is discussed at some length.

Preventive vaccination for anthrax in the Novoladozh region in 1901, I. O. GORDZYALKOVSKI (*Arch. Vet. Nauk., St. Petersburg, 32 (1902), No. 8, pp. 653-663*).—A series of experiments was instituted for the purpose of determining the effectiveness of vaccination in preventing anthrax. As a result of the author's experiments it is concluded that when proper care is exercised in vaccinating animals, perfectly satisfactory results may be obtained from the vaccination of horses and cattle in northern regions. The second vaccination, administered in doses of 0.25 cc., renders the animals perfectly immune. Unsatisfactory results of vaccination experiments made in 1889 are explained as due to the use of too virulent cultures or improperly graduated doses.

Experimental researches on blackleg, E. LECLAINCHE and H. VALÉE (*Ann. Inst. Pasteur, 16 (1902), No. 12, pp. 931-939*).—In this article the authors report the results obtained from a continuation of their studies on blackleg. A number of different methods of vaccination were tried on cows and guinea pigs. Vaccination by a single inoculation of pure vaccine more or less attenuated is experimentally possible but is

attended with serious accidents in practice. Double vaccination with pure vaccines, even when very attenuated, is not always safe. Inoculations with a mixture of immunizing serum and virus is attended with accidents and the immunization is uncertain. The method which is preferred by the authors consists in successive inoculations with an immunizing serum and a pure attenuated virus.

Vaccination for blackleg by means of the thread vaccine, H. GEORGE (*Bul. Agr. Algérie et Tunisie*, 8 (1902), No. 22, pp. 548-550).—A brief account is given of the use of the double vaccine method in the prevention of blackleg. As compared with this method, that in which vaccine is used on a thread is considered as possessing many advantages in simplicity, safety, and efficiency.

The preparation of blackleg vaccine, C. F. DAWSON (*Amer. Vet. Rec.*, 26 (1902), No. 8, pp. 764-767).—Notes are given on the technique employed in the preparation of the virus and vaccine for prevention of the development of blackleg.

Bovine pasteurellon in the Malay Peninsula, CARRONGEAN (*Vet. Jour.*, 55 (1902), No. 330, pp. 321-327).—The author makes a report on an investigation of a supposed outbreak of rinderpest in the Malay Peninsula. It was found that the disease was not rinderpest but hemorrhagic septicemia, or bovine pasteurellon. It appears in the Malay Peninsula in a subacute, acute, or chronic form. All forms are due to the same organism, an ovoid pasteurilla. The organism varies greatly in virulence. Preliminary experiments give promise of good results with a method of preventive inoculation.

"Peste," C. NOCKOLDS (*Amer. Vet. Rec.*, 26 (1902), No. 5, pp. 411-415).—"Peste" is said to be a native term for rinderpest. This disease is reported as having almost exterminated the domesticated animals in various parts of the Philippines. Notes are given on bacteriological studies of material obtained from investigating the disease.

Texas fever and its relation to the live-stock interests of Tennessee, W. C. RAYEN (*Jour. Comp. Med. and Vet. Arch.*, 23 (1902), No. 10, pp. 625-630).—The irregular distribution of the cattle tick in Tennessee and the fact that this State lies on the boundary between the tick-free and infested portions of the country causes considerable complication in proper enforcement of sanitary measures with regard to Texas fever. It is stated that some portions of Tennessee lying south of the quarantine line are entirely free from ticks and that cattle may therefore be safely shipped from such localities to Northern States. The desirability of rational legislation based on careful examination of the territory concerned is advocated.

Some notes on redwater, J. HEWSON (*Vet. Jour.*, 55 (1902), No. 328, pp. 207-209).—Brief notes are given on the appearance of this disease in certain localities. In 1 herd of 13, 10 were affected during the course of 3 weeks.

Rhodesian redwater, F. HUTCHINSON and P. D. SIMMONS (*Agr. Jour. and Min. Rec. [Natal]*, 5 (1902), No. 20, pp. 663-670).—The authors present a summary account of observations made on trips of inspection through the country infested with this disease. Notes are given on the post-mortem appearance and clinical symptoms of the disease and on the practical methods which have thus far been found effective in controlling redwater.

The Rhodesia form of redwater, H. WATKINS-PITCHFORD (*Agr. Jour. and Min. Rec. [Natal]*, 5 (1902), No. 19, pp. 597-600).—Brief notes are given on the peculiarly virulent form of redwater in Rhodesia and on the experiments which have already been conducted for devising means of controlling the disease.

Oil-water pumps for spraying cattle to destroy ticks, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope*, 21 (1902), No. 5, pp. 427-434, pls. 2).—The description is given of a number of different makes of pumps designed for producing a mechanical mixture of kerosene and water. Some difficulty is experienced with the use of all these pumps in obtaining a mixture of uniform strength. The question of the comparative value of dipping and spraying is briefly discussed. While in Australia dipping has

proved more effective and convenient than spraying, the author believes that the spraying method may be retained in South Africa until dipping methods have been made more effective.

Articles and documents relating to the treatment of foot-and-mouth disease by intravenous injections of corrosive sublimate, according to the method of G. Baccelli (*Cura dell' afta epizootica con le iniezioni endovenose di sublimato corrosivo. Rome: G. Bertero & Co., 1902, pp. 290*).—In this volume a number of controversial articles relating to Baccelli's method of treating foot-and-mouth disease are brought together. The nature of the treatment and the present status of the controversy are outlined in an introduction by G. Loriga. The inaugural discourse of G. Baccelli, in which the method was first advocated, is also reproduced. The larger portion of the volume is occupied with reports from various parts of Italy, in which the method is stated to have given excellent results.

Prevention of foot-and-mouth disease, LOEFFLER (*Compt. Rend. 10. Cong. Internat. Hyg. et Démogr., Paris, 1900, pp. 194-197*).—On account of the infectious nature of this disease toward man strict measures should be taken for preventing the spread of the disease among human beings from outbreaks among cattle.

External ulcerative ano-vulvitis of cattle. A preliminary report, J. J. REPP (*Jour. Comp. Med. and Vet. Arch., 23 (1902), No. 9, pp. 546-562*).—The author observed a number of cases of this disease and gives an account of its symptoms and treatment, together with a discussion of previous reports on this subject. The disease may assume a mild or acute form. The observations thus far made indicate that the disease is not contagious. Swelling, reddening, and ulceration of the vulva and anus are observed, and in acute cases these ulcerations may assume a grave character and produce extensive sloughing of the tissues. The period of incubation is apparently about 1 week. As a rule the acute form of the disease does not appear in males. It was apparently confined to cattle. The disease may be easily differentiated from other similar diseases, such as eczema and vesicular exanthema of cattle. Detailed notes are given on those cases in which observations were made to determine the final history in each case. The economic importance of the disease is considerable on account of the fact that even after recovery heifers or cows are unfit for breeding purposes. A brief bibliography of the subject is appended to the article.

External ulcerative ano-vulvitis, S. T. MILLER (*Amer. Vet. Rev., 26 (1902), No. 4, pp. 326, 327*).—Attention is called to previous reports concerning the existence of this disease. The symptoms as described included a serous exudate, which rapidly produced a brown scab under which fetid pus was formed. The scabs spread rapidly, destroying the underlying tissue. The treatment used was a wash consisting of a strong solution of corrosive sublimate, after which an ointment was applied containing iodoform, oil of eucalyptus, carbolic acid, and petrolatum. This treatment effected a rapid and permanent cure.

Hemorrhagic septicemia, M. H. REYNOLDS (*Amer. Vet. Rev., 26 (1902), No. 9, pp. 819-827, figs. 6*).—The etiology and symptoms of this disease have been carefully investigated and it is believed that many cases of cerebro-spinal meningitis in the East as well as corn-stalk disease in the West should be referred to hemorrhagic septicemia. The symptoms are described in detail. As a rule the temperature is normal or subnormal; local lesions are very limited in extent or wanting; the blood appears to be normal; subcutaneous hemorrhages are common and vary greatly in size; they may appear in almost any part of the subcutaneous tissue, or may even involve the viscera. The disease appears suddenly, develops rapidly, and terminates fatally. During the 2 years in which the disease has been studied in Minnesota 52 outbreaks have occurred, resulting in the death of 551 cattle. Detailed notes are given on some of these outbreaks and descriptions are presented of the pathological anatomy. The source of infection is not yet well understood. Outbreaks have

occurred under circumstances which rendered it impossible to trace the history of infection.

Some diseases incidental to pregnancy and parturition in the cow, A. M. CRICHTON (*Vet. Jour.*, 55 (1902), No. 325, pp. 17-26).—Notes are given on a number of diseases associated with this function, including parturient eclampsia, parturient paresis, abortion, septicemia, metritis, etc.

A deviation from the orthodox method of treating parturient paresis and its etiology, W. E. A. WYMAN (*Jour. Comp. Med. and Vet. Arch.*, 23 (1902), No. 7, pp. 405, 406).—The author discusses the hypotheses which have been formulated as explanation of the etiology of this disease and of the effectiveness of the treatment by means of infusions of iodid of potash. The author rejects the hypothesis of an autointoxication due to metabolic products in the udder as the cause of the disease, and believes that the true cause is to be found in an undue accumulation of nutritive elements in the body of the cow soon after parturition.

Parturient paralysis prior to parturition, J. J. REPP (*Amer. Vet. Rev.*, 26 (1902), No. 6, pp. 545-547).—Notes are given on the symptoms and treatment of a case of this disease which was treated by the author. Sulphate of strychnin was administered, the milk was withdrawn, the udder disinfected, and Schmidt's treatment applied. The treatment, however, in this case was without avail and the case terminated fatally.

Success in the treatment of parturient paresis, W. N. BABCOCK (*Amer. Vet. Rev.*, 26 (1902), No. 7, pp. 635, 636).—A case of this disease, which occurred before parturition, was treated by the author with success. Ergotin was administered every 2 hours and Schmidt's treatment was applied twice. The author states that as a rule he has from 8 to 10 cases of this disease per year, and has not lost a single case in which carbolic acid and glycerin have been added to the usual treatment.

On air treatment of milk fever, K. W. AAKERMAN (*Landtmannen*, 13 (1902), No. 37, pp. 594-597).

Abortion in cows, W. S. PHILLIPS (*Amer. Vet. Rev.*, 26 (1902), No. 5, pp. 431, 432).—An account is given of an outbreak of this disease among a Holstein dairy herd, together with brief notes on the symptoms of the disease in dogs.

Further experiments on the preventive treatment of contagious abortion (*Midland Agr. and Dairy Inst. [Kingston] Rpt. 1901*, pp. 77, 78).—Experiments are being carried out with 3 lines of treatment for contagious abortion. One consists in the internal administration of carbolic acid, the second in the use of antiseptics externally, and the third in a combination of the first and second methods. The sheds and other material which might carry the organism of abortion were carefully washed with lime, and in the first series of experiments pure carbolic acid was administered in doses of 1 fluid gm. for each cow twice a week. In the second series of experiments the posterior parts of the cow were sprayed twice a week with a solution containing 1 part iodo in 80 parts of water. And in the third, these two lines of treatment were combined. The experiments have not as yet been carried on sufficiently to give definite results.

Barrenness of bovines, C. SCHMITT (*Amer. Vet. Rev.*, 26 (1902), No. 7, pp. 624-628).—Notes are given on the various conditions which have been observed as causing sterility in cows. These include stenosis of the cervix, catarrh, and unnatural formation of the cervix.

Note on cirrhosis of the liver in horses and cattle, and its production in the latter experimentally, J. A. GILRUTH (*Veterinarian*, 75 (1902), No. 896, pp. 436-441).—A brief account is presented on the various theories which have prevailed regarding the cause of hepatic cirrhosis. It was shown by experiments that one form of cirrhosis of the liver may be produced as the result of eating *Senecio jacobaeus*. It is believed that what is known as Winton disease and Pictou disease in Nova Scotia are due to the same cause.

Poisoning of cattle by common sorghum and Kafir corn, A. T. PETERS and S. AVERY (*Nebraska Sta. Bul.* 77, pp. 16).—Part of the work reported in this bulletin has already been referred to (*E. S. R.*, 14, p. 298). A chemical study of sorghum and Kafir corn indicates that the prussic acid is not present as such but is set free from a glucosid by an enzym in the plant, or artificially by subjection to boiling water. Experiments made for the purpose of determining the effect of drying upon the presence of prussic acid gave evidence that the prussic acid is dissipated during the process of drying. Antidotes for poisoning by prussic acid mentioned by the authors include glucose, large quantities of milk, and plenty of fresh air. Further studies will be made to determine more definitely the conditions under which prussic acid is formed and also with regard to the effect of drying and the administration of antidotes.

Prussic acid in sorghum, H. B. SLADE (*Jour. Amer. Chem. Soc.*, 25 (1903), No. 1, pp. 55-59).—An outline of the chemical investigations on the poisonous principles of sorghum at the Nebraska Station. In 2 samples of sorghum 0.013 and 0.014 per cent of prussic acid was found. The author notes a great variation in the amount of prussic acid in different samples of sorghum and believes that the acid is produced in the plant by the action of a glucosid.

Phytolacca poison in cattle, G. R. WHITE (*Jour. Comp. Med. and Vet. Arch.*, 23 (1902), No. 7, pp. 439-441).—Five cattle out of a herd of 13 were badly affected with hemorrhagic enteritis accompanied with dysentery. An investigation of this outbreak of disease disclosed the fact that the cattle had eaten large quantities of phytolacca and the author believes that the trouble is to be ascribed to eating this plant.

Report on the mortality among cattle in the Northeastern District, W. T. KENDALL (*Jour. Dept. Agr. Victoria*, 1 (1902), No. 4, pp. 439-441).—A serious outbreak of disease having appeared among cattle, an investigation of the subject was made by the author. It was found that the mortality was about 75 per cent, and that the disease occurred at all seasons of the year but chiefly during the summer months and in dry seasons. Notes are given on the chief symptoms and post-mortem findings. The animals exhibited suspended rumination, inability to swallow, arched back, rough coat, and decrease in the milk flow. It is believed that the disease is due to soil exhaustion. The animals do not obtain sufficient phosphates and other necessary materials from the poor vegetation on the impoverished soils. It is recommended in treating animals thus affected that bone meal, molasses, and linseed oil should be given in the rations, together with phosphate of lime, salts of iron, and potash.

Diseases of sheep, R. A. CRAIG and A. W. BITTING (*Indiana Sta. Bul.* 94, pp. 88, figs. 17).—This bulletin contains brief discussions of the common diseases to which sheep are susceptible and constitutes a sort of handbook of sheep diseases. The various diseases which are discussed are classified according to the organs affected or according to the nature of the parasitic organisms. The subjects discussed are as follows: Diseases of the digestive system, including sore mouth, depraved appetite, tympanites, white scours, jaundice, and peritonitis; diseases of the urinary organs; diseases of the respiratory organs, including catarrh, laryngitis, bronchitis, croupous pneumonia, pleurisy, etc.; diseases of the circulatory system; diseases of the nervous system, including encephalitis, cerebro-spinal meningitis, apoplexy, epilepsy, etc.; diseases of the reproductive system, including abortion, mammitis, etc.; diseases of the eye, and various other infectious or general diseases, such as foot rot, arthritis, malignant edema, rabies, sheep pox, blackleg, tuberculosis, tetanus, influenza, scab, and the diseases caused by lung and stomach worms, tapeworms, flukes, etc.

An experience with nodule disease of sheep, M. H. REYNOLDS (*Amer. Vet. Rev.*, 26 (1902), No. 5, pp. 416-419, fig. 1).—An account is given of an extensive outbreak of this disease among sheep. The symptoms are described and notes are given on the means of preventing the spread of the disease. Treatment is usually of no

avail, as the worms are too well protected on account of their situation in the walls of the intestines.

Anthracid, septic, or blood poisoning diseases of sheep, W. G. DOWLING (*Agr. Gaz. New South Wales*, 13 (1902), No. 11, pp. 1098, 1099).—The symptoms, treatment, and means of preventing malignant edema in sheep are briefly described. The author recommends the immediate treatment of skin wounds received during shearing, and for this purpose solutions of corrosive sublimate or permanganate of potash may be used.

Common colics of the horse, H. C. REEKS (*London: Ballière, Tindall & Cox*, 1903, pp. XII + 224, figs. 8).—In this volume the author has compiled and digested the available literature on the subject of colic in horses. To this is added material which the author has accumulated during his own practice. The following subjects are discussed; Definition and classification of colic, surgical anatomy of the abdomen, examination of patients, etiology of colic, gastric impaction, gastric tympany, rupture of the stomach, obstruction of the colon, obstruction of the small intestines, intestinal irrigation in obstructions of the colon, surgical treatment of intestinal obstructions, intestinal tympany, enteritis, superpurgation, and the treatment of colic in young animals.

Equine tropical diseases, particularly ulcerative lymphangitis, C. NOCKOLDS (*Amer. Vet. Rev.*, 26 (1902), No. 8, pp. 756-763).—Brief notes are given on a number of diseases commonly observed in the Philippine Islands. These include colic, pneumonia, founder, thrush, tetanus, glanders, anthrax, rinderpest, and ulcerative lymphangitis. Tetanus seems to be very prevalent at present in the Philippines. Special attention is given to ulcerative lymphangitis. This is described as a specific infectious disease characterized by lesions in the lymphatics and the formation of multiple abscesses in affected parts. The death rate is about 15 per cent. The hind limbs are most commonly affected. The animal becomes emaciated and the disease may run an acute or chronic course. It may be differentiated from glanders by the absence of ulcers and by various other symptoms which are described in detail. The bacteriology of the subject is not yet completed. Some success has been had in treating the disease with iodid of potash, iron, antiseptics, and actual cautery upon the ulcers. Hyposulphite of soda also promises good results.

Pneumonia in the horse: Its etiology, J. A. W. DOLLAR (*Veterinarian*, 75 (1902), No. 866, pp. 395-409).—The author presents a general account of this disease from a digest of the literature of the subject and from personal experience. The various forms under which the disease occurs are described, and notes are given on the bacteriology of the disease.

Pneumonia and its treatment, J. D. FAIR (*Amer. Vet. Rev.*, 26 (1902), No. 5, pp. 425-430).—Brief notes are given on the diagnosis, symptoms, and treatment of pneumonia in horses.

The pathogenesis of equine pneumonic emphysema, A. H. BAKER (*Jour. Comp. Med. and Vet. Arch.*, 23 (1902), No. 9, pp. 562-565).—The origin of this disease is believed to be found in 99 per cent of the cases in faulty dietetics. Gastric disturbances appear in nearly all cases. The author believes that the disease is produced by continued and excessive feeding with over-ripe hay, particularly timothy and red clover. As a means of preventing the disease the author recommends giving suitable grain ration in order to check the tendency of horses to eat too much hay.

Materials for a clinical diagnosis and pathological histology of acute nephritis in horses and dogs, M. P. RUKHLYADEV (*Uchen. Zapiski Kazan. Vet. Inst.*, 19 (1902), Nos. 2, pp. 71-110; 3, pp. 133-152).—A detailed discussion is given on the causes, symptoms, and treatment of this disease. Especial attention is directed to the clinical diagnosis and pathological histology presented during the

course of the disease. The literature of the subject is critically discussed in connection with the investigations of the author.

Traumatic peritonitis, with symptoms of anthrax, A. S. ZHIRNOV (*Arch. Vet. Nauk, St. Petersburg, 32 (1902), No. 9, pp. 797-799*).—Brief notes are given on the course of this disease in horses in certain cases which presented symptoms similar to those of anthrax. Attention is called to the means of arriving at a satisfactory diagnosis in such cases.

Glanders, W. HUNTING (*Veterinarian, 75 (1902), No. 896, pp. 409-436*).—The author presents a statistical account of the distribution of glanders and of the extent of losses due to this disease in Great Britain for a number of years. Notes are given on the relative prevalence of the disease in different months and on the methods by which it is spread. The author discusses also the cause, modes of infection, period of incubation, symptoms, diagnosis, post-mortem lesions, and the use of mallein in testing horses. The conclusions which the author draws from his study of glanders are as follows: Notification by the owner of glandered animals should be made either to the veterinary inspector or police authorities. Horses which have been exposed to contagion should be suspected and treated accordingly. Horses which have reacted to the mallein test should be quarantined. All animals which show clinical symptoms of glanders should be slaughtered. Compensation for slaughtered horses should be one-fourth their value. Compensation for horses slaughtered solely on account of reaction to mallein should be one-half their value.

Communicability of glanders and the action of mallein, A. C. COPE ET AL. (*Bd. Agr. [London], Rpt. Dept. Com. on Glanders, 1902, pp. 22*).—The experiments reported in this paper were undertaken to determine 2 points in connection with the study of glanders, viz, whether a healthy horse which reacts to mallein may spread the infection to other horses, and whether an apparently healthy horse which has once reacted and subsequently ceases to react is infectious. In experiments bearing on the first point 16 horses were used, and during this test it was found that healthy horses kept in association with reacting horses contracted glanders. It is concluded, therefore, that reacting animals, although without clinical symptoms, are capable of spreading the disease. Other experiments were conducted with horses which had ceased to react to glanders, and in these tests the results were negative in every case. It is concluded, therefore, that such animals are not capable of spreading the infection of glanders.

The persistence of the virulence of glanders bacilli upon artificial nutrient media, I. SHANTZIR (*Arch. Vet. Nauk, St. Petersburg, 32 (1902), No. 10, pp. 833-838*).—Experiments were made in keeping glanders bacilli in cultures upon potatoes, agar, glycerin-bouillon, and meat-peptone-glycerin-gelatin. Glanders bacilli cultivated on potatoes were found to have lost their virulence, as determined by inoculation experiments, after 4 months. The results of experiments with glanders bacilli on other nutrient media indicate that the organism may remain virulent for 5 months in the bouillon and for 5 to 7 months in the gelatin. Inoculations made with material kept for these periods killed guinea pigs within from 7 to 13 days. The author believes that these facts may not only be of theoretical importance, but may also have a bearing on veterinary sanitation, since the glanders bacillus may persist in a virulent condition for a considerable period outside of the animal body.

Inoculation of frogs with glanders, I. SHANTZIR (*Arch. Vet. Nauk, St. Petersburg, 32 (1902), No. 9, pp. 765-781*).—The literature of this subject is critically reviewed in connection with a discussion of the author's own investigations. It was found that the glanders bacillus retained its virulence for a period of at least 68 days within cold-blooded animals like the frog. The glanders bacillus was found in the blood of hogs within from 12 to 28 days after inoculation.

Differential diagnosis between bursattee, furunculus, and farcy, C. C. LYFORD (*Amer. Vet. Rev., 26 (1902), No. 9, pp. 845-849*).—Bursattee appears to be

an epithelial disease and makes its appearance on the surface of the body. It is a warm weather disease and prevails most extensively during wet seasons. Farcy usually affects the lymphatic system and may therefore be superficial or deep. The discharge from farcy abscesses is extremely cohesive. Furunculus usually appears below the fetlock and affects the coronary band. It is ushered in with a chill and the subsequent temperature varies from 105 to 107°. The most successful treatment for bursattee in the author's experiments was blistering with a mixture of cantharides and biniodid of mercury repeated every 2 or 3 days.

Epizootic abortion in mares, J. GUILLEREY (*Arch. Wiss. u. Prakt. Thierh.*, 29 (1903), No. 1-2, pp. 37-63, figs. 4).—The literature of this subject is critically discussed in connection with a bibliography. The author made careful observations on a large number of cases and the usual symptoms are described, together with the more common complications. Special attention is given to the period of incubation, means of dissemination, etiology, and treatment. In preventing the persistence and spread of this disease it is considered absolutely necessary to employ the most rigid antiseptic treatment to all infected animals.

Nagana and mal de caderas as two distinct diseases, A. LAVERAN and F. MESNIL (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 20, pp. 838-840).—According to the authors' opinions these 2 diseases are distinct, for the following reasons: There are constant morphological differences between *Trypanosoma brucei* and *T. equinum*; animals immunized against nagana are still susceptible to mal de caderas; and the serum of animals immunized against nagana is not active toward *T. equinum*.

Investigations on the treatment and prevention of nagana, A. LAVERAN and F. MESNIL (*Ann. Inst. Pasteur*, 16 (1902), No. 11, pp. 785-817).—A historical account of previous investigations on this subject is presented, in connection with a critical review of the literature relating to nagana. The chief objects of the authors' experiments were to test the problem of treating nagana with chemical products or with sera, including human serum and the serum of animals which had been rendered immune to nagana. The experiments also included attempts to immunize animals against the disease. A considerable number of chemical substances were experimented with for determining their value in the treatment of the disease. As a result of these experiments it was found that arsenious acid and human serum are the only substances which possess any great value in the treatment of nagana. Arsenious acid was found to prolong the life of affected animals. The animals treated with this chemical, however, did not always recover, and in some instances served as a source of infection for healthy animals. Human serum was found to produce a complete recovery in mice. The treatment of large animals, however, by this method is impractical on account of the large doses of serum which are required.

Statistics as to the color of surra victims, C. NICKOLDS (*Amer. Vet. Rev.*, 26 (1902), No. 9, pp. 850-854).—Observations on the appearance of surra in the Philippine Islands indicate that mules are more susceptible to this disease than horses and that light colored animals are attacked more frequently than dark colored animals.

Notes on the tsetse fly and the surra disease in German East Africa, F. STUHLMANN (*Ber. Land u. Forstw. Deutsch-Ostafrika*, 1 (1902), No. 2, pp. 137-153, pl. 1, figs. 4).—The author gives an account of investigations which he made regarding surra in various parts of German East Africa. Especial attention is given to a detailed description of the tsetse fly in all its stages and brief notes are also presented on certain related species, such as *Stomoxys calcitrans*.

The occurrence of *Glossina tabaniformis* in Dar-es-Salaam, F. STUHLMANN (*Ber. Land u. Forstw. Deutsch-Ostafrika*, 1 (1902), No. 2, pp. 173-175, fig. 1).—The insect is described in detail and the measurements of its various anatomical structures are compared with those of the tsetse fly. The question is raised whether this species may also be instrumental in carrying surra. It appears from observations thus far made that this is not the case.

Notes on a feeding experiment to produce leucoencephalitis in a horse, with positive results, T. BUTLER (*Jour. Comp. Med. and Vet.*, 23 (1902), No. 8, pp. 498-501).—An outbreak of this disease in an acute form occurred near Wakefield, Kans., in 1901. From an examination of the conditions surrounding this outbreak it appeared that the disease was due to the use of moldy corn. An experiment was made in feeding samples of this corn to 2 colts. One of the colts died after about 3 weeks, and a post-mortem examination showed that the white substance of the cerebrum was much softened and broken down. This condition corresponds to those found in spontaneous cases of the disease.

The duration of the presence of the plague organism when injected into the veins of the horse, CAROUGEAU (*Ann. Inst. Pasteur*, 16 (1902), No. 11, pp. 842-852).—The author's experiments on this subject indicate that the cultivation of the organism of the plague at a high temperature or its passage through a horse may operate as a means of differentiating the more virulent forms of the bacillus. The less virulent bacilli are more easily destroyed by heat or by phagocytes in the horse than are the more virulent forms.

Cattle plague in camels, CHEGIS (*Arch. Vet. Nauk, St. Petersburg*, 32 (1902), No. 10, pp. 882, 883).—An investigation of this disease among camels showed that under certain conditions these animals may be seriously affected. The period of incubation was found to be 7 days. The disease begins with a fever and is characterized by continued high temperature, weakness, and erosions upon the mucous membranes of the mouth. The course of the disease is about 14 days and the death rate among camels appears to be about 5 per cent.

Canine distemper, F. T. G. HOBDAV (*Veterinarian*, 75 (1902), No. 897, pp. 482-489).—A number of experiments were conducted to test the value of vaccination in the prevention of distemper in dogs. It was found that 6 puppies after vaccination were quite as susceptible to distemper as other puppies which had not been vaccinated, and the distemper was as severe in the vaccinated as in the nonvaccinated animals. This method of treatment therefore appears to have little or no value.

Rabies and dog distemper, BECK (*Arch. Wiss. u. Prakt. Thierh.*, 28 (1902), No. 5, pp. 505-509).—A careful study of a number of cases of rabies and dog distemper disclosed the fact that in doubtful cases a differential diagnosis may be reached by inoculation of rabbits; while both diseases may be communicated to rabbits, it is impossible to reproduce dog distemper by inoculation of other animals with the brain of affected rabbits. This point is considered to be of much importance in differentiating between the 2 diseases.

Fowl sickness, J. F. MARSHALL (*Agr. Jour. and Min. Rec. [Natal]*, 5 (1902), No. 18, pp. 565-567).—Fowl sickness, or enteritis, is said to have broken out in many localities in Natal. Notes are given on the symptoms, post-mortem findings, and means of combating this disease.

Trichophytosis, J. B. KESSLER (*Jour. Amer. Med. Assoc.*, 39 (1902), No. 17, pp. 1050, 1051).—Attention is called to the prevalence of ringworm disease among various animals, especially in cattle, and the danger of transmission to man. A considerable proportion of the outbreaks of so-called barbers' itch is believed to be directly attributable to the prevalence of this disease in a mild form among calves.

Mange, S. B. WOOLLATT (*Agr. Jour. and Min. Rec. [Natal]*, 5 (1902), No. 17, pp. 533-537).—The author discusses the various forms of mange, including sarcoptic, dermatodectic, and symbiotic. Notes are given on the animals affected with these different kinds of mange and on the results of the attack of the disease upon different animals. In the treatment of mange it is recommended that the scabs or crusts be removed by substances which readily dissolve such material, and that antiseptic dressings of various sorts be then applied to the infested areas. Among the various mange dressings discussed, mention may be made of the following: Kerosene emulsion dip, containing hard soap, water, and kerosene; lime and sulphur dip; tobacco

and sulphur dip; and a dip containing $\frac{1}{2}$ oz. arsenic, 1 lb. soft soap, 2 oz. washing soda, 4 oz. Stockholm tar, and 2 gals. water.

A note on various pasteurelloses observed in Turkey, M. NICOLLE (*Ann. Inst. Pasteur*, 16 (1902), No. 10, pp. 775-778).—Brief notes are given on pneumonia of goats, fowl cholera, and the forms of pasteurelloses observed in rabbits, guinea pigs, horses, sheep, and dogs.

Animal parasites, A. A. BROWN (*Jour. Dept. Agr. Victoria*, 1 (1902), Nos. 4, pp. 409-412; 5, pp. 522-524, pl. 1; 6, pp. 613-615, pls. 5; 7, pp. 698-700, pl. 1).—Notes are given on the life history and injuries due to infestation with *Tænia echinococcus*, *T. solium*, *T. expansa*, and tapeworms of the horse, cat, fowls, and man. The author discusses the alternation of generations in these worms, with special reference to the transmission of the immature form to the definite host. Suggestions are also made regarding the use of vermifuges for expelling the adult tapeworm from the intestines and also with regard to preventive measures to be adopted in checking the distribution of the species concerned.

AGRICULTURAL ENGINEERING.

Engineering for land drainage, C. G. ELLIOTT (*New York: John Wiley & Sons; London: Chapman & Hall, Ltd.*, 1903, pp. VII+232, pls. 6, figs. 41).—This is "a manual for laying out and constructing drains for the improvement of agricultural lands," in which the purpose of the author has been "to emphasize and make clear those points which the student, the busy agriculturist, and the practical engineer should know. . . . It puts the experience and practice of years into a form which will be available to others who wish to quickly acquire the principles and practice of land drainage." Different chapters deal with soils, land drainage practice, leveling and topography, laying out drains in the field, fixing the grade of drains, maps and records, grading the ditches for tile, flow of water through pipes, size of lateral drains, open drains, drainage of barnyards, cattle lanes, etc., road drainage, drainage districts, estimates of cost, and benefits and profits of land drainage.

Irrigation institutions, E. MEAD (*New York and London: The Macmillan Company*, 1903, pp. XI+392, figs. 6).—This work, by the Chief of Irrigation Investigations of this Office, "is based on 20 years' experience in the development of irrigated agriculture in the arid West" as engineer in charge of irrigation works, administrator of irrigation laws, and teacher and investigator of the subject of irrigation. It contains chapters on land laws of the arid region, the beginnings of irrigation, the doctrine of appropriation, contract water rights, measurement of water, the duty of water, irrigation in Colorado, California, Utah, Wyoming, and in the other arid and semi-arid States, riparian and interstate rights, and methods and measures needed for future development.

Hydrography (*Twenty-second Ann. Rpt. U. S. Geol. Survey, 1900-1901, pt. 4, pp. 690, pls. 65, figs. 244*).—This includes reports by F. H. Newell of progress of stream measurements in 1900 (see also E. S. R., 13, p. 1102); by A. P. Davis on the hydrography of the American isthmus; and by W. D. Johnson on the High Plains and their utilization. The last paper gives a summary of an earlier article on the same subject (E. S. R., 13, p. 1000) and discusses the underground supply of water and its utilization in irrigating the valleys, the uplands being utilized mainly for stock farming.

Water storage on Salt River, Arizona, A. P. DAVIS (*Water Supply and Irrig. Papers, U. S. Geol. Survey, No. 73, pp. 54, pls. 25, figs. 4*).—This paper gives the results of surveys and investigations for water storage on Salt and Verde rivers during 1901. It is of especial interest as giving in considerable detail plans and specifications for the Salt River reservoir at the junction of Tonto Creek with Salt River, which is to be one of the first of the large projects undertaken under the recently enacted

national water storage law. The paper also contains similar data for a reservoir at Camp McDowell on the Verde River, and detailed information regarding the water supply of the Salt and Verde River drainage basins.

Water resources of the State of Colorado, A. L. FELLOWS (*Water Supply and Irrig. Papers, U. S. Geol. Survey, No. 74, pp. 151, pls. 14, figs. 5*).—This paper deals with drainage and stream measurements in the South Platte, Arkansas River, Rio Grande, San Juan, Grand River, and Green River irrigation divisions of Colorado, and gives a very complete compilation of hydrographic data for the State.

Report of progress of stream measurements for the calendar year 1901, F. H. NEWELL (*Water Supply and Irrig. Papers, U. S. Geol. Survey, No. 75, pp. 246, pls. 13, figs. 71*).—This is the third part of the report on this subject, the first two parts being issued as Water Supply and Irrigation Papers Nos. 65 and 66 (E. S. R., 14, p. 615).

Observations on the flow of rivers in the vicinity of New York City, H. A. PRESSEY (*Water Supply and Irrig. Papers, U. S. Geol. Survey, No. 76, pp. 108, pls. 13, figs. 8*).

Colonization and irrigation in Uganda and the British East Africa Protectorate (*Jour. Soc. Arts, 50 (1902), No. 2605, pp. 896, 897*).—This is an abstract of a paper read by R. B. Buckley at the recent meeting of the British association at Belfast, dealing with climatic conditions and possibilities of irrigation from surface and underground waters.

Irrigating pumping plant, A. W. CLAPP (*Irrig. Age, 18 (1903), No. 5, pp. 134-136, figs. 4*).—Description of a pumping plant for lifting water from Utah Lake into Jordan River.

The limit of use of hand pumps, M. RINGELMANN (*Jour. Agr. Prat., n. ser., 5 (1903), No. 8, p. 260*).—A 20-meter lift is considered the practical limit for such pumps.

On a leaf arrester or apparatus for removing leaves, etc., from a water supply, THE EARL OF ROSSE (*Rpt. British Assoc. Adv. Sci. 1901, pp. 769, 770*).—"The apparatus consists of a cylinder of wire gauze, of 4 ft. diameter and $4\frac{1}{2}$ ft. height, set in an opening in a vertical diaphragm extending across the supply drain and revolving twice in a minute or so round a vertical axis. The current flows through the gauze cylinder in a horizontal direction. The leaves, carried down with the current, attach themselves under pressure of the stream, are carried round till they reach the diaphragm, which on that side is double, with an intervening space of some 10 in., which is connected with the tail-race; and at this point, the current through the gauze being reversed, the leaves are detached and are carried by a portion of the water toward the tail-race. Four or five per cent of the supply is ample for conveying the leaves; probably much less would suffice. A very few leaves get past and onto the screen, but so few that they give no trouble." A disk form of the same apparatus is also described.

Investigations on agricultural machinery by the Bavarian Machine Testing Station of Weihenstephan, H. PUCHNER (*Untersuchungen auf dem Gebiete des landwirtschaftlichen Maschinenwesens ausgeführt von der königlichen bayerischen Maschinenprüfungsstation Weihenstephan. Munich: C. A. Seyfried & Co., 1903, pp. 215, figs. 96*).—This report gives a brief history of the organization and development of this station and summarizes the results of trials of various kinds of agricultural machinery conducted during the period from 1897-1902.

The Danish trials of agricultural machinery, E. JØRGENSEN (*De danske Redskabs og Maskinprøver. Copenhagen, 1902, pp. 199*).—The trials cover the period from 1872 to 1901. They were conducted under the auspices of the Royal Agricultural Society of Denmark by a permanent committee of the society, appointed to conduct the trials. Reports of the trials have been published in the agricultural press from

time to time. A separate chapter is devoted to an account of trials of agricultural machinery in Sweden, Norway, and Germany.—F. W. WOLL.

The machine-testing station at Paris, M. RINGELMANN (*Ann. Inst. Nat. Agron.*, 2. ser., 1 (1876-1901), pp. 527-536, fig. 1).—A brief account of the organization, development, equipment, and work of this station, which was established in 1888.

History of the development of the plow during 5,000 years, A. LAACKE (*Deut. Landw. Presse*, 30 (1903), No. 17, pp. 135-138, figs. 21).—A brief summary of the main steps in the development of the plow.

Practical experience in the use of grain-seeding machines, TRÜBENBACH (*Fühling's Landw. Ztg.*, 51 (1902) Nos. 19, pp. 718-723; 20, pp. 742-750).

Exhibit of mowers and reapers at Hasselt in 1901, J. PYRO (*L'Ing. Agr. Gembloux*, 13 (1902), No. 5, pp. 187-203).—Some of the special features of the different machines are described and tests of draft are reported.

Historic highways of America, A. B. HULBERT (*Cleveland, Ohio: Arthur H. Clark Co.*, 1902, vols. 1, pp. 140, figs. 4; 2, pp. 152, pls. 3, maps 3; 1903, vol. 3, pp. 215, pls. 5, maps 2).—This is the first three of the proposed series of ten volumes on this subject. Volume 1 deals with the paths of the mound-building Indians and great game animals; volume 2, Indian thoroughfares; and volume 3, Washington's road (Nemacolin's path), the first chapter of the old French war. The book describes these historic highways and discusses in a very interesting way their relation to national development.

Proceedings of the North Carolina Good Roads Convention, held at Raleigh, N. C., February 12 and 13, 1902, J. A. HOLMES (*U. S. Dept. Agr., Office of Public Road Inquiries Bul.* 24, pp. 72, pls. 5).—Among the subjects discussed are: Interest of Railroads in Road Improvement, by M. A. Hays; Progress of the Good Roads Movement in the United States, by M. Dodge; Practical Suggestions as to Ways and Means, by M. C. Butler; History of Road Making in Mecklenburg County, by S. B. Alexander; Good Roads and their Relation to the Farmer, by T. B. Parker; Economical Roads for Rural Districts, by W. C. Riddick; Good Roads and their Relation to Country Life, by W. R. Cox; Roads and Road Laws of Wake County, by W. C. McMackin; Good Roads and their Relation to Churches, by T. N. Ivey; The Good Roads Movement in the West, by J. W. Abbott; Economy of Good Roads, by G. T. Winston; Good Roads and their Relation to the Postal Service, by E. W. Pou; Rural Free Delivery of Mails, by A. W. Machen; Methods of Raising and Expending Road Funds, by F. M. Simmons; and Road Building in North Carolina, by J. A. Holmes.

Ninth annual report of the commissioner of public roads for the year ending October 31, 1902, H. I. BUDD (*Trenton, N. J.: The John L. Murphy Pub. Co.*, 1902, pp. 243, pls. 29, figs. 2, map 1).—This report contains a detailed statement of cost, and descriptions of roads improved in 1902; and papers and compiled information regarding various phases of road building.

The protection of buildings from lightning, K. HEDGES (*Rpt. British Assoc. Adv. Sci.*, 1901, pp. 770, 771).—The author compares continental and American methods, and describes the plans devised by him for the protection of St. Paul's Cathedral and Westminster Abbey as illustrating his views in general on this subject.

MISCELLANEOUS.

Fifteenth Annual Report of Alabama College Station, 1902 (*Alabama College Sta. Rpt.* 1902, pp. 35).—This includes the organization list of the station, a financial statement for the fiscal year ended June 30, 1902, and reports of the president and acting director, chemist, associate chemist, veterinarian, agriculturist, and biologist and horticulturist reviewing the different lines of station work during the year. Summaries of Bulletins 118-121 of the station are also included.

Biennial Report of Missouri Fruit Station, 1901-2 (*Missouri Fruit Sta. Rpt. 1901-2, pp. 39, pls. 4*).—The work of this station during the two years is outlined at some length and a detailed financial statement is given.

Annual Report of Nevada Station, 1902 (*Nevada Sta. Rpt. 1902, pp. 30, pls. 5*).—This includes a brief report of the board of control, a general review of station work during the year by the director, departmental reports, and a financial statement for the fiscal year ended June 30, 1902.

Thirteenth Annual Report of New Mexico Station, 1902 (*New Mexico Sta. Rpt. 1902, pp. 31*).—This includes the organization list of the station; a report of the director on the station staff, lines of investigation, publications, and exchanges; reports of the heads of departments; and a financial statement for the fiscal year ended June 30, 1902. A detailed outline of experiments is included in the report of the director and some of the results of the station work are briefly noted in the departmental reports.

The agricultural experiment station of Porto Rico; its establishment, location, and purpose, F. D. GARDNER (*Porto Rico Sta. Bul. 1, pp. 14, pls. 4*).—This contains an account of the establishment of the station under the auspices of this Office, a description of its location and equipment, an outline of contemplated work, and a statement as to the purpose of the station. This bulletin is published in both English and Spanish.

Annual Report of Virginia Station, 1902 (*Virginia Sta. Rpt. 1902, pp. 15*).—This contains the organization list of the station, a financial statement for the fiscal year ended June 30, 1902, and brief reports of the director and heads of departments.

Organization lists of the agricultural colleges and experiment stations in the United States (*U. S. Dept. Agr., Office of Experiment Stations Bul. 122, pp. 96*).

Experiment Station Work, XXI (*U. S. Dept. Agr., Farmers' Bul. 162, pp. 32, figs. 3*).—This number contains articles on the following subjects: The value of barnyard manure, nitrate of soda for market garden crops, cooking meat, feeding value of sugar-beet products, some recent experiments in horse feeding, poisoning of horses by the field horsetail, fattening beef for the market, difference in profit from dairy cows, effect of shearing on the gains made by lambs, soft pork and bacon, purifying milk by centrifugal separation, cheese prints, influence of the height of wheel on the draft of farm wagons, and the disk plow.

Reports of the farmers' institutes, live stock associations, and the dairy association of Manitoba for 1901 and 1902 (*Winnipeg, Manitoba: Dept. Agr. and Immigration, 1902, pp. 226*).

Annual agricultural statistics of France, 1901 (*Ann. Min. Agr. [France], 21 (1902), No. 3, pp. 494-788*).—Agricultural statistics of France for 1901, including crops, live stock, imports and exports, etc.

Austrian field crop statistics for 1902 (*Separate from Statist. Monatschr., Vienna, 1903, pp. 12, dgm. 5*).—The yields of wheat, rye, barley, oats, and corn for the different provinces are given in tables.

Norwegian agriculture during recent years, J. SMITT (*Larsber. Offent. Foranstalt. Landbr. Fremme, 1901, pp. 1-75*).

Agriculture of the native Javanese, H. C. H. DE BIE (*Meded. 'S Lands Plantentuin, 1902, No. 58, pp. XXXIV + 107*).—This publication presents the agricultural conditions on the island of Java and describes the agricultural methods practiced by the natives. The culture of all important field and garden crops grown by the native Javanese is discussed.

Agricultural education in Cape Colony (*Agr. Jour. Cape Good Hope, 22 (1903), No. 1, pp. 17-24, pls. 5*).—An account is given of the agricultural school at Elsenburg and of its work.

Accessions to the Department Library, 1902 (*U. S. Dept. Agr., Library Buls. 40, pp. 67; 43, pp. 37; 44, pp. 51; 45, pp. 72*).

NOTES.

CALIFORNIA UNIVERSITY AND STATION.—The university has received from the State legislature the following special appropriations: Two hundred and fifty thousand dollars for the erection of a new building on the campus, to conform to the Hearst-Benard plans for the new university; \$12,000 for farmers' institute work for the next two years; \$3,000 for viticultural investigations; and \$5,000 for the establishment of a poultry experiment station at Petaluma. The poultry station is to be under the supervision of the director of the State station, and its objects, as set forth in the act of establishment, are "the study of the diseases of poultry, to ascertain the causes of such diseases and to recommend treatment for the prevention and cure of the same; to ascertain the relative value of poultry foods for the production of flesh, fat, eggs, and feathers; to recommend methods of sanitation; and to conduct investigations for the purpose of securing results conducive to the promotion of the poultry interests of the State." A fertilizer-control law has also been passed, providing \$1,000 for laboratory equipment, and a revenue derived from license tax from which all expenses are to be paid. The station will have charge of the work.

COLORADO COLLEGE AND STATION.—The State legislature has made an appropriation of \$40,000 for the construction of a building for the department of civil and irrigation engineering. The building will also contain the office of the director of the station.

DELAWARE COLLEGE.—The legislature recently adjourned appropriated \$15,000 for the college to cover the biennial period. Of this amount, \$6,500 is to be used for repairs and additions to the buildings made some time since, about \$6,500 for the erection of an addition to the workshop, and \$2,000 for increasing the facilities for teaching agriculture.

FLORIDA STATION.—G. F. Mitchell, assistant in field experiments, has resigned to accept a position in South Carolina.

IDAHO STATION.—The State legislature has appropriated \$3,000 for live stock and \$2,000 for fences and repairs for the station.

IOWA COLLEGE AND STATION.—Contracts have been let for the construction of a farm mechanics building, 60 by 100 feet and 1½ stories in height, at a cost of \$35,000; a 2-story judging pavilion for agronomy and animal-husbandry work, at \$12,000, and additional greenhouses for the departments of agronomy, soils, and horticulture, at \$8,000. The courses of study have been revised and strengthened so as to include complete four-year courses in animal husbandry, agronomy, horticulture, and dairying.

KANSAS COLLEGE AND STATION.—The State legislature has made a total appropriation of \$240,260 for the college for buildings and maintenance during the next two years. Of this amount \$15,000 is for the erection and equipment of a creamery building. Provision is made for an addition to the shops at a cost of \$5,000; \$10,500 is appropriated for the purchase of additional land, and \$10,000 for a water plant. The department of animal husbandry receives \$5,000, the agricultural department

(agronomy) \$2,000, the horticultural department \$1,500, and the farmers' institutes \$2,000 a year for the biennial period in each case. The legislature also directed that a tuition fee of \$3 per term, designated as an "incidental fee," be required of students residing within the State, and a matriculation fee of \$10 and an "incidental fee" of \$10 per annum of students from without the State. A total of \$32,550 was appropriated for the substation at Fort Hays, making liberal provision for equipment and work. Among the items mentioned in the act are a dwelling house, horse barns, cattle sheds and yards, bridges, fences, a water plant, a skimming station, tools and implements, teams, and live-stock experiments. The appropriation for the substation also includes \$1,000 for irrigation investigations in cooperation with this Department. The governing board of the college and station is at present constituted as follows: J. S. McDowell, of Smith Center, president; C. E. Friend, of Soldier, vice-president; E. T. Fairchild, of Ellsworth, treasurer; R. J. Brock, of Manhattan; J. W. Berry, of Jewell City; J. O. Tulloss, of Sedan; and E. R. Nichols, of Manhattan, secretary ex officio.

MASSACHUSETTS STATION.—Daniel L. Cleaves, assistant chemist, is no longer connected with the station.

MISSOURI FRUIT STATION.—Paul Evans, a graduate of the State University, has been elected director of the station.

NEBRASKA UNIVERSITY AND STATION.—The State legislature at its recent session appropriated \$15,000 for the establishment and maintenance for two years of a substation in the western portion of the State. The work at first will be directed mainly to the protection and improvement of pasture lands. An appropriation of \$100,000 was also made for buildings and improvements for the school of agriculture and experiment station, mainly for the purpose of facilitating agricultural instruction.

NEW HAMPSHIRE COLLEGE AND STATION.—C. M. Weed will have charge of nature study and elementary science courses at the session of the Marthas Vineyard Summer Institute, to be held at Cottage City, Mass., during the five weeks beginning July 14.

NEW JERSEY STATION.—The experiment station building was completely destroyed by fire on April 23. A large proportion of the records and collections was saved. The total loss was about \$25,000, practically covered by insurance.

OHIO STATION.—A. D. Selby, botanist of the station, has been granted a research scholarship in the New York Botanical Garden, where he has been working since December.

TENNESSEE STATION.—The State assembly which has just adjourned appropriated \$10,000 for the purchase of additional land for the station, and increased the appropriation for farmers' institutes to \$5,000. The station will hereafter have charge of the fertilizer inspection work, which will probably add \$3,000 to the income of the station.

UTAH STATION.—The State legislature recently adjourned made the following appropriations for the station for the two years 1903 and 1904: General maintenance, \$750; printing, \$2,000; building for poultry, \$3,500; thrasher with power, \$400; completion of cattle and sheep barns, \$2,700; building for hogs, \$1,500; pure-bred sheep and hogs, \$800. An appropriation of \$12,500 was also made for the establishment and maintenance for two years of five experiment farms to be located in different sections of the State for the purpose of testing the possibilities of the nonirrigable lands.

U. S. DEPARTMENT OF AGRICULTURE.—Dr. H. W. Wiley, chief of the Bureau of Chemistry, has been appointed official representative of the United States to the Fifth International Congress of Applied Chemistry, to be held in Berlin, May 31, 1903. W. H. Krug, formerly in charge of the dendro-chemical laboratory of the Bureau of Chemistry, has resigned to accept a position with A. Klipstein & Co., of New York.

H. L. Bolley, botanist of the North Dakota College and Station, has been appointed agricultural explorer of the Bureau of Plant Industry, the appointment to take effect June 1, 1903. He will visit different countries of Europe, particularly Russia, for the purpose of securing seeds of desirable varieties of flax. One of the principal objects will be to obtain varieties resistant to the flax wilt, due to a species of *Fusarium*, which disease has been under investigation by Professor Bolley for a number of years.

J. R. Stewart, laboratory assistant in the pathological division of the Bureau of Animal Industry, leaves May 1 to accept a position with the National Vaccine Company.

H. E. Williams has been promoted to assistant chief of the Weather Bureau, D. J. Carroll to chief clerk, and E. B. Calvert to chief of division, the appointments to take effect July 1.

G. K. Holmes, statistical expert of the Division of Statistics, has been made chief of the Division of Foreign Markets.

MISCELLANEOUS.—The North Carolina Agricultural and Mechanical College announces a summer school for teachers, to open July 1 and close July 31. Six courses of study are announced, as follows: (1) Elementary agriculture, (2) manual training, (3) nature study, (4) public school branches and kindergarten work, (5) literary subjects, and (6) Sunday-school instruction.

Andrew Carnegie has given \$600,000 toward the endowment of the Tuskegee Normal and Industrial Institute.

The Agricultural Experimenters' League has recently been organized in New York "for the promotion of cooperative experiments in the various departments of farm husbandry; for the promotion of intercourse among those studying farm problems; for the advancement of agricultural education; for the collection and dissemination of data relating to country life, and for the purpose of supporting legislation favorable to the promotion of these objects." The active president of the league is James E. Rice, of Yorktown, N. Y., and the secretary, John Craig, of Cornell University.

A general index to the reports and bulletins of the Canada Experimental Farms published from 1887 to 1901 has recently been issued. The index is detailed and complete, and will be very useful in making readily accessible the results of the extended work which has been done on varieties of field crops, fruits, and vegetables, and along other lines.

Floral Life is the name of a new monthly magazine published in Philadelphia, and devoted to nature, horticulture, floriculture, and ornamental gardening. The magazine is in reality a continuation of *Meehan's Monthly*, which has been considerably enlarged and greatly improved in appearance by the use of many half-tone reproductions.

T. H. Schloesing, jr., has been elected a member of the Paris Academy of Sciences in the section of agriculture, in the place of the late P. P. Dehérain.

The death of Prof. Augusto Napoleone Berlese, which took place at Milan, January 26, 1903, is noted in *Staz. Sper. Agr. Ital.*, 36 (1903), No. 1, p. 33. Professor Berlese was born in October, 1864, and received his doctor's degree from the faculty of science in 1885. His principal works, a list of which is given, have been conducted along the lines of vegetable pathology.

EXPERIMENT STATION RECORD.

VOL. XIV.

JUNE, 1903.

No. 10.

During the past few years there has been a rapid growth of interest in questions relating to courses in agriculture of secondary grade. This has been due to several causes operating at the same time. The faculties and equipment of the agricultural colleges have been very materially strengthened, the number and variety of their courses in agriculture have been greatly increased, and they are engaging much more largely in various forms of university-extension work through the farmers' institutes, correspondence courses, etc., thus attracting a larger number of students. But this development of the agricultural colleges has only served to bring out more clearly the fact that under the best conditions, if they are to maintain their standing as colleges, they can meet the educational requirements of only a small fraction of the youth on our farms. If any considerable body of the farm boys and girls are to receive definite instruction in the principles of agriculture, it must be in schools of lower grade than the colleges.

In the elementary schools no considerable amount of agricultural instruction can ever be included. Without doubt their courses of study can be much improved so as to inculcate a love of nature and country life and to impart many facts and a few principles which will be of direct and lasting benefit to the young people who will go out from them to spend their lives on farms, but in schools of this low grade it will never be possible to teach the sciences related to agriculture or to give any systematic instruction in the theory and practice of agriculture. For these reasons the friends of agricultural education are now turning their attention more and more to the problems relating to secondary courses in agriculture. The agencies for instruction of this grade are of several different kinds, as follows:

(1) High schools connected with agricultural colleges; (2) separate agricultural high schools endowed by the State; (3) agricultural schools for negroes in the Southern States; (4) private agricultural schools; (5) agricultural courses in normal schools; and (6) agricultural courses in public high schools.

1. The first agricultural high school to be established in connection with an agricultural college was the school of agriculture of the Uni-

versity of Minnesota, which has recently closed its fifteenth year of successful work. Its equipment and staff of instructors are in every way comparable with the best of our agricultural colleges, and its course of study, covering three years of six months each, includes: For the boys, music, English, mathematics, drawing, botany, chemistry, agricultural physics, agronomy, animal husbandry, dairying, horticulture, poultry culture, dressing and curing meats, forestry, veterinary science, carpentry, blacksmithing, and military drill; for the girls, the same subjects, except that courses in domestic science and practice are substituted for shop work and a portion of agriculture and gymnastics for military drill. For young men practical experience in field work at the university farm or elsewhere is required for graduation. The enrollment of the school is now nearly 500.

The school offers a practical course of study designed to fit young men and young women for successful farm life and it serves as a preparatory school for the college of agriculture. It is said that nearly all of its graduates not only return to the farm, but generally succeed. Many of the young men are growing up into leadership in their respective communities, and many more, by their quiet example, are bringing about a more hopeful view of the country and farming.

A school on essentially the same plan but without the courses in domestic science is maintained at the University of Nebraska. This school in 1902-3 had an enrollment of 207 boys.

2. Separate agricultural high schools, endowed by the State, are found in Wisconsin, Alabama, and California. In Wisconsin two such schools have been established in accordance with a State law of 1901 authorizing any county "to appropriate money for the organization, equipment, and maintenance of a school of agriculture and domestic economy," and providing that upon the approval of the State superintendent of public instruction the State will pay a share of "not to exceed one-half the amount actually expended for instruction in such school," in any county.

The Marathon County School of Agriculture and Domestic Economy, located at Wausau, Wis., was opened October 6, 1902. The buildings and equipment provided for this school cost \$20,000. The school grounds cover 6 acres. The course of study for boys includes soils, plants, animal husbandry, rural architecture, blacksmithing, carpentry, and mechanical drawing; for girls, cooking, laundering, sewing, floriculture, and home management and decoration. Both courses include English language, literature, United States history, civil government, and commercial arithmetic, with farm accounts. Tuition is free to residents of Marathon County, and the enrollment the first of last December was 62.

The other school is located at Menomonie and is known as the Dunn County School of Agriculture and Domestic Science. This school is equipped with a fine brick main building, erected by the county at a

cost of \$16,000 for the joint use of this school and the county teachers' training school, and a frame building for shop work which, with the grounds surrounding the school, cost \$5,000. The course of study covers two years and is very similar to that in the Marathon County school. Tuition is free to residents of Dunn County, and the enrollment in December last was 44.

In Alabama a State law passed in 1896 provided for the establishment of agricultural schools in each of the nine Congressional districts of the State, and appropriated to each of these schools \$2,500 a year, which is supplemented by local funds. As actually established, these schools have been a combination of elementary and high schools, in which a general education has been given with a limited amount of instruction in agriculture. Farms are connected with the schools in which, in some cases, simple field experiments have been conducted. Over 2,000 boys and girls annually attend these schools, and several hundred of them receive some instruction in agriculture.

In California a State appropriation has been made for a polytechnic school to be located at San Luis Obispo, in which agricultural education of secondary grade will be a leading feature. Plans are being made for the opening of this school at an early day.

3. Courses in agriculture of approximately high-school grade are maintained at a number of schools for negroes in the Southern States. The Hampton Normal and Agricultural Institute in Virginia has a well-organized course of this character. A considerable number of students in the institute have previously attended the elementary school known as the Whittier School, which is a public county school located on the grounds of the institute and furnished by it with teachers. It is a practice school for the normal students in the institute and includes a kindergarten and five grades. All the boys and girls in this school, from the kindergarten up, have nature study, elementary studies in plant life, soils, and insects, and work in a garden attached to the school.

At the institute the regular course, which is given in a day school, covers the studies ordinarily taught from the sixth to the ninth grades, inclusive, and occupies three years. Pupils who have no funds may attend the night school to prepare themselves for the day school, meanwhile earning money by farm work during the day. Instruction in agriculture is given in both the day and night schools, and includes instruction in soils, plant protection, animal industry, dairying, drainage, and farm management. A supplementary course is offered to those intending to prepare themselves to be agricultural teachers or farm superintendents. The institute has an excellent equipment of laboratories and apparatus, farm implements, live stock, orchards, and arable land.

Agricultural courses on substantially the same plan are conducted at the Tuskegee Normal and Industrial Institute in Alabama. Among the

other schools for negroes where successful agricultural courses are maintained are the Agricultural and Mechanical College for Negroes, Normal, Ala.; State College for Colored Students, Dover, Del.; Florida State Normal and Industrial College, Tallahassee, Fla.; Georgia State Industrial College, College, Ga.; State Normal School for Colored Persons, Frankfort, Ky.; Southern University and Agricultural and Mechanical College, New Orleans, La.; Alcorn Agricultural and Mechanical College, Westside, Miss.; Agricultural and Mechanical College for the Colored Race, Greensboro, N. C.; the Colored Normal, Industrial, and Mechanical College of South Carolina, Orangeburg; West Virginia Colored Institute, Institute, W. Va.

4. Within the past few years a number of private agricultural schools of secondary grade have been established. One of the most successful of these institutions is the National Farm School, at Doylestown, Pa. This school was established in 1896, and is supported by private donations, sales of farm products, and tuition fees. A State appropriation of \$2,500 a year for two years became available in 1901, and the State legislature has recently increased the appropriation for the next biennial period. The equipment consists of a farm of 122 acres, main building, barn, greenhouses, and live stock. The course of study covers four years, and includes the English, mathematics, and natural sciences usually taught in a high school, together with a considerable amount of instruction in the science and practice of agriculture. About forty boys, mostly from cities, attend the school and perform a large part of the labor necessary to carry on the farm. Eight boys graduated in 1901, six of whom are employed on farms, and two have been assistants in the Bureau of Soils of this Department.

A similar school of slightly lower grade is the Baron de Hirsch Agricultural School, established in 1891 at Woodbine, N. J., and a secondary school, known as the Winona Agricultural and Technical Institute, has recently been established at Winona Lake, Ind., with a graduate of Purdue University in charge of the agricultural department.

5. In order to prepare teachers to give instruction in agriculture in the public schools of the State, short courses in agriculture and horticulture have been given at summer schools held in connection with the University of Missouri. These courses were, however, necessarily too limited in extent to fully meet the requirements of such work, and courses in agriculture have therefore been established in the three State normal schools, located at Kirksville, Warrensburg, and Cape Girardeau. At the first the course in agriculture occupies nine and one-half months; at the second, five months; at the third, ten months. The demand for normal instruction in agriculture has led the agricultural colleges of Connecticut and North Carolina to plan this year summer schools for teachers, in which agricultural subjects will be prominent.

6. All of these agencies combined can not fully supply the need for

secondary instruction in agriculture. It is believed, therefore, that the public high schools in or near the rural communities should offer courses of instruction in agriculture. These schools draw heavily upon the adjacent rural communities for their students and should modify their courses accordingly. In order to point out the feasibility of introducing agricultural courses into the high school programmes, the committee on methods of teaching agriculture of the Association of American Agricultural Colleges and Experiment Stations, in its report to the convention of the association held at Atlanta, Ga., in October, 1902, outlined a number of high-school courses in which agricultural topics were included. These were intended to show that such courses may be offered in the high schools without any violent or radical reorganization of existing programmes for such schools, the agricultural subjects, as a rule, taking the place of Latin or Greek in the smaller schools and being offered as electives in the schools where the elective system prevails.

At present the problem of obtaining properly qualified teachers for this work is a serious one. Most of the teachers now employed in the public high schools have been trained in literary and scientific institutions or in technical schools where no agriculture has been taught. It is only now and then that a teacher is found who is in real sympathy with agricultural education. Text-books on agricultural subjects, suitable for secondary schools, are also extremely scarce; but the trained teachers will appear and suitable text-books will be provided when the demand for these grows strong enough. What is especially needed now is an organized propaganda through the agricultural colleges, agricultural societies, boards of agriculture, farmers' institutes, the agricultural press, and other agencies, with a view to impressing on school officers and teachers and on the agricultural masses the importance and desirability of giving serious and active attention to this matter. Every successful effort to maintain an agricultural high school or an agricultural course in a public high school will add momentum to this movement. When the advantages to be derived from agricultural high schools and secondary courses in agriculture in public high schools are once clearly demonstrated in a few places, it will not be difficult to persuade the taxpayers generally to contribute the necessary funds for their maintenance.

Technical education has proved a sure road to commercial development and greatly increased wealth in connection with every industry which has received its benefits. It will prove equally so as regards agriculture. The tremendously productive results which have already come from the work of the agricultural colleges and experiment stations may be multiplied a hundredfold by introducing into the secondary schools definite and systematic teaching of the technique and scientific principles of agriculture.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

Errors in manure sampling and analysis, W. FREAR (*Proc. Soc. Prom. Agr. Sci.* 1902, pp. 183-194).—The general plan of sampling employed “involved the careful weighing of the entire mass of each manure, its immediate mixture, and reduction by partings, with repeated mixing between successive partings, until approximately aliquot portions of 50 to 75 lbs. each were obtained. Triplicate aliquots being taken, they were each finally subdivided, again mixed and parted, about one-fifth to one-seventh of each triplicate being reserved for analysis. Loss of weight during handling was checked by frequent reweighings.

“The weighings were made in a tared, metal-lined cask, having a capacity of 75 to 100 lbs. This cask was frequently retared during the weighings to correct for slight gains by small amounts of adherent matter, from which it was, however, kept as free as possible by frequent cleaning. The average tare was judged to be correctly represented by the average of the frequent tare weighings made. The scales employed weighed to 7 gm.”

The analytical determinations, generally in triplicate, included: “(1) Nitrogen, by the König method: Two hundred grams manure dissolved to a paste in 650 to 1,150 gm. of concentrated sulphuric acid, 10 to 20 gm. of the paste taken for determination by the ordinary Kjeldahl method; (2) nitrogen in air-dry substance: Immediately after air drying, later, as a check upon change in hygroscopic moisture; (3) water-soluble nitrogen: One gram, washed on filter with 200 cc. of water, nitrogen determined in insoluble residue; . . . (4) ammoniacal nitrogen: One gram distilled with 250 cc. of water and 5 gm. of suspended magnesia under 22 to 25 in. vacuum for 30 to 45 minutes; . . . (5) hygroscopic moisture: Two grams in water-oven to constant weight; (6) ash: Residue from 5 ignited at low red heat; (7) potash: In 10 gm. after carbonizing with sulphuric acid, by Lindo-Gladding method; (8) water-soluble potash: In solution made from 10 gm., by boiling, Lindo-Gladding method; (9) phosphoric acid: Five grams fused with sodium carbonate and potassium nitrate, fusion analyzed by molybdate-magnesia mixture method; (10) *matiere noire*: Ten grams treated as usual with weak hydrochloric acid followed, after washing, with 4 per cent ammonia water; (11) potash and phosphoric acid, associated with *matiere noire*: In residues by Lindo-Gladding and fusion methods.”

The studies were made on 2 lots of manure. The losses of weight at the second weighing were found to be 3.08 and 3.36 per cent, respectively; at the third weighing 4.6 and 7.98 per cent. “The large percentages of loss occurring during the thorough mixing of the material declare strongly the need for expedition and care at every other point to protect the manure from heat, wind, and large surface exposure whereby volatilization might be increased; they further emphasize the need for reweighing, at every parting, of the entire mass parted.”

There were ranges of 1.25 and 4 per cent in the determinations of moisture in duplicate samples. The variations in the determinations of other constituents are shown in the following table:

Variations in triplicate determinations of various constituents in two samples of manure.

Constituents.	Sample I.			Sample II.		
	(a)	(b)	(c)	(a)	(b)	(c)
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Ash.....	11.39	11.19	11.43	14.47	16.11	16.27
Nitrogen.....	2.40	2.29	2.23	2.22	2.19	2.33
Potash.....	3.22	3.28	3.25	3.55	3.46	3.60
Phosphoric acid.....	1.33	1.29	1.29	1.36	1.41	1.95

"We may conclude from the foregoing facts that a large mass of manure can be satisfactorily represented only by original samples of relatively large amount; that the latter must be thoroughly subdivided under conditions unfavorable to heating, and, so far as can be, to evaporation; that check weighings be made at every parting, and that, when the material is sufficiently mixed, triplicate subsamples should be taken for separate determination of loss in air-drying, at least, in order to guard against errors introduced by large inequalities in the moistness of samples. Furthermore, it is clear that in handling large masses of manure greater accuracy of final result will be secured by rapid weighing in large quantities on scales of low sensitiveness than by weighing in small quantities on more sensitive scales, because of the rapid drying which the manure undergoes under the latter conditions."

The estimation of available phosphoric acid in manures, W. F. SUTHERST (*Analyst*, 28 (1903), No. 324, pp. 66-71).—Comparative determinations of the solubility of the phosphoric acid of basic slag, basic superphosphate, precipitated phosphate, and coprolite in 1 per cent citric acid and in solutions of potassium binoxalate, bitartrate and bimaleate of the same degree of acidity as the citric-acid solution are reported. The potassium-binoxalate and bitartrate solutions gave results on basic slag agreeing quite closely with those obtained with 1 per cent citric acid. The potassium-bimaleate solution gave much lower results than the other solvents used. With the other phosphatic materials tested the solvents gave very discordant results. From the results of repeated extractions of basic slag and coprolite with 1 per cent citric-acid solution the conclusion is drawn "that practically the whole of the phosphoric acid in any manure is available for plant food, but that in some it is assimilable in a shorter time than others. Whether the usual method of testing the available plant food and the results obtained by it give any definite idea of the amount a plant is capable of absorbing or not, it seems from the experiments carried out that there is certainly a relation between the amount dissolved and the amount which is in an easily assimilable form, since the large proportion of phosphoric acid dissolved out of the basic slag by one treatment with citric acid as distinguished from that removed from coprolite in proportion to the total present easily accounts for the more rapid effect of basic slag on a crop than that of a ground mineral phosphate." The question as to what extent the action of the weak acid solvents used in determining the availability of phosphoric acid imitates natural processes due to acid excretions from the roots of plants is discussed at some length by the author and others, and the arbitrary character of such methods of determining availability of phosphoric acid was pointed out.

On the solution of insoluble calcium phosphate by means of ammonium citrate solutions, K. ZULKOWSKI and F. CEDIVODA (*Chem. Ind.*, 26 (1903), pp. 1-9, 27-33; *abs. in Chem. Centbl.*, 1903, I, No. 8, pp. 477, 478).—Investigations are reported which lead to the conclusion that solution of calcium phosphate in ammonium cit-

rate solutions depends upon the formation of neutral and acid calcium-ammonium citrates, of which the latter only are stable. The results of a study of the behavior of mono-, di-, and tri-ammonium citrates toward di-, tri-, and tetra-calcium phosphates are reported in detail.

On the determination of citric-acid soluble phosphoric acid, W. NAUMANN (*Chem. Ztg.*, 27 (1903), No. 12, pp. 120, 121).—The method proposed is as follows: Add $\frac{1}{2}$ liter of 2 per cent citric acid to 5 gm. of slag and shake in a rotary apparatus for $\frac{1}{2}$ hour. To 100 cc. of the filtered extract thus obtained add 8 cc. of strong nitric acid and heat first over a small flame and then boil until the volume is reduced to about 25 cc. Cool, add 25 cc. of strong sulphuric acid and 5 cc. of nitric acid, and heat until white fumes begin to come off (about 10 minutes), cool in the bath, and make up to a volume of $\frac{1}{2}$ liter. To 125 cc. of the filtered solution thus obtained add 35 cc. of concentrated ammonia, 50 cc. of 24 per cent ammonium citrate, and 25 cc. of magnesia mixture, and shake for $\frac{1}{2}$ hour to precipitate phosphoric acid.

The preparation of ammonium nitrate molybdic solution for the determination of phosphoric acid, A. MERCIER (*Bul. Acad. Roy. Belg.*, 16 (1902), pp. 389-393; *abs. in Chem. Centbl.*, 1903, I, No. 6, p. 359).—Various methods of preparing molybdic solution were compared. That preferred by the author is as follows: Dissolve 100 gm. of molybdic acid in 144 cc. of 10 per cent ammonia (sp. gr. 0.9593), make the volume to 500 cc. with water, and pour into 1 liter of nitric acid of 1.2 sp. gr.

The rapid determination of potash in kainit, M. PASSON (*Ztschr. Angew. Chem.*, 15 (1902), No. 49, pp. 1263-1265).—The method proposed is briefly as follows: Dissolve 10 gm. of the salt in 200 cc. of water acidified with 5 cc. of hydrochloric acid, boil, and add barium chlorid in excess to precipitate the sulphuric acid. Cool, make up to 500 cc. with alcohol, cool again, make up again to the mark, and filter. To 25 cc. of the filtrate add platinum chlorid solution and 125 cc. of 96 per cent alcohol, and stir for 5 minutes. Filter through a Gooch filter, wash with 80 per cent alcohol, then with ether, dry for 2 hours at 100° C., and weigh. Dissolve the precipitate with hot water, wash, and dry as before, and weigh again. The difference gives the potassium platinochlorid corresponding to 0.5 gm. of substance.

The determination of potash in fertilizers by substituting milk of lime for ammonia and ammonium oxalate as the precipitant, C. L. HARE (*Jour. Amer. Chem. Soc.*, 25 (1903), No. 4, pp. 416-420).—Previously noted (*E. S. R.*, 14, p. 109).

Modifications of an apparatus for the determination of nitrates and nitrites, E. COMMANDUCCI (*Staz. Sper. Agr. Ital.*, 35 (1902), No. 9, pp. 747-752, fig. 1; *abs. in Chem. Centbl.*, 1903, I, No. 3, p. 194).

The volumetric determination of nitric acid, J. K. PHELPS (*Ztschr. Anorgan. Chem.*, 33 (1902), p. 357; *abs. in Chem. Ztg.*, 27 (1903), No. 15, *Repert.*, p. 35).—Tests of the accuracy of a modification of Holland's method ^a are reported. With proper precautions, which are described, the method is said to give accurate results.

A simple method for the quantitative determination of nitric acid in water, G. FRERICHS (*Arch. Pharm.*, 241 (1903), No. 1, pp. 47-53).—The method proposed rests upon the fact that the nitrates are readily converted into chlorids by the addition of hydrochloric acid and the excess of the acid may be removed by evaporation. Thus by determining chlorin in the original solution; adding hydrochloric acid, evaporating to dryness, and determining the chlorin in the residue; subtracting the results of the first determination from the second and multiplying the remainder by 1.525 the N_2O_5 present in the water may be obtained.

The determination of hardness in water, W. PETERS (*Apoth. Ztg.*, 18 (1903), pp. 25, 26; *abs. in Chem. Centbl.*, 1903, I, No. 7, p. 418).—For waters containing large amounts of magnesia in addition to lime the author uses Wartha's method.

^a *Chem. News*, 17 (1868), p. 219.

Analysis of milk and dairy products (*Nord. Mejeri Tidn.*, 18 (1903), No. 11, p. 142).—Official methods of analysis adopted by the Agricultural Department of Sweden for the State and County Chemical Control Station.—F. W. WOLL.

The determination of the percentage of water in butter (*Jour. Dept. Agr. and Tech. Instr. Ireland*, 3 (1902), No. 1, pp. 82-92).—This discusses different methods of sampling and analysis and gives the results of comparative tests. The most satisfactory method of sampling was the use of a large trier thrust vertically through the bulk of the butter, the core so obtained being placed in a glass-stoppered bottle, melted, shaken, and afterwards cooled. Of the ordinary analytical methods for determining moisture the use of a flat-bottomed porcelain dish and pumice stone is considered the most accurate, the details of manipulation as recommended for creamery and factory managers being given.

The application of Wollny's refractometer to the determination of the fat content of skim milk, C. BARTHEL (*Nord. Mejeri Tidn.*, 18 (1903), No. 6, p. 71).—Comparisons of determinations of the fat content of 134 samples of separator skim milk by the refractometer and Gottlieb's methods led to the conclusion that the former method is well adapted for use where a large number of determinations are to be made. The average difference of the determinations by the two methods was 0.01 per cent, a difference of 0.05 per cent occurring in 2 cases, 0.04 per cent in 5 cases, and 0.03 per cent in 17 cases. Thirty-eight comparative determinations were alike.—F. W. WOLL.

Methods of incineration for determining chlorin in animal solutions and organs as well as in foods, C. STRYZOWSKI (*Oesterr. Chem. Ztg.*, 6 (1903), pp. 25-28; *abs. in Chem. Centbl.*, 1903, I, No. 10, p. 661).—In the method proposed the substance is dried and carefully incinerated in presence of magnesium oxid (1 gm. to 20 cc. of solution or 10 gm. of the solid substance moistened with 10 to 15 cc. of water). The product thus obtained is dissolved in the exact amount of sulphuric acid required for complete solution and the chlorin is determined by titration according to the Mohr method.

The chemistry of plant and animal life, H. SNYDER (*Easton, Pa.: Chemical Pub. Co. Press*, 1903, pp. XVI + 406, figs. 102).—This volume, which is designed as a text-book suitable for the instruction in chemistry of students in agricultural colleges, contains chapters on the foundation principles of chemistry, the chemistry of plant growth, the composition of plants, feeding value of different crops, rational feeding of animals, and related topics. In every case the explanations are full and clear, and the volume should prove a useful handbook, especially since the subjects presented and the methods of treatment are such that the relations of chemistry to everyday life are emphasized.

Text-book of agricultural chemistry, A. MAYER (*Lehrbuch der Agrikulturchemie*. Heidelberg: Carl Winter, 1902, 5. rev. ed., vol. 2, pt. 2, pp. VI+253, figs. 3).—This is the second and concluding part of the second volume of the fifth revised edition of this work (E. S. R., 13, p. 913). The first part of this second volume deals with soils; the second part is devoted to fertilizers. The third and last volume of this work, which is now in course of preparation, deals with the chemistry of fermentation.

The application of the equilibrium law to the separation of crystals from complex solutions and to the formation of oceanic salt deposits, E. F. ARMSTRONG (*Rpt. British Assoc. Adv. Sci. 1901*, pp. 262-282, figs. 5).—This is a paper compiled from a series of 23 papers by van't Hoff and his pupils (E. S. R., 14, p. 430), published since the year 1897 in the proceedings of the Berlin Academy of Sciences. The author states that "apart from these and the information given by van't Hoff in his text-books, there are only two other papers bearing on the subject—one by van der Heide,^a the other by Löwenherz."^b

^a*Ztschr. Physikal. Chem.*, 12 (1893), p. 416.

^b*Ztschr. Physikal. Chem.*, 13 (1894), p. 459.

Methods for the investigation of canceling inks and other stamping inks, E. E. EWELL (*U. S. Dept. Agr., Bureau of Chemistry Circ. 12, pp. 8*).

New laboratory apparatus, C. ZAHN (*Chem. Ztg., 27 (1903), No. 7, pp. 69, 70, figs. 3*).—Descriptions are given of burettes with automatic arrangements for filling to the zero point, and of a pipette for use in Gerber's milk test.

Report of the Swedish chemical control stations for 1900, A. LYTTEKENS (*Ber. K. Lantbr. Sty., 1900, pp. 335-357*).—The 10 chemical control stations supported by the Swedish Government examined 54,691 samples of agricultural products during the year, of which number over 46,000 were dairy products. The 8 chemical stations supported by county agricultural societies examined 3,687 samples, of which number nearly two-thirds were dairy products. Summaries of the results of analyses of soils, fertilizers, feeding stuffs, dairy products, etc., for all stations are presented in the report.—F. W. WOLL.

BOTANY.

North American species of *Leptochloa*, A. S. HITCHCOCK (*U. S. Dept. Agr., Bureau of Plant Industry Bul. 33, pp. 24, pls. 6, figs. 16*).—In order to clear up some of the bibliographical and taxonomic difficulties in this genus the author has reviewed the North American species, giving a key and diagnostic description to those species occurring within the range indicated. With one or two exceptions most of these species are confined to the warmer parts of the country and one species (*Leptochloa dubia*) is an important range grass in the Southwest.

Notes on the poisonous plants of Nebraska, C. E. BESSEY (*Proc. Soc. Prom. Agr. Sci. 1902, pp. 34-41*).—A general summary is given of a more extensive paper in which 12 species of plants reputed poisonous to man externally, 29 internally, and 35 species poisonous to stock are described. In the summary only those are enumerated and described which are rather definitely known to be injurious.

Notes on fungi, C. G. LLOYD (*Mycological Notes, 1903, No. 13, pp. 121-132, pls. 4, figs. 2*).—Keys are given, together with technical descriptions of the species of *Catantoma* and *Mitremyces*. Miscellaneous notes are also given of *Geaster fornicatus*, *Dictybole texensis*, *Torrendia pulchella*, etc.

Note on the water content of certain plants, W. R. LAZENBY (*Proc. Soc. Prom. Agr. Sci. 1902, pp. 195-200*).—A report is given of a series of observations made upon the water content of a number of plants on account of the bearing of this factor on the effect of drought and frost on the plants. The accompanying table shows the percentage of water in the foliage and twigs of a number of varieties of fruits:

Percentage of water in foliage and twigs.

Variety.	Foliage.		Twigs.	
	Septem-ber 21.	October 7.	March 23.	April 2.
	Per cent.	Per cent.	Per cent.	Per cent.
Delaware grape.....	57.80	48.35	39.89
Concord grape.....	53.78	49.84	42.00
Osthelm cherry.....	50.04	41.63	47.15	49.66
Ida cherry.....	51.40	48.64	53.11	51.59
Snyder blackberry.....	45.50	45.71	46.86	49.01
Wilson, Jr., blackberry.....	42.51	41.17	49.57	46.66
Duchesse pear.....	45.78	44.47	49.55	51.82
Keiffer pear.....	48.60	45.70	51.44	51.35

The percentage of moisture in a number of forest trees was also determined at different periods, the average percentage being shown in the accompanying table:

Average percentage of moisture in forest trees.

Kind.	Decem- ber 1, 1898.	March 2, 1899.	April 15, 1899.	May 24, 1899.	Average.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Poplar.....	52.3	52.6	54.6	56.4	53.9
Maple.....	56.5	45.4	43.4	52.3	49.4
Walnut.....	52.7	41.9	45.5	56.5	49.1
Cucumber.....	42.4	57.8	49.4	60.1	52.4
Ash.....	37.2	45.6	40.1	55.1	44.5
Oak.....	41.8	41.2	40.2	53.6	44.2
Elm.....	43.9	41.7	51.9	56.3	48.4
Total average	46.6	46.4	46.4	55.7	48.8

The influence of humidity on the formation and development of stomata, G. MARIANA (*Separate from Atti Inst. Bot. Univ. Pavia, 2. ser., 8 (1902), pp. 32*).—Studies are reported on the effect of humidity on the development of stomata on the cotyledonary leaves of a number of plants such as buckwheat, beets, radishes, balsam, white lupine, crimson clover, plane tree (*Acer pseudoplatanus*), gourds, etc. According to the author, humidity favors the development of the superficial area of the cotyledons, and for a given area there are usually fewer stomata per unit of surface of those cotyledons produced in moist atmospheres. The development of the epidermal cells in the cotyledonary leaves follows the same rule. In general a humid atmosphere favors the formation of stomata, although not increasing their number. Humidity and drought were found to have no effect in influencing the relative number of stomata on the two surfaces of the leaves.

The effect of concentration of solutions on the respiration of plants, W. PALLADINE and A. KOMLEFF (*Rev. Gén. Bot., 14 (1902), No. 168, pp. 497-516*).—The effect of different concentrations of saccharose on the respiration of a number of different plants is reported. The results obtained show, so far as the respiratory energy of the plants was concerned, that the respiration of the plant was highest when solutions of average concentration were used. If stronger or weaker solutions were employed there was a marked falling off in the respiration of the plants. The effect of sudden changes in the strength of solution showed that changing etiolated leaves of beans from a strong to a weak solution resulted in a rapidly increased respiration, while transferring them from a weak to a stronger one diminished the respiratory energy.

The influence of mineral salts on the respiration of plants during germination, S. KRZESNIENIEWSKI (*Separate from Bul. Acad. Sci. Cracovie, 1902, pp. 1-41, pls. 2; abs. in Bot. Centbl., 90 (1902), No. 19, pp. 525, 526*).—After reviewing the investigations of others relating to the action of certain minerals on germination the author gives a report of his investigations on the influence of the various mineral salts contained in the Knopp solution on the germination of radish seed. It was found that the respiration of plants began at the time the seed began to swell and increased quite rapidly as soon as the radicle began to appear. The proportion of carbon dioxide to oxygen was equal to 1 at the beginning of the experiment but it rapidly diminished as the respiration reached its maximum. The different salts which entered into the composition of the Knopp solution did not affect the respiration in the same manner. The potash salts were most active and where these were omitted the respiration was very low. Practically the same results were obtained with the nitrates.

The effect of temperature on carbon dioxide assimilation, G. L. C. MATTHÆI (*Ann. Bot., 16 (1902), No. 64, pp. 591, 592*).—An abstract is given of a paper presented before the British Association for the Advancement of Science, which shows the effect of temperature on the assimilation of various leaves. A number of leaves

of the cherry laurel were kept for some time under exactly similar conditions, and the effect of temperature noted. The lowest temperature at which assimilation could be detected was -6°C ., and this is said to be the first well-established case of assimilation taking place at a temperature below 0°C . For temperatures between -6°C . and 33°C ., it was found that assimilation is affected in the same way as is respiration. If the illumination is sufficient the assimilation increases directly with the temperature. For temperatures above 33°C . the results are complicated by the injurious effects of temperature, and the death of the leaves took place at 41 to 45° as was shown by a rapid decrease in the respiration which ceases entirely after several hours.

Influence of previous environment in variety tests, T. L. LYON (*Proc. Soc. Prom. Agr. Sci.* 1902, pp. 70-73).—An account is given of a series of experiments with Turkish red wheat which was obtained from Ohio, Iowa, Kansas, and Nebraska and grown at the Nebraska Station. Although this variety is supposed to be a fairly constant one, wide differences are noted in the yield of grain and character of the plant grown from the different lots. The author believes that the habits of growth of the wheat plant are very readily changed by its environment and that a few years are sufficient to produce a great difference in this respect. While certain variety characteristics undergo slight changes others are deeply affected and reliable conclusions can not be based upon variety experiments in which the material is collected from regions differing widely in their climatic conditions.

The individuality of plants as a factor in nutrition studies, E. B. VOORHEES and J. G. LIPMANS (*Proc. Soc. Prom. Agr. Sci.* 1902, pp. 42-49).—Attention is called to the importance of considering the individuality of the plant as a factor in plant studies, especially when but a few individuals are under observation. Examples are cited of pot experiments with several varieties of plants in which wide variations were noted in the growth and yield of the different plants. The conditions of the experiments were practically identical and the variation could be attributed only to the individuality of the plants. The aim of the paper was to emphasize the particular influence of plant individuality in plant nutrition studies so as to awaken suggestions as to the best means for reducing such influences to a minimum.

On the decomposition of proteid materials in plants, H. KARAPÉTOFF and M. SABACHNIKOFF (*Rev. Gén. Bot.*, 14 (1902), No. 167, pp. 483-486).—It having been shown by several authors that the quantity of nondigestible proteid material in plants depends upon the respiratory energy, the authors conducted a series of experiments to investigate the effect of depriving plants of all sources of food to ascertain the effect on the transformation of nondigestible proteids. Young seedlings of wheat and barley were separated into equal lots, one of which was immediately analyzed and the other was kept in the dark for a considerable time, after which the plants were analyzed by the same method as used for the analysis of the fresh ones. The results of the experiments show that in the absence of nutrition the nondigestible proteid material in plants had decomposed very slowly. For a few days there was an increase, after which a gradual diminution of the total proteids of the plants.

The influence of wounds on the formation of proteid material in plants, J. KOVCHOFF (*Rev. Gén. Bot.*, 14 (1902), No. 167, pp. 449-462).—Studies are reported on the effect of cutting bulbs on the production of nondigestible proteids in plants. Several varieties of onions were experimented upon, the bulbs being cut in half, one portion placed in a dark humid atmosphere and the other analyzed at once. The author found that wounding resulted in an increase in the nondigestible proteids. This increased in a greater proportion than the total proteids. In the absence of oxygen the nondigestible proteids made little or no increase when subjected to the other conditions of the experiment.

Investigations on vegetable oils and their formation, especially in the olive, C. HARTWICH and W. UHLMANN (*Arch. Pharm.*, 240 (1902), No. 6, pp. 471-480).—The authors describe the microchemical reaction of various vegetable oils, after which particular attention is given to the formation of oil in the fruit of the

olive. The olive fruits were subjected to analyses from time to time during the growing season and the results of the analyses are given. The authors have divided the growing season into 3 periods: The first, in which there is but a very slight amount of oil present in the fruit; the second, which occurs from August to October, is a period of rapid oil formation; and the third, which occurs from October to February, is the period of ripening and the time at which the olives are mostly gathered. The oil content of the fruit increases up to January, after which there seems to be a decided decrease through that and succeeding months. The highest oil content of the fruits examined was 30.1 per cent for the flesh of the fruit, the analysis being made on January 16.

Pot experiments to determine the limits of endurance of different farm crops for certain injurious substances, F. B. GUTHRIE and R. HELMS (*Agr. Gaz. New South Wales*, 14 (1903), No. 2, pp. 114-120).—An account is here given of experiments with wheat plants grown in galvanized iron pots 8 in. high and 8 in. in diameter to test the effects on the growth of the plants of the following substances: Common salt (0.01 to 1 per cent), sodium carbonate (0.01 to 3 per cent), ammonium sulphocyanid (0.001 to 0.5 per cent), sodium chlorate (0.001 to 0.5 per cent), and arsenious acid (0.01 to 1 per cent). The results are summarized in the following table:

Effects upon germination and subsequent growth of the wheat plant of different percentages of injurious substances in the soil.

	Germination affected.	Germination prevented.	Growth affected.	Growth prevented.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Common salt.....	0.050	0.20	0.05 to 0.15 (recov.)	0.200
Sodium carbonate.....	.300	0.5 to 1	0.100	.400
Ammonium sulphocyanid.....	.005	.01	.001	.005
Sodium chlorate.....	Above .100	.05	.001	.003
Arsenious acid.....	.050	Above .50	.050	.100

Some modifications produced by freezing on the structure of plant cells, L. MATRUCHOT and M. MOLLIARD (*Rev. Gén. Bot.*, 14 (1902), Nos. 167, pp. 463-482; 168, pp. 522-533, pls. 3).—Cytological studies are reported showing the effect of freezing upon many different plants. The phenomena described show a marked parallelism between the phenomena observed in desiccation and freezing, and the authors concur with Molisch that the death of the cell or plant by freezing is in reality due to the rapid drying out of the tissues.

The rate of absorption of nitrogen by cereals, J. HENRY (*Bul. Agr. [Brussels]*, 19 (1903), No. 1, pp. 154-156).—A study was reported in which the author sought to learn the relative rate of nitrogen absorption from the soil in the case of barley, wheat, and rye grown in pots fertilized with nitrate of soda and sulphate of ammonia. The pots containing the plants were prepared in a similar manner, seeded, and specimens removed at stated intervals for analysis, the nitrogen being determined by the Kjeldahl-Jodbauer method. The results show that the period of absorption varies quite widely. For some time the absorption may be very slow and insignificant, while at other periods it is two or three times as active for the same length of time. During the most active periods of growth the nitrogenous fertilizers seem to be used most abundantly. For wheat the 2 periods of maximum absorption were between May 7 and 17, and the second at the time of the formation of the grain. With rye the maximum absorption took place between April 19 and 29 and between June 11 and 26, corresponding to the same periods of plant development as for the wheat. The maximum absorption of nitrogen for barley took place between June 12 and 26 at the time when the heads were appearing.

Recent investigations on the root tubercles of Leguminosæ, L. HILTNER and K. STÖRMER (*Arb. K. Gesundheitsamte, Biol. Abt.*, 3 (1903), No. 3, pp. 151-307,

pls. 4, figs. 5).—A brief review is given of the field trials with Nitragin prior to 1900, and the tests for that and the succeeding year are reported upon at considerable length. Of the tests conducted in various parts of the country during 1901 it is claimed that 54 per cent of all reported gave very favorable results. The experiments conducted at the Dahlem Station under the authors' direction gave almost uniformly increased growth when inoculated with pure cultures. Experiments were made in which the relative efficiency of treating the seed and the soil with solutions containing pure cultures was compared. A number of laboratory experiments are reported showing the effect of various factors on the development of root tubercles. Among the factors studied were the influence of the materials found in the endosperm of the seed; effect of grape sugar; various nitrogenous substances, such as salt-peter, asparagin, peptone, and combinations of these substances with grape sugar; the effect of phosphoric acid used alone and in combination with other substances; and effect of organic acids, etc., upon the root-tubercle organism. The value of pure cultures of the physiologically specialized organisms is also reported upon at considerable length. The paper concludes with some brief references to the investigations conducted during 1902 by the authors on the perfection of methods of inoculation.

Observations on some algæ causing "water bloom," N. P. B. NELSON (*Minnesota Bot. Studies*, 3. ser., 1903, pt. 1, pp. 51-56, pl. 1).—On account of the sanitary importance of some algæ in the sources of water supply the author has made a study of the species which produce the condition known as "water bloom" in a number of localities in Minnesota. So far as known there is no record of the occurrence of any of these injurious algæ to any great extent in the rivers or lakes supplying drinking water to the cities and towns of the State, but in several instances the death of cattle and other animals has been attributed to the presence of these organisms. As a result of the author's investigations 7 species of blue-green algæ which form water bloom are known to occur in the State, the species being as follows: *Gleotrichia pisum*, *Celosphaerium kuetzingianum*, *Aphanizomenon flos-aquæ*, *Clathrocystis aeruginosa*, *Anabaena circinalis*, *A. flos-aquæ*, and *A. mendotæ* (?). In several instances it has been almost conclusively proved that the presence of one or more of these species in drinking water used by stock has caused fatal results.

The suspension of life at low temperatures, A. MACFADYEN and S. ROWLAND (*Ann. Bot.*, 16 (1902), No. 64, pp. 589, 590).—An abstract is given of a paper presented by the authors before the British Association for the Advancement of Science, showing the results of experiments with various bacteria and other organisms, when subjected to the temperature of liquid air and liquid hydrogen. Altogether 10 organisms were cooled to a temperature of -190° C. for 7 days without producing any appreciable depreciation of their vitality either as to their growth or their other physiological or pathogenic properties. Later the organisms were subjected to temperatures of -252° C. by means of liquid hydrogen. In this case a number of different pathogenic and other organisms were subjected to this temperature for a period of 6 months and in no case was any reduction in the vitality of the organisms detected. After this period of subjection to low temperatures yeasts gave good growth and exhibited unaltered powers of fermentation. Typhoid bacillus retained its pathogenic and other properties while the other bacteria responded to the various tests applied to them. It appears that the ordinary manifestations of life cease at zero, but at -190° C. it is believed that even intracellular metabolism ceases as a result of the withdrawal of all heat and moisture from the organism.

The necessary presence of bacteria in cultures of Myxomycetes, PINOY (*Bul. Soc. Mycol. France*, 18 (1902), No. 3, pp. 288, 289; abs. in *Bot. Centbl.*, 90 (1902), No. 11, p. 303).—The author claims that it is nearly, if not quite, impossible to secure cultures of many Myxomycetes in pure media, but when the cultures are mixed in the presence of *Bacillus luteus* he has been able to successfully grow various stages of *Didymium effusum* and other forms.

METEOROLOGY—CLIMATOLOGY.

Report of the Chief of the Weather Bureau, 1901-2 (*U. S. Dept. Agr., Weather Bureau Rpt. 1901-2, pp. 342, charts 5*).—The first part of this report contains an account of the operations of the Weather Bureau during the year; part 2, a list of observing stations and changes therein during 1901, and hourly averages of atmospheric pressure, temperature, and wind from the records of automatic instruments at 28 stations; part 3, monthly and annual meteorological summaries for 171 Weather Bureau stations; part 4, monthly and annual means and extremes of temperature and dates of first and last killing frosts, 1901; part 5, monthly and annual precipitation, 1901; and part 6, miscellaneous meteorological tables and reports.

Annual summary of meteorological observations in the United States, 1902 (*Mo. Weather Rev., 30 (1902), No. 13, pp. VII+603-633, pls. 22, charts 7*).—This number gives a table of contents, list of corrections, additions, and changes, and an index for volume 30; and a summary of observations on temperature, pressure, precipitation, wind movement, cloudiness, and other meteorological phenomena "based essentially upon data received from about 166 regular Weather Bureau stations, 33 regular Canadian stations, and voluntary stations from such States as have forwarded their annual summaries in time." The following special articles are included: The Red River Flood of November and December, 1902, by J. W. Cronk; Cannon and Hail, by J. R. Plumandon; and Studies among the Snow Crystals during the Winter of 1901-2, with Additional Data Collected during Previous Winters (illus.), by W. A. Bentley.

Meteorological chart of the Great Lakes, A. J. HENRY and N. B. CONGER (*U. S. Dept. Agr., Weather Bureau, Meteorological Chart of the Great Lakes, 1902, No. 2, pp. 17, charts 4*).—This is the usual summary of observations for the season of 1902 on storms, atmospheric precipitation, and lake levels, opening and closing of navigation, wrecks and casualties, fog, etc.

Meteorological observations, C. S. PHELPS (*Connecticut Storrs Sta. Rpt. 1901, pp. 246-250*).—This is a record of observations on temperature, pressure, humidity, precipitation, and cloudiness during each month of 1901 at Storrs, and on rainfall during the 6 months ended October 31, 1901, at 22 places in Connecticut. The mean pressure for the year at Storrs was 29.98 in.; total precipitation 66.5 in.; number of cloudy days, 134. The average rainfall for the State during the 6 months ended October 31 was 27.80 in.

"The total precipitation for the year as recorded at Storrs . . . is the heaviest annual precipitation since the station began observations in 1888, being about 19.5 in. above the average (47 in.) for 13 years. The rainfall was exceptionally heavy during January, March, April, and May and again in July and December. . . . From the table of rainfall observations reported from 22 localities in the State, for the 6 months (May 1 to October 31), it will be noticed that the average rainfall for the State was quite heavy for each month except June. . . . The last killing frost occurred May 6, although the damage was not very general. . . . Frost held off well in the fall, the first to do much damage occurring September 26, thus giving a growing season of 142 days."

Meteorological observations, J. E. OSTRANDER and S. C. BACON (*Massachusetts Sta. Met. Buls. 169, 170, 171, pp. 4 each*).—Summaries of observations on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during January, February, and March, 1903. The data are briefly discussed in general notes on the weather of each month.

Meteorological record for 1901 (*New York State Sta. Rpt. 1901, pp. 410-419*).—Tables are given which show the average monthly temperature and precipitation since 1882; the daily wind record for each month of 1901; a monthly summary of the direction of the wind for the year; tridaily readings of the standard air ther-

monometer during each month of the year; a monthly summary of maximum, minimum, and standard thermometer readings; and daily readings of maximum and minimum thermometers at 5 and 6 p. m. for each month of the year.

Meteorological observations, D. V. C. MANZO DE ZUÑIGA (*Mem. An. Estac. Enol. Haro*, 1902, pp. 51, 52).—A summary is given of observations at this station during the year ended June 30, 1902, on atmospheric pressure, temperature, precipitation, humidity, evaporation, sunshine, cloudiness, and wind movement.

Meteorological tables, C. E. MAGNUSSON (*Bul. Hadley Climat. Lab. Univ. New Mexico*, 3 (1903), No. 5, pp. 14).—Summaries, by months, of observations at the University of New Mexico on temperature, precipitation, cloudiness, and wind movement during 10 years (1893-1902).

The availability of New Mexico's climate for outdoor life, J. WEINZIRL (*Bul. Hadley Climat. Lab. Univ. New Mexico*, 3 (1903), No. 6, pp. 9).

The climate of Garrett County, Maryland, O. L. FASSIG (*Maryland Geological Survey: Garrett County*. Baltimore: Johns Hopkins Press, 1902, pp. 252-273, figs. 7).—A summary is given of all available records of temperature, frequency of frosts, cold waves, the hot days, rainfall and snowfall, cloudiness, thunderstorms, and wind direction. A list of meteorological stations in the county, giving location, organization, equipment, etc., is added. The data reported show that "in general the climatic conditions for maturing crops are perhaps less favorable here than in any other section of Maryland. Greater extremes of cold are experienced in the winter, while the growing season is much shorter. This is due principally to the considerable elevation of the county as compared with the other counties. Usually spring does not begin until the middle of April, although it begins in the early part of March in the southeastern part of the State. The highest recorded temperature is 99°, while the lowest is -26°, recorded at Sunnyside. These figures give an extreme range of temperature of 125°, probably the greatest range in the entire State. The mean daily range of temperature is about 20°, or slightly more than that of the State. The normal annual temperature of the county is 47°, while that of the State is between 53 and 54°. Frosts are possible in almost any month of the year, but during a period of 3 years ending 1898 the last frost in the spring occurred May 30, and the first frost in the fall, September 12. The normal annual precipitation for Garrett County is 53.3 in., of which about 28 in. fall during the spring and summer months. The annual precipitation is about 10 in. greater than the recorded rainfall of the rest of the State."

The climate of Cecil County, Maryland, O. L. FASSIG (*Maryland Geological Survey: Cecil County*. Baltimore: Johns Hopkins Press, 1902, pp. 249-261, figs. 3).—A summary is given of all available data relating to temperature, rainfall, and snowfall.

A study of the climate of Tunis, G. GINESTOUS (*Bul. Dir. Agr. et Com. [Tunis]*, 8 (1903), No. 26, pp. 103-139, figs. 11, charts 9).—Previous articles (E. S. R., 14, p. 553) have summarized the meteorological conditions of Tunis by seasons. This article gives a detailed summary for the entire year.

Rainfall in the agricultural districts, C. L. WRAGGE (*Queensland Agr. Jour.*, 12 (1903), No. 2, p. 144).—A table gives the rainfall of December, 1901, and of each month of 1902 at 41 stations in Queensland.

Analysis of the rainfall records of New South Wales generally, and also of those of other states, J. BARLING (*Agr. Gaz. New South Wales*, 13 (1902), Nos. 8, pp. 877-879, pls. 5; 12, pp. 1188, 1189, pls. 2).—The analysis tends to show regularity or periodicity in rainfall variations for New South Wales, and that this region is now entering upon a favorable period as regards rainfall.

Investigation of the upper atmosphere by means of kites (*Jour. Soc. Arts*, 50 (1902), No. 2602, pp. 838, 859).—This is a report of the committee appointed by the Royal Meteorological Society to investigate this subject, and describes the apparatus installed and now in operation on the island of Crinan on the west coast of Scotland.

The use of barometric variations in forecasting weather, J. GUZMAN (*Mem. y Rev. Soc. Cient. "Antonio Alzate,"* 17 (1902), No. 6, pp. 215-230).—An argument

based on actual observation to show that barometric variations are of great value in forecasting, since it is claimed that by their means the centers of high or low pressure may be predicted from 12 to 24 hours in advance; they aid in fixing the trajectories of cyclonic and anti-cyclonic centers; and they are of use in forecasting temperature changes and in predicting the north and south winds of northern Mexico and the Gulf region.

WATER—SOILS.

Water supply and sewerage (*Massachusetts State Bd. Health Rpt. 1901*, pp. 1-393).—This includes advice to cities and towns on water supply, sewage disposal, etc.; the results of chemical (and in some cases microscopical) examination of water supplies and rivers; and accounts of experiments on sewage purification and bacteriological studies at the Lawrence Experiment Station.

Purification of river water, A. J. J. VANDEVELDE and F. LEPPERRE (*Reprint from Handel. Zesde Vlaamsch Natuur- en Geneesk. Cong., Kortrijk, 1902*, pp. 11, figs. 2).

The hydrography of Garrett County, Maryland, H. A. PRESSEY and E. G. PAUL (*Maryland Geological Survey: Garrett County. Baltimore: Johns Hopkins Press, 1902*, pp. 275-289, pl. 1, figs. 3).—A summary of available data on this subject.

The hydrography of Cecil County, Maryland, H. A. PRESSEY (*Maryland Geological Survey: Cecil County. Baltimore: Johns Hopkins Press, 1902*, pp. 263-287, pl. 1, figs. 8).—A summary of available data on this subject is given in tables and diagrams.

On the processes of mineralization of water as related to the geological character of soils and rocks, E. CASORIA (*Ann. R. Scuola Superiore Agr. Portici, 2. ser., 4 (1903)*, pp. 197).

Observations on soil moisture in New Mexico from the hygienic view point, C. E. MAGNUSSON (*Bul. Hadley Climat. Lab. Univ. New Mexico, 3 (1902)*, No. 4, pp. 8).—Observations with Whitney's electrical apparatus and by means of direct determination (drying) are recorded for a period of about one year and the results are discussed with reference to health.

An experiment on soil improvement, C. S. PHELPS (*Connecticut Storrs Sta. Rpt. 1901*, pp. 148-153).—A brief account is given of a continuation of a rotation experiment begun in 1899 (E. S. R., 13, p. 935). "The experiment on soil improvement in 1900 was with potatoes and that of 1901 with oat and pea hay. In both years the yield was largest on the plat with the complete fertilizer, but in proportion to the cost of fertilizing the two plats the yield on the plat with the stable manure was fully as economically produced. In 1900 the yield from the plat with clover for manure was next in size to that from the plat with the complete fertilizer, and the yield from the plat with the minerals and clover for fertilizer was practically the same as that from the stable manure. In 1901 the yields of oat and pea hay where a light growth of vetch was plowed under, either alone or in combination with the mineral fertilizers, were much smaller than those where stable manure was used. In both years the yield on the plat where rye was plowed under in addition to the minerals was less than those from the plats on either side where the legumes were used. The results of both years indicate a considerable advantage in the use of legumes for green manure. On the whole, common red clover seems to be the best crop for the purpose of green manuring when it must be grown between the regular crops of a rotation, as in the experiment here described."

Experiments on black marsh soils, A. R. WHITSON (*Wisconsin Sta. Rpt. 1902*, pp. 210-216, figs. 2).—In continuation of previous investigations (E. S. R., 13, p. 931), experiments were made on black marsh soils in 1901 (1) in cylinders which showed that green manure was nearly as effective as potash for corn on such soils; (2) in cylinders and in the field which showed that "the effect of potassium sulphate is limited to the first crop, while manure may influence the second crop largely and the third somewhat. With the ordinary distance of planting of corn, 50 to 75

lbs. [of potassium sulphate] per acre would appear to be the most profitable amount to use. In order not to prevent germination, this must be placed from 1 to 2 in. below or at one side of the seed in the hill."

The soils of Garrett County, Maryland, C. W. DORSEY (*Maryland Geological Survey: Garrett County. Baltimore: Johns Hopkins Press, 1902, pp. 233-252, pls. 2*).—An account is here given of a soil survey of this county, which lies in the extreme western portion of Maryland and has an area of 680 square miles. It consists mainly of a rolling plateau 2,000 to 2,500 ft. above sea level, broken by mountain ranges 2,500 to 3,400 ft. high. The article contains a general discussion of the origin and fertility of soils and of the relation of the agriculture to the physiography and climate of Garrett County, agricultural conditions, the history of soil investigations in the county, and soil formations. "There are comparatively few types of soil in Garrett County. They consist mostly of sandy loams and loams in the valleys and more gently rolling areas. In the mountainous districts there are always present large amounts of boulders, which make cultivation difficult. The soils are mainly residual, derived from the weathering of the shales, sandstones, and limestones." The type soils which are described, and of which mechanical analyses are given, are 10 in number, as follows: Jennings, Hampshire, Pocono, Greenbrier-Mauch Chunk, Pottsville, Allegheny, Conemaugh, Monongahela, Dunkard, and Quaternary.

The soils of Cecil County, Maryland, C. W. DORSEY and J. A. BONSTEEL (*Maryland Geological Survey: Cecil County. Baltimore: Johns Hopkins Press, 1902, pp. 227-248, pls. 3*).—This is an account of a soil survey which has already been noted from another source (E. S. R., 13, p. 925).

Preliminary crop and soil data for the cooperative study of available plant food, C. C. MOORE (*U. S. Dept. Agr., Bureau of Chemistry Circ. 11, pp. 9*).—This circular gives a description of the soils on which a chemical study (E. S. R., 13, p. 1014) has been made in different States by the experiment stations cooperating with the Bureau of Chemistry of this Department, and analytical data for the yield and fertilizing constituents of the crops grown.

Report on analyses of the soil of coffee plantations, J. G. KRAMERS (*Meded. 's Lands Plantentuin, 1902, No. 57, pp. 25*).—The author discusses the subject under the following heads: (1) The origin and nature of coffee soils in Java; (2) the relation between the soil and the plants; (3) the chemical analysis of the soil; and (4) the samples and the methods of investigation. Following the text is a long table, in which is given detailed analyses of all the soil samples, together with the reagents used in making the tests. The soils on which Java coffee is planted belong to the volcanic formation of the Tertiary and Quaternary periods, and consist of volcanic andesite and basalt or their decomposition products. Most of the cultivated soils of Java are underlaid by a hardpan which often prevents free drainage and ruins the soil for coffee culture.

The author also treats of the various mineral substances in the soil and the geological history of the mountains, and discusses the general principles of plant physiology as applied to the relation between the plant and the soil.—H. M. PIETERS.

The occurrence of climatic soil zones in Spain, RAMANN (*Ztschr. Ges. Erdk., 1902, pp. 165-168; abs. in Geol. Centbl., 3 (1903), No. 4, p. 136*).—On the basis of observations made during 1901 the author maps and discusses the distribution of soils in the Spanish Peninsula. Soils having the widest distribution are the steppes and half steppes, some of which are alkaline. A special type of the steppe soils is the Andalusian black soil, which differs in structure from the east European soils. The steppes are surrounded by a band of red siliceous soils containing considerable amounts of colloidal iron oxid. On the northwest coast, where the rainfall is abundant, humus soils are found.

The bacteriological analysis of soils, F. D. CHESTER (*Proc. Soc. Prom. Agr. Sci. 1902, pp. 173-182*).—This article is based on investigations already noted (E. S. R., 14, p. 232).

FERTILIZERS.

Culture trials with precipitated calcium phosphate, II, H. G. SÖDERBAUM (*Medd. K. Landtb. Akad. Exptlfält. [Stockholm], 1902, No. 75, pp. 14*).—The trials here reported are continuations of those conducted during the summer of 1900 (*E. S. R.*, 13, p. 836). The general plan of the trials was to ascertain the fertilizer value of tricalcium orthophosphate prepared from apatite through electrolysis, as compared with other phosphatic materials. The new series of trials were conducted during 1901 with 5 different phosphatic fertilizers, viz.: (1) Tricalcium phosphate prepared from "apatite concentrate," with sodium chlorate as electrolyte, and dried at 80° C. It contained 47.09 per cent lime, 0.76 per cent potash, and 34.30 per cent phosphoric acid, 28.38 per cent of phosphoric acid soluble in 2 per cent citric-acid solution, and 5.60 per cent soluble in Petermann's ammonium-citrate solution. (2) Dicalcium phosphate, prepared electrolytically (with sodium chlorate) from so-called "slig" (apatite, iron ore, etc.). It contained lime 38.53 per cent, phosphoric acid 39.91 per cent, citric-acid soluble phosphoric acid 37.23 per cent, and citrate-soluble phosphoric acid (Petermann's solution) 33.52 per cent. (3) Precipitated phosphate, essentially a mixture of dicalcium and tricalcium phosphates, with 41.36 per cent total and 24.12 per cent citrate-soluble phosphoric acid. (4) Steamed bone meal, containing 21.39 per cent total and 20.27 per cent citric-acid soluble phosphoric acid, with 4 per cent nitrogen. (5) Superphosphate (same as used in the first series) containing 17.6 per cent water-soluble phosphoric acid.

The field used for the experiments was a poor sandy soil, with 0.336 per cent lime, 0.025 per cent potash, and 0.039 per cent phosphoric acid (soluble in hot hydrochloric acid of sp. gr. 1.15). In order to further investigate the comparative effect of the different phosphates with or without an extra supply of lime in the soil (*E. S. R.*, 12, p. 323), applications of similar amounts of the different fertilizers were always made in duplicate, one series receiving lime and the other no lime. The crop used was oats, which were sown in glass cylinders, 49 cm. high and 24 cm. in diameter. The basal fertilization applied was at the rate of 300 kg. of potash, 100 kg. of nitrogen, and 33 kg. each of common salt and magnesium sulphate per hectare. The precipitated, dicalcic phosphates and superphosphate were added in three different quantities, viz, at the rate of 50, 100, and 150 kg. of citrate or water-soluble phosphoric acid, and the other phosphates at the rate of 100 kg. of phosphoric acid per hectare. Six parallel tests were made with each fertilization, of which 3 were made with lime (333 kg. of calcium carbonate in the form of finely powdered marble per hectare), and 3 without lime.

The results obtained showed that the liming in itself, without accompanying addition of phosphoric acid, produced a considerable increase in yield—on the average for all series, 100:163.1. The following statement presents the main average results of the trials, taking the results on the "no phosphoric acid" and "no lime" plats as 100:

Comparative effect of different phosphates, with and without lime, on oats.

	No lime.	Lime.	No lime.	Lime.
No phosphoric acid.....	100	163	100	163
50 kg. of phosphoric acid per hectare in superphosphate.....	1,002	1,013	100	101.3
100 kg. of phosphoric acid per hectare in superphosphate.....	1,038	1,060	100	102.3
150 kg. of phosphoric acid per hectare in superphosphate.....	1,092	1,071	100	97.9
50 kg. of phosphoric acid per hectare in dicalcium phosphate.....	1,010	926	100	90.7
100 kg. of phosphoric acid per hectare in dicalcium phosphate.....	1,032	1,010	100	97.7
150 kg. of phosphoric acid per hectare in dicalcium phosphate.....	1,027	1,042	100	101.6
100 kg. of phosphoric acid per hectare in precipitate.....	1,007	1,008	100	100.2
100 kg. of phosphoric acid per hectare in tricalcium phosphate.....	607	271	100	33.4
100 kg. of phosphoric acid per hectare in bone meal.....	790	229	100	18.7

The results of the trials corroborate those of Kellner and Böttcher in showing that the favorable effects of bone meal are considerably decreased by liming, viz, as much as 81 per cent. They also show that a similar decrease took place in case of precipitated calcium phosphate (66.5 per cent decrease). The results obtained differ from those of the scientists mentioned in so far as the effect of the superphosphate was not materially influenced by the addition of the lime, possibly because the author used less lime.

The effect of liming on the action of bone meal is discussed by the author. He calls attention to the fact that the fertilizing value of neutral phosphates only was reduced by the addition of lime, and suggests that the calcium bicarbonate formed in soils rich in lime by the action of water containing carbonic acid in solution on calcium carbonate may be responsible for the phenomenon, since the water containing this salt in solution does not dissolve tricalcium phosphate to the same extent as does water containing free carbonic acid.

The residuary effect of tricalcium phosphate was studied during 1901 with the cylinders used in the experiments of the preceding year. Although the phosphoric acid in the tricalcium phosphate only slightly improved the crop harvested during the first season, its effect during the following season was insignificant, and was decidedly less than during 1900 and less than the residuary effect of Thomas phosphate during the season of 1901.

As regards the value of the two electrolytically prepared phosphates, the conclusions drawn are that triphosphate on soils poor in lime produced somewhat lower results than did bone meal and on freshly limed soils somewhat better results, and that dicalcium phosphate proved to possess much the same fertilizer value as superphosphate, without regard to whether the soil was limed or not.—F. W. WOLL.

The action of phosphoric acid in the presence of lime, BACHMANN (*Fühling's Landw. Ztg.*, 52 (1903), No. 1, pp. 12-14).—Plat experiments with rye, oats, and beets on sandy soils fertilized with superphosphate, Thomas slag, and bone meal with and without the addition of lime are reported. The most profitable returns were obtained with Thomas slag, the least profitable with bone meal. The results showed in general that the use of lime in connection with superphosphate and bone meal resulted in little or no reversion of the phosphoric acid during the first year.

The effect of moisture on the availability of dehydrated phosphate of alumina, F. W. MORSE (*Jour. Amer. Chem. Soc.*, 25 (1903), No. 3, pp. 280-288).—It is stated that a patented process for preparing dehydrated alumina and iron phosphate for use as a fertilizer by heating to about 325° C. was described by S. L. Goodale in 1893. Dehydrated phosphate shows a high solubility in ammonium citrate, although pot and field tests have not borne out the laboratory indications of availability. An account is here given of determinations of the progress of dehydration of Redonda phosphate heated to different temperatures—100, 150, 250, 325, 560, 830° C.—of the absorption capacity for water of the different samples so heated, and of the solubility in neutral ammonium citrate of the phosphoric acid of the undehydrated and dehydrated material as well as of samples which had been dehydrated at different temperatures and then allowed to absorb moisture. The results indicate that dehydration is not complete at 325° C., but that a temperature of 560° gives a product which is completely dehydrated, absorbs water more slowly, and for this reason remains soluble in ammonium citrate longer than phosphate heated to lower temperatures. Whether this resistance to hydration will render the phosphate actually more available to plants remains to be determined.

The action of phosphatic fertilizers on the chemical composition of forage plants, L. BONETAT and P. TOUCHARD (*Jour. Agr. Prat.*, n. ser., 5 (1903), No. 11, pp. 343-345).—The results of a number of experiments with grasses and leguminous plants are reported to show that the application of phosphatic fertilizers not only

improves the yield and quality of the forage, but increases their phosphoric acid content.

Pot experiments with nitrogenous fertilizers in 1901, C. S. PHELPS (*Connecticut Storrs Sta. Rpt. 1901*, pp. 154-164).—This is a report of a continuation of experiments carried on for several years (E. S. R., 13, p. 935). The results of pot experiments during 1901 with meadow fescue, Hungarian grass, barnyard millet, and soy beans are reported in detail. "The purpose of the pot experiments was to study the effects of nitrogenous fertilizers on the percentages of nitrogen and protein in some of our common farm crops. In this respect they are similar to the field experiments with nitrogenous fertilizers which the station has conducted during the past 12 years. . . . The results of the past 3 years' experiments indicate that our common grasses, such as orchard grass and meadow fescue, are greatly increased in the percentages of nitrogen and of protein by the nitrogen used as a fertilizer. Similar results were obtained with Hungarian grass and millet. The only cereal that has been grown in these experiments is oats. While the experiment has not been fully satisfactory, the increase in percentage of protein was much larger where the larger quantities of nitrogen were used as fertilizer. The only legume which has been successfully grown is the soy bean. The seed of this plant was but little increased either in total weight of crop or in the percentage of nitrogen by the nitrogen used as fertilizer."

Nitrate of soda and sulphate of ammonia, L. GRANDEAU (*Jour. Agr. Prat.*, n. ser., 5 (1903), No. 10, pp. 308, 309).—The relative fertilizing effect of these two sources of nitrogen as indicated by experiments by Wagner and the author is discussed. Wagner's experiments, which have extended over a number of years, indicate that the nitrogen of sulphate of ammonia is about 90 per cent as effective as that of nitrate of soda. The author's experiments give considerably lower figures for the nitrogen of sulphate of ammonia, namely, 86 per cent, falling to 80 per cent in soils very poor in lime and to 63 per cent in soils very rich in lime.

The action of 40 per cent potash salt and kainit on summer crops, H. BACHMANN (*Deut. Landw. Presse*, 30 (1903), No. 15, p. 120).—The results of the experiments with various crops here reported indicate that when applied in the spring the 40 per cent salt was in the majority of cases somewhat superior to kainit, but that the latter had a more lasting effect. With winter applications the kainit for the latter reason gave better results, especially on beets. At local market prices the kainit was more economical than the 40 per cent salt.

Top-dressing with potash on sandy soils, BACHMANN (*Fühling's Landw. Ztg.*, 52 (1903), No. 3, pp. 102, 103).—Good results were obtained with rye even when the top-dressing was delayed until the end of May. The results, however, were not as good as when the potash salt was applied before seeding.

Dried blood, E. M. PAGET (*Amer. Fert.*, 18 (1903), No. 2, pp. 5-7).—The details of the preparation of this product are described.

Concentrated tankage, E. M. PAGET (*Amer. Fert.*, 18 (1903), No. 3, pp. 14-17, figs. 2).—The methods of preparing this fertilizing material are discussed.

Report of observations on the peat industry in Canada, J. G. THAULOW (*Indberetning om en med offentlig stipendium sommeren 1901 foretaget reise for at studere torvdrift i Kanada m. fl. lande*. Christiania, 1902, pp. 26, pls. 8).

Report of observations on the peat industry in European countries, A. DAL (*Indberetning om en reise sommeren 1901 for at studere torvdrift i forskjellige europeiske lande*. Christiania, 1902, pp. 20, pls. 10).

On the composition and use of flotsam, F. P. BONUCELLI (*Staz. Sper. Agr. Ital.*, 36 (1903), No. 1, pp. 5-24).—The fertilizing value of the refuse (leaves and similar material) which accumulates at certain points along the banks of streams and shores of other bodies of water is discussed and numerous analyses are reported.

Analyses of commercial fertilizers, M. A. SCOVELL and H. E. CURTIS (*Ken-*

tucky Sta. Bul. 104, pp. 247-281).—Analyses of 334 brands of commercial fertilizers examined during 1902 are reported, with a brief discussion of methods and results of the inspection.

Analysis of commercial fertilizers sold in Maryland, H. B. McDONNELL ET AL. (*Maryland Agr. College Quart., 1903, No. 19, pp. 48*).—The results of analyses of 498 samples of fertilizers examined from August, 1902, to January, 1903, are reported.

Analyses of licensed fertilizers, 1902, F. W. WOLL and G. A. OLSON (*Wisconsin Sta. Rpt. 1902, pp. 247-250, 285, 286*).—Analyses of 11 samples are reported, with brief notes on the results of inspection. The text of the State fertilizer law is also given.

Fertilizers licensed for sale in Wisconsin in 1903, F. W. WOLL (*Wisconsin Sta. Bul. 99, pp. 5, 9, 10*).—The text of the State fertilizer law is given, with guaranteed composition of 13 brands of fertilizers licensed for sale in 1903.

FIELD CROPS.

Field experiments with fertilizers, C. S. PHELPS (*Connecticut Storrs Sta. Rpt. 1901, pp. 122-147*).—The work here reported comprises special nitrogen experiments with corn, cowpeas, and soy beans, and a soil test with different fertilizers on crops grown in rotation. The work is repeated yearly with the same fertilizers on the same plats. The reports of former years together with a description of the experiments have been previously noted (*E. S. R., 12, p. 936*).

The results with corn indicate that mineral fertilizers are very essential to the crop but insufficient when used alone. The complete fertilizer was found essential for good yields. The most profitable results, considering the yields alone, were obtained with 25 to 50 lbs. of nitrogen per acre in the form of nitrate of soda used with mineral fertilizers. When the feeding value of the crop is taken into consideration even larger quantities of nitrogen than 50 lbs. per acre are believed to be profitable. The use of nitrogen beyond 50 lbs. per acre did not generally produce a marked increase in the dry matter but the percentages of nitrogen and of protein in the grain and the stover were highest where the largest quantities of nitrogen had been used in the fertilizers.

Experiments with cowpeas and soy beans show that mineral fertilizers are effective in increasing the yields. The addition of nitrogenous fertilizers had but little effect on the yield or the percentage of protein in the crop. The average results of the experiments thus far made at the station with cowpea fodder show practically no advantage over the use of nitrogenous fertilizers. With soy beans the use of nitrogen in the fertilizer application produced a small increase in the yield of seed. In both crops the protein was increased but little, if any, by the use of nitrogenous fertilizers.

The results of the soil test with crops in rotation for 1901 showed that while the mineral fertilizers were of greater value than nitrogen in increasing the yield of soy beans, nitrogen was of more value when supplied in the form of manure. While a complete fertilizer gave an increase of only 2 bu. per acre over the yield where only mineral fertilizers were used, manure gave an increase of nearly 9 bu. The general results for the past 12 years show that nitrogen and phosphoric acid are of prime importance on the station soil for good yields of oats. These same elements were most effective where corn was grown in rotation. Potatoes responded more generally to the use of potash.

Fertilizer experiments with wheat and barley, G. P. FOADEN (*Jour. K. h. div. Agr. Soc. and School Agr., 4 (1902), No. 5, pp. 177-183*).—Cooperative experiments were conducted to test the value of nitrate of soda, superphosphate, and barnyard manure as fertilizers for wheat and barley. The results indicate that on land of

moderate quality nitrate of soda was an effective and profitable fertilizer for wheat. Barnyard manure did not appear remunerative, probably because the application did not have sufficient time to become effective, and for this reason barnyard manure is considered better adapted to the cotton crop. The increase in yield due to the use of superphosphate was not adequate to repay the cost of the fertilizer.

Relation of crop production to amount of water available and methods of cultivation, A. R. WHITSON (*Wisconsin Sta. Rpt. 1902, pp. 184-191*).—This work is in continuation of rotation and irrigation experiments previously noted (*E. S. R.*, 13, p. 936). The yields of the different crops are given, and the distribution of rainfall during the growing season for 21 years is shown in a table. The rotation is oats seeded to clover, clover, potatoes on manured clover sod, and corn. The rainfall was so plentiful this season that irrigation became unnecessary.

The results with corn showed that the growth of ears and stalks were greater during the wet and cold season of 1902 than during the hot and dry season of 1901, when the deficient rainfall was supplemented by irrigation. In 1902 larger yields of corn were obtained from manured and unmanured plats which had never been irrigated than from similar plats which had been irrigated in previous years. This result is considered due to the reduction of fertility by the growth of larger crops under irrigation during the dry season, or to the washing of the irrigated soil.

The yield of potatoes was smaller than the year before when the ground was irrigated. Potatoes grown in rotation yielded 342.8 bu. per acre, while a crop on old alfalfa sod, but otherwise treated the same, gave only 277.7 bu. per acre.

The author assumes that under the existing climatic conditions 18 in. of rainfall during the growing season is sufficient for corn and potatoes, 12 in. for oats, and 24 in. for hay. On this basis there has been a shortage of 4 in. or more in 10 of the past 21 years during the corn and potato season, in 12 years during the hay season, and in 4 years during the oat season.

The results of an experiment showed that the soy bean plants used 527 lbs. of water per pound of dry matter produced. In previous determinations made at the station it was found that corn used 270.9 lbs. of water per pound of dry matter produced, oats 503.9 lbs., and clover 576.6 lbs. The soy beans yielded 7,980 lbs. of dry matter per acre, equal to 9,177 lbs. of hay with 15 per cent of moisture, and the quantity of water used was 18.68 in.

Influence of the soil on the protein content of crops, A. R. WHITSON, F. J. WELLS, and A. VIVIAN (*Wisconsin Sta. Rpt. 1902, pp. 192-209, figs. 5*).—Experiments were conducted in the field and the plant house to determine the influence of the soil on the protein content of corn, oats, barley, rape, and cowpeas. The nitrate was furnished the soil in some instances as a solution of nitrate of soda and in others as leachings from a very rich soil. In each test the amount of nitrate in the soil was determined at 2 or 3 stages previous to and at the time of making the determination of the protein in the plant. The results obtained by other workers along this line have been previously noted.

Oats were sown in jars on March 29 and the soil in some jars watered with lake water containing no nitrates, in others with an amount of leachings of a rich plant-house soil with the lake water, and in a third group with the same leachings twice as strong. It was found that the amount of nitric nitrogen in the plant decreased greatly between May 6 and 21 in the plants growing in the poorest soil, while it increased slightly in the plants growing on soil of medium fertility, and much more in those on the richest soil. The proteid nitrogen in the entire plant May 21 on the poorest soil amounted to 1.93 per cent, on the medium soil 2.53 per cent, and on the richest soil 2.66 per cent. The percentage of protein was 31.09 larger in the crop grown on ground of medium fertility and 37.8 larger in the crop grown on the most fertile soil than in that on the poorest soil.

Rows of oats and rape were planted on 3 sandy plats in the plant house on March 15. The first received no fertilizer, the second a small amount of sodium nitrate, and the third double this amount. The nitric nitrogen in the plants decreased from the first in those receiving no fertilizer, increased rather strongly in the second plat at first but decreased largely as the plants matured, while the third plat showed a slight decrease toward the end. On June 6, when the oats were in bloom, the percentage of proteid nitrogen on the first plat was 1.29, on the second plat 1.63, and on the third 1.70, corresponding to 8.06, 10.19, and 10.63 per cent of protein, respectively. This shows a gain in the percentage of protein of 26.3 for the smaller amount of nitrate fertilizer, and 31.88 for the larger amount. The analyses of the ripe seed taken July 1 show a percentage of proteid nitrogen of 2.57 on the first plat, 2.79 on the second, and 2.77 on the third.

Corn was grown in the field on manured and unmanured plats and on soil planted to potatoes on clover sod the year before. There was a considerable difference in the amounts of nitric nitrogen in the soil water of the manured and unmanured plats as determined July 8 and 29. This result is considered due to the actual difference in the soil fertility, the growth of the crop, and leaching rains. The amount of nitrates was largest in the unmanured soil and the percentage of nitrates and of proteid nitrogen in the plant was also greater on the unmanured land. The manure decreased the percentage of protein in the crop but produced the greater total amount. "Contrary to the general rule, the plants which made most vigorous growth contained the smaller percentage of protein. It would seem that the stimulating influence of the manure had been chiefly due to something other than the nitrogen it contained, or at least to the nitrogen supplied the plant in the form of nitrates." Corn following potatoes on clover sod in rotation contained a larger percentage of protein than the crop from the manured plat. Corn grown near trees contained 0.97 per cent of proteid nitrogen on August 18 as compared with 1.31 per cent in corn not affected by trees. On September 5 the result was 0.86 and 1.09 per cent, respectively.

An experiment with corn grown with oats and rape was made in the plant house on 3 plats arranged and treated as described under the experiments with oats. "The results of this experiment would point toward four conclusions: (1) That the percentage of protein in the plant is dependent directly on the amount of nitrates in the soil; (2) that corn on different fields may make very nearly equal growth while differing materially in percentage of protein produced; (3) that beyond a certain point the percentage of protein is not increased by excess of nitrates; and, (4) that in the presence of a sufficient amount of nitrates in the soil, variations in the growth of the plant are caused by the amounts of salts in the soil other than nitrates." The corn on plat 1 contained 8.44 per cent of protein; on plat 2, 9.94 per cent; and on plat 3, 11.25 per cent.

Cowpeas were grown in jars under the treatment that was given oats grown in the same way. The fertilizers applied produced a greater effect on the growth of the plants with cowpeas than with any other crop in these experiments. The percentage of nitric and proteid nitrogen in the dry matter was largely in favor of the plants having received the largest amounts of fertilizer. The soil did not contain tubercle-forming bacteria, and plants inoculated about August 1 on the South Carolina cowpea soil had their roots well covered with tubercles when examined in October. In a field test cowpeas were grown on an inoculated and on an uninoculated plat. The inoculated plat had produced a crop of cowpeas the year before. The nitric nitrogen in the plants from the inoculated plat on August 15 amounted to 0.691 per cent and in those from the uninoculated plat 0.265 per cent. In samples of the entire plant above ground taken September 13 there was a difference of 48 per cent in the proteid nitrogen in favor of the inoculated plat. The causes to which this difference is due are as yet undetermined.

Rape grown indoors under the same conditions as oats and corn showed an increase of 11.40 and 13.445 per cent of protein on the second and third plats, respectively, as compared with the first plat which received no fertilizer. The results indicate that the amount of nitric nitrogen given the second plat was apparently all that the plant could utilize in the formation of protein.

Experiments with grain and forage plants, 1902, R. A. MOORE (Wisconsin Sta. Rpt. 1902, pp. 217-240, figs. 4).—An account is given of the weather conditions of the season and of the results obtained in the culture of a number of varieties of grains. Severe storms in June and July injured the small grains grown to such an extent that data as to yields per acre, etc., have been omitted from the report. Of 11 varieties of barley grown, Manshury and Oderbrucker, both 6-rowed varieties, led in yield and general excellence. Seventeen varieties of oats were grown, and of these Swedish oats have given the best results for a period of 4 years. In many instances the yield with this variety has exceeded 80 bu. per acre. This variety of oats was obtained through the U. S. Department of Agriculture, and it is believed that its introduction in Wisconsin will raise the average yield several bushels per acre. Petkus and Schlansted, varieties of rye imported from Germany, have yielded from 29 to 41 bu. per acre during 2 seasons.

From 2 to 10 tons of green forage or 2 to 3 tons of cured hay have been obtained from an acre of soy beans at the station. The station experiments indicate that soy beans for hay in that region should be sown broadcast at the rate of about 1 bu. of seed per acre, and the crop cut on the appearance of small pods. If seed is desired it is best to sow the grain in drills 30 in. apart, dropping the seed about 4 in. apart in the row. It can be planted later in the season and appears to give better results at the station than cowpeas. Very good results were obtained when the soy beans were planted with corn for silage. Out of 8 varieties of soy beans tested Medium Early Yellow gave the highest yield, 38 bu. per acre, followed by Ito San, 33.7 bu. per acre, and Michigan Green, 26.7 bu. per acre. The growing period of the first two was 136 days and of the last 162 days. No tubercles were produced on the roots of the soy beans grown at the station until after the soil had been inoculated. Six varieties of cowpeas were grown at the station to determine their value for forage and seed production. The varieties Red Ripper and New Era gave the best returns, yielding 10.8 and 13.7 bu. per acre, respectively. The varieties did not ripen evenly and a number of the varieties sown failed to ripen seed at all.

Common varieties of alfalfa at the station have quite generally winterkilled and in other instances have been crowded out by weeds and grass. Turkestan alfalfa has proved much hardier and given better results. The best results were secured when the Turkestan alfalfa was seeded with oats as a nurse crop. The oats were sown at the rate of about 1 bu. per acre and seemed to aid in keeping down the weeds. Cutting alfalfa earlier than it is usually cut for hay seemed to have a detrimental effect upon the crop, reducing the yields. Three crops were cut during the season and gave an average total yield of 4.5 tons of hay per acre. An effort was made to produce seed from the second cutting but only an occasional seed was formed, though the plants flowered profusely. Summing up the results obtained with alfalfa, the author believes that to obtain a good catch in Wisconsin the crop should be seeded in the spring on fall-plowed land as soon as the ground can be put in good condition. If the ground is inclined to be weedy it should be seeded with a nurse crop of oats. Should the oats be inclined to lodge they should be cut, as otherwise they will smother the alfalfa. On very clean ground alfalfa may be sown without a nurse crop.

A test was made of 16 varieties of clover. Of this number Missouri, Minnesota, Nebraska, Michigan, and English No. 12,174 gave the best results. Hungarian grass (*Bromus inermis*) has been found to start 2 weeks in advance of the more common grasses and to furnish pasturage 2 or 3 weeks longer in the fall. The hay pro-

duced is inferior to that of timothy and the yield is not as heavy. In dry weather it withers and remains dormant several weeks.

Hairy vetch gave a cutting of 3 tons of hay per acre. On the rich soil of the station it is inclined to lodge badly. Its trailing nature makes it difficult to harvest and causes the portions next to the ground to decay, making them unfit for stock. It makes a fine fall and early spring pasture when sown with winter rye.

Flax was sown during the season, but was destroyed by an undetermined disease. Early Amber sorghum, seeded July 18, in rows 18 in. apart, at the rate of 2 pk. of seed per acre, yielded about 9.75 tons of cured forage per acre. It has been a very satisfactory soiling crop for cows, but should not be cut until it begins to tassel, as previous to that time it is not so palatable to stock.

Experiments in treating oat seed for smut with 1 lb. of formaldehyde to 50 gal. of water, 1 lb. to 25 gal. of water, and 1 lb. to 10 gal of water, respectively, indicate that none of these strengths is injurious to the germinating properties of the seed. Any of these solutions is a very effective remedy against oat smut. The seed should be submerged in the solution for at least 20 minutes and then spread out to dry. Wet seed will not work well in a grain drill, but if it must be used the drill should be set to sow 1 bu. more per acre than when sowing dry oats.

Work in plant breeding at the station under way is briefly noted.

Cultivated forage crops of the Northwestern States, A. S. HITCHCOCK (*U. S. Dept. Agr., Bureau of Plant Industry Bul. 31, pp. 28, pls. 7*).—This bulletin presents a brief discussion of the forage resources in that portion of the country extending from Colorado and central California to Montana and Washington. This area is divided into the Great Plains, Rocky Mountain, Great Basin, Interior Valley of California, upper Pacific coast, and Palouse regions. The forage conditions in these different regions are considered separately. The crops of greatest importance are alfalfa, timothy, redbud, awnless brome grass, velvet grass, and clovers, and those of minor importance, Kentucky blue grass, orchard grass, cheat, perennial rye grass, rape, field peas, and vetches. The value of each of these crops is pointed out. Alfalfa is discussed at some length with reference to its general conditions, its feeding value, and the methods of seeding and hay making. Notes are also given on the use of grain for hay and the methods and advantages of baling hay.

Alfalfa, its chemical development, H. SNYDER and J. A. HUMMEL (*Minnesota Sta. Bul. 80, pp. 149-171, figs. 6*).—A description of alfalfa is given, together with directions for the culture of the crop. The observations of a number of farmers with reference to alfalfa growing are reported.

The chemical development of the plant was studied at the station. Samples of 1 sq. yd. each of Western alfalfa were taken on June 3, 10, and 24, and of Turkestan alfalfa on June 3 and 10, and analyzed. The samples taken June 3, when the first blossoms were just appearing, contained the highest percentage of total nitrogen and proteid nitrogen and the least percentage of fiber. The results of the analyses and the number of grams of nutrients yielded by 1 sq. yd. at the different stages are tabulated.

Analyses of similar samples of the second crop taken June 30 and July 7, 14, 22, and 29 in general corroborate the results of previous experiments. The total nitrogen and ether extract decreased regularly and the fiber increased as the growth of the crop progressed. "The crop reaches the condition most suitable for cutting at the time when one-third of the blossoms have appeared. After this a larger amount of much inferior hay is obtained."

The proportion of dry matter in the leaves and stems was determined in samples taken at intervals of 4 days from June 3 to June 30. The analyses of the dry matter of these samples is given in the following table:

Analyses of the dry matter of the leaves and stems of alfalfa at different stages of growth.

	Time of cutting samples.						
	June 3.	June 7.	June 11.	June 16.	June 21.	June 25.	June 30.
Leaves:	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Dry matter	24.90	30.84	28.26	32.44	34.18	32.70	59.10
Total nitrogen	4.36	3.66	3.73	3.12	2.74	2.74	2.77
Proteid nitrogen	3.69	3.02	3.33	2.51	2.17	2.18	2.17
Per cent proteid to total nitrogen	84.69	82.74	89.20	80.66	78.95	79.44	78.25
Crude protein (total nitrogen \times 6.25)	27.25	22.87	23.31	19.50	17.12	17.12	17.81
Ether extract	2.56	4.48	4.48	3.80	6.12	5.45	4.56
Fiber	12.76	13.04	17.80	13.37	17.89	18.89	20.05
Ash	7.83	6.54	7.31	7.75	8.35	7.66	8.52
Stems:							
Dry matter		25.84	23.66	30.21	32.65	32.84	58.90
Total nitrogen	1.95	1.76	1.88	1.59	1.65	1.60	1.46
Proteid nitrogen	1.32	1.23	1.46	1.24	1.35	1.40	1.28
Per cent proteid to total nitrogen	67.77	69.77	77.43	78.00	81.96	88.47	87.60
Crude protein (total nitrogen \times 6.25)	12.18	11.00	11.75	9.94	10.31	10.00	9.13
Ether extract	1.19	.78	1.66	1.95	2.53	2.48	3.19
Fiber	50.76	48.13	46.69	48.21	48.16	48.12	55.15
Ash	6.79	5.56	5.62	5.36	6.00	4.98	4.61

About June 11, after the plants had begun to blossom, part of the leaves began to turn yellow and to fall, hence the largest proportion of leaves to stems existed just before the blossoming period. The leaves of the sample taken when the blossoms appeared contained 23.06 per cent of crude protein. On June 3 the leaves contained 63 per cent of the nitrogen in the part of the plant above ground, but by June 11 this percentage had fallen to 57. The dry matter increased quite regularly in both leaf and stem as the season progressed. In the leaf both total and proteid nitrogen decreased as the plant ripened, the proteid nitrogen decreasing more rapidly. The ether extract increased in both leaves and stems, but rather irregularly in the leaves, while the fiber increased in the leaves, but remained almost the same in the stems. The percentage of ash or mineral matter decreased in the stems, but remained almost stationary in the leaves. The results of the ash analyses of leaves and stems procured at different dates are given in tables. From these analyses it is shown that an average yield per acre of 8,000 lbs. of cured hay, which will contain about 6,880 lbs. of dry matter, removes from the soil 206 lbs. of potash, 58 pounds of phosphoric acid, 89 lbs. of lime, and 22 lbs. of magnesia. The ash of alfalfa seed contained 32.77 per cent potash and 44.29 per cent phosphate. The composition of the dry matter of the roots, blossoms, young plants, the first and second crops, and the seed is reported.

Variety tests with barley, C. SONNE (*Tidsskr. Landbr. Plantearl*, 8 (1902), pp. 47-60; 9 (1902), pp. 99-114).—The work here reported is conducted by the Royal Agricultural Society of Denmark on 5 different farms and has been in progress for 5 years. The average yield per acre for this period for the different varieties was as follows: Prentice 2,380 lbs., Chevalier 2,210 lbs., Goldthorpe 2,030 lbs., Erh. Frederiksen Hybrid 1,977 lbs., and Imperial 1,671 lbs. According to a scale of 20 points for perfection these varieties scored 14.4, 15.5, 17.9, 15.0, and 16.1 points, respectively. The results were not materially changed when the data for the season of 1901 were also included in the summaries.—F. W. WOLL.

Commercial bean growing in New York, J. L. STONE (*New York Cornell Sta. Bul.* 210, pp. 231-254).—This bulletin includes an historical account of bean culture; statistics of bean production taken from the Twelfth Census; complete directions for growing the crop, and a report on variety, fertilizer, and soil tests conducted by the station. The diseases and insect enemies of the bean plant are briefly noted.

Cooperative variety tests were conducted for 3 years. Taking the average results into account, the most productive varieties were Blue-pod medium, Marrow pea, Day

leafless medium, and Boston small pea. The yields of straw in some of the variety tests were also reported. The results varied considerably in different localities. In a number of tests to determine the adaptation of the variety to the soil it was found that in general the best yields were obtained on the lighter soils. From these experiments it is concluded that there is a great difference in the productivity of the different varieties on a given soil and that the results in a variety test may not be applicable to other localities.

Fertilizer experiments were made with different combinations of commercial fertilizers and with barnyard manure. The results are reported, but are considered as not leading to satisfactory conclusions. Phosphoric acid in the form of South Carolina rock is believed to be more likely to give profitable results than any other application.

The composition of cull beans as determined by the station chemist is compared with the composition of oats, gluten feed, and corn, and the digestible nutrients in bean straw are given with those of timothy hay, corn stover, and oat straw.

Flax culture, R. KUHNERT (*Der Flachsbau*. Berlin: Deut. Landw. Gesell., 1903, pp. VIII + 23).—This book is a brief popular account of the culture and preparation of flax and the cost of its production.

Corchorus, jute, or gœni, H. J. WIGMAN (*Teysmannia*, 12 (1902), No. 12, pp. 616-621).—The author calls attention to jute culture in Java and thinks the importance of the subject warrants him in reproducing portions of a paper by J. A. B. Wiselius, published in a report of 'S Lands Plantentuin in 1886. Two species are grown for fiber, *Corchorus capsularis* and *C. olitorius*, the latter yielding the better product and being grown on low lands, while the former is better adapted to higher situations. The best lands for jute culture are those that are never under water but always moist, though much is grown on land covered with shallow water, or on land on which periodic floods leave a layer of silt.

The seeds germinate promptly and the plants are ripe in 4 months after the seed is sown. If the crop is cut too early the fiber is weak, while if the plants are allowed to bloom the fiber loses its gloss and becomes too stiff. The methods employed to separate the fiber from the rest of the plant are described. The culture of jute is said to be profitable for the small planter who does much of the work himself, but when all of the work must be paid for there is little profit.—H. M. PIETERS.

Variety tests with oats, K. HANSEN (*Tidsskr. Landbr. Planteavl*, 9 (1902), pp. 203-261).—The best yielding and most satisfactory varieties of oats tested at the different Danish plant culture stations were the Grenaa or Hessel and the Island or Førslev. The author believes these two kinds to be one and the same variety, since they correspond closely in all essential characteristics and appear to have originated in one locality, and he therefore proposes the name Danish oats for the same. On good and medium soils these oats in nearly all trials yielded about 1 cwt. more grain per tøndeland (1.36 acres) than the Beseler and about 2 cwt. more than Ligowo. On light, dry, sandy soils Grey oats gave practically the same results as the Danish oats.—F. W. WOLL.

Potato culture, A. AGEË (*Pennsylvania Dept. Agr. Bul.* 105, pp. 96).—This bulletin is a popular treatise on potato culture, discussing at some length the soil and its preparation, the seed, planting, cultivation, harvesting, storing, insect enemies, diseases, and the use of potatoes for food.

Variety tests with potatoes, 1881-1898, A. J. HANSEN (*Tidsskr. Landbr. Planteavl*, 8 (1902), pp. 167-189).—Reports of 4 series of potato experiments conducted at Danish experiment stations since 1881, with summaries.—F. W. WOLL.

Spelt, emmer, and einkorn, P. HAUPTFLEISCH (*Landw. Vers. Stat.*, 58 (1903), No. 1-2, pp. 64-136, figs. 29).—This article discusses the distribution and culture of these cereals; describes the different varieties under each species; presents a study of the anatomical structure of the kernels; gives the chemical composition of the

grain, bran, and meal as determined by different investigators; outlines the milling processes by which bran and meal are obtained, and reports the results of a microscopical investigation of these products.

Sugar-beet experiments during 1902, F. W. WOLL and R. A. MOORE (*Wisconsin Sta. Rpt. 1902*, pp. 241-246, fig. 1).—Beets were grown on well-prepared rich soil. The season was very favorable and the yield obtained was at the rate of nearly 30 tons of beets per acre. The largest yield ever obtained at the station before was in 1890, when a yield of nearly 20 tons was obtained. It is believed by the author that there are few crops grown in Wisconsin that will pay better through a series of years than sugar beets. Analyses of the beets grown are given in tables.

The leaf in its relation to the sugar content of the beet, H. PLAHN (*Fühling's Landw. Ztg.*, 52 (1903), No. 1, pp. 30-33).—The influence of the leaf on the formation of sugar in the beet is discussed and the results of observations made along this line are reported. In the greater number of beets examined the weight of the root was from 3 to 5 times the weight of the leaves. The beets with the relatively highest weight of leaves were richest in sugar.

Fertilizing and planting sweet potatoes, M. B. WAITE (*Amer. Agr.*, 71 (1903), No. 13, p. 359).—The author plants sweet potatoes in drills 4 ft. apart, ridging them up after manuring and fertilizing, and setting the plants on the top of the ridges. The fertilizer is applied in the drill after laying off at the rate of about 1,000 lbs. per acre, using a mixture of 1,000 lbs. acid phosphate, 400 lbs. sulphate of potash, 100 lbs. dried blood, 100 lbs. nitrate of soda, and 400 lbs. bone tankage. The plants are set on a warm day. They are dipped first, in hands of 1 to 2 doz., into a soft mud batter about as thick as good thick cream, and set deeply.

Macaroni wheats, T. L. LYON (*Nebraska Sta. Bul. 78*, pp. 24, fig. 1).—The appearance and habits of growth of macaroni wheats are described and the foreign and home market demands discussed, in addition to a report on cooperative culture and variety tests. About 100 tests throughout the State were made with 11 varieties obtained from Russia and Algeria. The average time of ripening for the different sorts was July 16. The date of sowing did not influence the date of ripening. The average yield of sowings made before April 1 was 19.5 bu. per acre and for those made after that date 17.5 bu. Omitting varieties with less than 5 tests, the Russian varieties averaged 21.2 bu. per acre and the Algerian 17.6 bu. From the results at hand it is concluded that durum or macaroni wheats yield better than other spring varieties. Seventeen varieties were tested at the station. The results did not indicate the variety best adapted to Nebraska conditions, but the superiority of the Russian over the Algerian sorts was shown.

HORTICULTURE.

Field experiments on the manuring of vegetable and fruit crops, F. W. E. SHRIVELL and B. DYER (*London: Vinton & Co., Ltd., 1902*, pp. 88).—The experiments here recorded were made to determine the relative economy in vegetable and small fruit growing of applying manure at the rates of 12½ and 25 tons per acre alone and of supplementing the manure with varying amounts of complete commercial fertilizers or with commercial fertilizers containing but 1 or 2 of the essential elements. It was intended to learn also how far with economy commercial fertilizers can be made to take the place of manure and whether or not it is possible to dispense with manure altogether, using commercial fertilizers instead. Another phase of the question investigated was to determine the most economical amount of nitrate of soda to use with other fertilizers in manuring. The experiments for the most part have been under way for 7 years. The present report includes summaries of the results secured during the current year and of the collective results thus far secured with artichokes, Jerusalem artichokes, asparagus, beans, beets, Brussels sprouts, broccoli,

cauliflowers, cabbages, carrots, celery, lettuce, onions, potatoes, peas, rhubarb, spinach, strawberries, gooseberries, and alfalfa.

The soil used for the experiments is a rather poor clay loam resting upon a bed of heavy clay. By spade culture and heavy manuring it has been converted into a fertile market-garden soil. The results obtained in the different experiments as a whole go to show that the purchase of manure for many crops is highly extravagant, as its place can well be taken by cheaper commercial fertilizers, while for many other crops manure is advantageous, but the enormous quantities often applied are altogether too costly and should be replaced in part by fertilizers in the more concentrated form. In general, the smaller amount of manure used in these experiments supplemented with commercial fertilizers has given the best results. Potash has been found especially desirable in the culture of Globe artichokes. The use of 100 lbs. of sulphate of potash per acre increased the value of the early product nearly \$40.

Asparagus grown with the aid of commercial fertilizers has been more tender and of a better flavor and quality than that grown with manure alone. It is recommended that the manure and also the superphosphate and kainit for asparagus be applied in the latter part of the winter or in very early spring. On the whole, it is considered that with asparagus the best crops have been grown by using the lesser amount of manure supplemented by a dressing of phosphates, kainit, and 400 lbs. of nitrate of soda per acre.

With beets, sulphate of potash in the absence of manure increased the yield 3 tons per acre. In every case plats fertilized with the lesser amount of manure and commercial fertilizers greatly exceeded in yield the heavily manured plats.

With broccoli, a moderate application of commercial fertilizers has produced on the average as good results as when supplemented by 12½ tons of manure. With this crop the use of 100 lbs. of nitrate of soda per acre proved most economical.

The average results for 5 years with cauliflowers show that 12½ tons of manure, supplemented with a light dressing of phosphates and 400 lbs. of nitrate of soda, produced better results than commercial fertilizers alone, but the commercial fertilizers alone gave better results than 25 tons of manure alone. Commercial fertilizers in this case not only increased the size of the heads, but uniformly improved the quality. The formula recommended for this crop is 12½ tons of manure, 400 to 600 lbs. of superphosphate, 400 lbs. of kainit, and 400 lbs. of nitrate of soda per acre.

The heaviest yield of Brussels sprouts was obtained by the use of 25 tons of manure, supplemented with 200 lbs. of nitrate of soda, with potash in addition.

A moderate quantity of manure was found very desirable with fall-set cabbages. It is recommended that this be supplemented with 600 lbs. of good phosphates per acre and nitrate of soda up to 600 lbs. applied at 2 or 3 different times. For spring-set cabbages manure has not been found necessary. It is recommended that they be planted out after the removal of some other crop that has been manured, giving a liberal dressing of superphosphate and potash.

Potash has been found very desirable in the production of carrots. When potash has been used in connection with phosphates and 200 lbs. of nitrate of soda per acre, the average yearly increase of roots has been nearly 3 tons per acre.

The heaviest celery plants were obtained when the largest amount of manure was used, but plants raised with the aid of commercial fertilizers have been much crisper and more tender than plants grown with manure alone. Nitrate of soda appeared to render the growth more rapid and to diminish the strength and toughness of the fibrovascular bundles as compared with plants grown by the aid of manure alone.

With lettuce also it has been noticed that plants grown with the nitrate of soda have been much crisper and more tender than those grown with manure alone.

With spring or summer onions the use of 200 lbs. of nitrate of soda per acre, in conjunction with potash and phosphates, with a light dressing of manure, has given a better yield than with a heavy dressing of manure. Commercial fertilizers without the manure gave much less satisfactory results than with the manure.

With parsnips, as with carrots, potash seems to be especially desirable, the yields being increased from 1 to 1½ tons per acre when this fertilizer was used over plats similarly fertilized but without potash.

In the case of early potatoes the heaviest yields have been obtained by the use of 25 tons of manure per acre. With the late crop better yields have been obtained by using half this amount of manure, supplemented with commercial fertilizers. In the experiments with potatoes the use of potash has regularly resulted in increased yields. The increase, however, has been much less with early potatoes than with late potatoes.

Potash has proved especially desirable for summer spinach, and particularly so on plats which were not manured.

The use of 200 lbs. of nitrate of soda per acre with phosphates and potash for alfalfa resulted in increasing the yields on the average nearly 4 tons per acre. Nitrate of soda was also found especially desirable in the growth of dwarf beans, improving the quality and increasing the weight 80 per cent.

Rhubarb dressed with commercial fertilizers when raw was far more crisp and tender and required less time to cook than rhubarb grown by the aid of manure alone.

The flavor and keeping qualities of strawberries were also decidedly better on moderately manured plats treated with commercial fertilizers, including a moderate dressing of nitrate of soda, than on either heavily manured or heavily nitrated plats. Moderate manuring, supplemented by phosphates and 200 lbs. of nitrate of soda per acre, is recommended for this crop. The nitrate of soda should be applied early in the year. In the light of the experimental results obtained with this crop it is recommended that potash be omitted from the fertilizers applied. When this fertilizer has been used the crop has been distinctly smaller and appreciably later.

For gooseberries a moderate application of manure, supplemented with a light dressing of commercial fertilizers, is recommended.

The manuring of garden and allotment crops, P. L. DE VILMORIN (*Jour. Roy. Agr. Soc. England*, 63 (1902), pp. 142-163).—A discussion of the principles involved in the use of commercial fertilizers, with the formulas recommended in France for peas, beans, potatoes, tomatoes, eggplants, cabbages, cauliflowers, radishes, lettuce, artichokes, spinach, melons, cucumbers, pumpkins, parsnips, turnips, salsify, onions, fruit trees, ornamental trees and shrubs, roses, and chrysanthemums.

Report on vegetables and plants grown at Chiswick in 1902 (*Jour. Roy. Hort. Soc. [London]*, 27 (1902), No. 2-3, pp. 633-665, figs. 5).—Cultural and descriptive notes on a number of varieties of tomatoes, perennial asters, phloxes, potatoes, and miscellaneous vegetables and flowering plants grown at Chiswick in 1902.

Asparagus; its culture, yield, and future, C. ALVARGONZÁLEZ (*El espárrago; su cultivo, su rendimiento, su porvenir*. Gijón, Spain: Mauro, 1902, pp. 24, figs. 3).—Popular directions for the culture of asparagus.

Ginseng culture, N. O. BOOTH (*New York State Sta. Rpt. 1901*, pp. 356-358).—Popular directions for the culture of ginseng.

Lettuce, E. S. BROWN (*Amer. Gard.*, 24 (1903), No. 430, pp. 183, 184).—An account of the culture of lettuce at the American Gardening trial grounds is given, with descriptions and cultural notes on 12 varieties, and notes on the growth of endive, cress, and mustard.

Onions, E. S. BROWN (*Amer. Gard.*, 24 (1903), No. 431, pp. 199, 200).—An account of the culture of onions in American Gardening trial grounds, with descriptions of 6 varieties.

The artificial crossing of Victoria and Princess Royal peas, N. L. CHEESTEN-SEN (*Deut. Landw. Presse*, 30 (1903), No. 25, p. 213).—The author desired to secure a pea which would ripen earlier than the Victoria, have shorter straw, and possess the productive qualities of the Princess Royal variety. These 2 varieties were therefore crossed, using each variety alternately as mother plant. In the second generation

hybrids 2 distinct varieties were secured which later proved permanent in character. One of these was very similar to the Victoria in height and appearance, but ripened about 14 days earlier. This variety was also more productive than the original Victoria. The second variety secured was a medium tall growing sort about 70 cm. high and unusually productive.

The tomato, J. J. WILLIS (*Gard. Chron.*, 3. ser., 33 (1903), No. 844, p. 132).—In order to understand the manurial requirements of the tomato, a study was made of the chemical composition of the fruit, vines, and roots. The amount of nitrogen, phosphoric acid, potash, and lime in a ton of these different parts of the tomato plant is shown in the following table:

Composition of tomatoes.

Description.	Nitrogen.	Phosphoric acid.	Potash.	Lime.
	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>
In fruit	3.2	1.0	5.4	2.0
In vines (green)	6.4	1.4	10.0	6.7
In roots	5.4	.2	7.6	12.0
In whole plant	5.0	.9	7.7	6.9
In half ton barnyard manure	5.5	4.0	6.0	8.0

When the amount of fertilizers contained in the whole plant is compared with that contained in a half ton of barnyard manure, it is seen that the manure contains $\frac{1}{2}$ lb. more nitrogen, a little over 3 lbs. more phosphoric acid, and 1 lb. of lime more than the tomatoes. On the other hand, it contains about $1\frac{1}{2}$ lbs. of potash less than the tomatoes. The author states that it is desirable to supplement barnyard manure with potash fertilizers for tomatoes. For late crops of tomatoes a smaller amount of nitrogen is required than for the early crop and a larger percentage of phosphoric acid and potash.

The following formulas are recommended for tomatoes: (1) One part nitrate of soda, 2 parts dried blood, 4 parts superphosphate or bone meal, and 3 parts kainit; (2) 1 part nitrate of potash, 2 parts guano or dried blood, and 2 parts superphosphate or bone meal. These manures may be applied as soon as the first fruits are set. They may be dissolved and applied at the rate of half an ounce in a gallon of water once a week, or the same quantity sprinkled over a square yard of soil.

The tomato, E. J. KYLE and E. C. GREEN (*Texas Sta. Bul.* 65, pp. 31, figs. 6).—A popular account of the culture of tomatoes in truck gardening, with a discussion of various methods of marketing, such as consigning to commission firms, selling at the track, selling on contract, and selling on the cooperative plan.

Variations in some introduced garden vegetables, H. C. IRISH (*Proc. Soc. Prom. Agr. Sci.* 1902, pp. 63, 64).—Some of the characteristics of Mikado pepper, Chinese Giant pepper, Triumph radish, and Dwarf Willow Leaf bean are briefly pointed out.

Orchard studies—II. The fruit plantation. Stone fruits, W. B. ALWOOD (*Virginia Sta. Bul.* 129, pp. 107-115).—The station farm is located on a high plateau at an elevation of about 2,200 ft. and is subject to rapid changes of temperature, therefore only medium results can be reported with stone fruits. Peaches have quite generally been a failure. The plum crop has sometimes been entirely killed by frosts but occasionally full crops are secured. A list is given of 21 varieties of cherries, 54 of peaches, nectarines, and apricots, and 101 of plums that have been grown at the station, with indications as to their adaptability for culture there.

Orchard studies—III. Notes on some of the more important varieties of apples, W. B. ALWOOD (*Virginia Sta. Bul.* 130, pp. 119-146, figs. 12).—The unfavorable conditions of soil and climate at the station for apple culture are noted and

descriptions given of 6 summer, 9 autumn, and 17 winter varieties that have been successfully grown at the station with only ordinary attention as to cultural details.

Apple shipments to the Orient, H. B. MILLER (*Oregon Bd. Hort. Rpt. 1901-2*, pp. 190-192).—An account of the shipment of several varieties of apples to China. The apples were packed in boxes and wrapped in paper. The losses with the different varieties were as follows: Ben Davis, 2 per cent; Tawoer, 10 per cent; Spitzenberg, 10 per cent; Shannon Pippin, 25 per cent; Jonathan, 50 per cent, and Red Russian, 75 per cent.

The varieties of fruit that can be profitably grown in Pennsylvania, G. HESTER (*Pennsylvania Dept. Agr. Bul. 106*, pp. 50, map 1).—The author sent letters of inquiry to 3,000 fruit growers throughout the State and received answers from more than 1,000 of these, representing every county and every fruit-growing section in the State. Based on these data, directions are given for the location and culture of apples, pears, peaches, plums, grapes, and cherries in the different sections of Pennsylvania. Tables are given showing the varieties of these fruits most suitable for each section in the State and many of the varieties are briefly described. Each county of the State is taken up and its suitability for fruit growing discussed, varieties adapted for culture in the county being noted.

Thinnage of peaches, E. J. KYLE (*Texas Truck Grower*, 1 (1903), No. 24, p. 1).—Summary of the advantages derived from thinning peaches, with details as to time and methods.

Sulphured dried fruit and its examination, W. FRESenius and L. GRÜNHUT (*Ztschr. Analyt. Chem.*, 42 (1903), No. 1, pp. 33-41).—The sulphuric acid found in samples of California apricots, peaches, and pears, Italian prunes, and other dried fruits of this sort is tabulated and commented upon.

Modern fruit culture; production, commerce, and utilization of fruits, E. DURAND (*La culture fruitière moderne; production, commerce et utilisation des fruits*. Paris: J. B. Baillière & Son, 1902, pp. 272, figs. 28).—A popular discussion of present-day methods in France.

Modifications in the forms of fruits; influence of the intermediate subject in top-grafting, P. PASSY (*Rev. Hort. [Paris]*, 75 (1903), No. 5, pp. 105-108, figs. 6).—A discussion is given, with illustrations, of the differences in the forms of pears obtained by top-grafting the Curé variety with Doyenné d'hiver and Crassane.

Modifications in the form of the pear and apple by dimorphism, P. PASSY (*Rev. Hort. [Paris]*, 75 (1903), No. 4, pp. 85-88, figs. 2).

Concerning root pruning, A. C. IDE (*Cultura*, 14 (1902), No. 171, pp. 424-426).—This brief paper, copied from the yearbook of the Netherland Pomological Society for 1902, records an experiment on severe root pruning of young apple and pear trees at the time of transplanting. The writer selected 1, 2, and 3 year old apple and 1, 2, and 3 year old pear trees. One-half of each lot were transplanted in the usual manner, while the others had their roots so severely pruned that only a stick was left. The trees of the first lot started off most vigorously in the spring, but before the end of June the closely pruned trees were larger than the others, and this lead was maintained throughout the season. When the trees were dug up it was found that the closely pruned ones had developed a much better root system than the others.—H. M. PIETERS.

Banana and plantain culture, T. KOSCHNY (*Tropenpflanzer*, 7 (1903), No. 3, pp. 112-124).—The botanical relationship of these fruits, their uses, and methods of culture are discussed.

Cacao culture in the Philippines, W. S. LYON (*Philippine Bureau Agr., Farmers' Bul. 2*, pp. 25).—Popular directions for the culture of cacao in the Philippines, including notes on climate, location, soil, planting, cultivation, pruning, harvesting, enemies and diseases, manuring, varieties, and the estimated cost and revenue derived from a cacao plantation.

Cacao; experiments in drying at Dominica (*Agr. News [Barbados]*, 1 (1902), No. 6, p. 85).—By the aid of a dryer maintained at the temperature of 110 to 120° F., cacao was successfully dried within 24 hours.

***Coffea stenophylla*, P. von Romburgh** (*Teysmannia*, 12 (1901), No. 12, pp. 605-610).—The difficulties surrounding the culture of Arabian coffee have led planters to turn to several means of relief. Hybrids between the Arabian and Liberia coffees have been tried with some success and the methods of grafting the Arabian on Liberia stock have been perfected. But the author thinks there is room for improvement, and to this end suggests *Coffea stenophylla*, by some considered as a variety of *C. arabica*. *C. stenophylla* has been grown at the Buitenzorg gardens and has fruited. It gives promise of being valuable, and further trials are under way.—H. M. PIETERS.

Silkworm food plants—cultivation and propagation, G. W. OLIVER (*U. S. Dept. Agr., Bureau of Plant Industry Bul. 34*, pp. 20, pls. 13).—Methods of propagating mulberries from seed and by cuttings, root grafts, shield budding, and by scion or sprig budding, are described and illustrated, and suggestions made regarding the soil for mulberries, planting, and pruning. The subject is treated from the standpoint of mulberries as food for silkworms. Osage orange leaves form a suitable food for silkworms when the worms are given an opportunity to select the leaves themselves, but when young and immature leaves are fed they have a tendency to sicken the worms. "Ignorance of this fact renders the use of the osage orange dangerous."

Fourth report on experiment in pinching raspberry shoots, F. CRANEFIELD (*Wisconsin Sta. Rpt. 1902*, pp. 259-267, figs. 3).—The author has investigated the value of the practice of pinching the tips of growing raspberry shoots to induce branching and fruitfulness. The earlier results obtained in this work have been previously noted (*E. S. R.*, 13, p. 953). The following table shows the yields obtained in 1902 and the average yields for 4 years with the Gregg and Cuthbert varieties. In each experiment there were 36 plants.

Yield of raspberries on pinched and nonpinched shoots.

Treatment.	Gregg.		Cuthbert.	
	Yield, 1902.	Average of 4 seasons.	Yield, 1902.	Average of 4 seasons.
	Ounces.	Ounces.	Ounces.	Ounces.
Shoots not pinched	416.8	954.7	397.4	970.2
Shoots pinched at 12 in.	407.5	795.1	347.7	830.5
Shoots pinched at 12 in., laterals at 12 in.	1,000.9	1,118.7	408.7	857.7
Shoots not pinched	402.5	814.1	527.0	996.4
Shoots pinched at 18 in.	560.6	1,150.8	419.0	864.7
Shoots pinched at 18 in., laterals at 12 in.	491.8	1,046.6	415.8	908.3
Shoots not pinched	452.5	952.8	841.3	773.4
Shoots pinched at 24 in.	502.5	1,261.4	750.2	992.9
Shoots pinched at 24 in., laterals at 12 in.	502.8	1,182.4	658.4	773.7

This table shows that the largest average yield of the Gregg variety was obtained from the row pinched once at 24 in. Averaging the results of 4 years, for the 2 rows pinched 12 in. there was a yield of 956.9 oz., for the 2 rows pinched 18 in. a yield of 982.4 oz., and for the 2 rows pinched 24 in. a yield of 1,221.9 oz. For the 3 rows not pinched the average yield for 4 years was 907.2 oz. These results indicate that the yield of the Gregg variety has been increased by pinching. With the Cuthbert variety the 3 rows not pinched yielded an average of 913.3 oz.; the 2 rows pinched at 12 in. 844.1 oz.; the 2 rows pinched at 18 in. 886.5 oz.; and the 2 rows pinched at 24 in. 883.3 oz. Pinching with this variety appears to have decreased the yield.

An account was kept of the number of shoots and suckers produced on plants differently treated. The data presented indicate that pinching increased the production of shoots in the Gregg variety and decreased the production of suckers in the Cuthbert variety. A table is given showing the effect of pinching on the size of the ber-

ries for the 2 years 1901 and 1902. It indicates that pinching slightly increased the size of the berries with the Gregg variety while with the Cuthbert variety the size was slightly decreased. As to the effect of pinching on the form of the vines, rows pinched but once spread fully as much as those not pinched at all. Rows pinched twice were a trifle more compact.

Experiments in orchard, vineyard, and cellar, H. SCHELLENBERG (*Jahresber. Vers. Stat. u. Schule, Wädenswil, 1899-1902, pp. 54-64*).—This report includes a test of varieties of pears, fertilizer experiment with grapes, test of American grape stocks, experiments in wine making and handling, tests of the durability of posts differently treated, etc. Of 84 posts impregnated with copper sulphate but 16 had rotted 10 years later. In another case where 97 posts were treated in a like manner but 3 had rotted at the end of 10 years. Similar results have been obtained when the posts were treated with creosote. All of the posts treated with cyanid were still in use at the end of 10 years. Training vines low and pinching off the bearing shoots 2 leaves beyond the last bunch of fruit early in the season has given better results than training high, or than training high or low later in the season and leaving on 4 leaves beyond the last bunch of grapes.

In a test of the relative merits of Steinberger and Rauenthaler pure yeasts for the fermentation of white wine, better results were obtained with the Steinberger yeast. In an experiment with red wine, fermentation was allowed to develop naturally in one portion, Assmannshäuser pure yeast was added to another portion, and Winterthurer pure yeast to another portion. Fermentation was much the most rapid when the Assmannshäuser pure yeast was used. The wine to which Winterthurer pure yeast was added stood next in rapidity of fermentation. There was also much more coloring matter in the Assmannshäuser wine than in the other 2 lots, and the taste was much more agreeable.

Pruning green grapevines, J. M. GUILLON (*Rev. Vit., 19 (1903), No. 484, pp. 364-367*).—The relative merits of disbudding grapes when the young branches had attained a length of 10 cm., pinching off the shoots 2 leaves beyond the fruit bunches, pinching the extremities of the branches just before flowering, and pruning off all the branches that exceed the height of the trellis, were compared. A number of vines were left unpruned for comparison.

The untreated vines yielded at the rate of 66 kg. per 100 vines and the disbudded vines at about the same rate. Pinching the vines 2 leaves beyond the fruit as soon as the leaves attained the size of a silver dollar resulted in the development of a number of the secondary branches which had to be pruned when they had reached about the same stage of development. The more vigorous growth of vines thus developed was more difficult to manage for the control of insect pests and fungus diseases. The total weight of the harvest, however, was 92 kg. of mature grapes and 25 kg. of immature grapes per 100 vines. Pinching in this case seemed to favor the fertilization of the flowers but resulted in a rather too energetic growth. Pinching the vines at the extremities just before flowering seemed to favor fructification, since 100 vines yielded 98 kg. of good, mature grapes as compared with 66 kg. in the control plat.

Pruning the vines when they had exceeded a certain height was done at 2 different times, about July 4 and August 22. The yield obtained from vines pruned on the first day was 74 kg. per 100 vines and at the latter day 82 kg. per 100 vines.

The results here given are for 1 year only but they indicate an advantage in pruning green grapevines, more particularly pinching of the extremities of the shoots just before flowering. The experiments are to be continued.

Experiments in manuring grapes, E. MARRE (*Prog. Agr. et Vit. (Éd. L'Est), 24 (1903), No. 13, pp. 388-396*).—An account of some cooperative experiments in fertilizing grapes to determine the effect on the quality of the wine. The results obtained were not uniform.

Budding the pecan, G. W. OLIVER (*U. S. Dept. Agr., Bureau of Plant Industry Bul. 30, pp. 18, pls. 8*).—Methods of successfully budding and transplanting budded pecan trees are given, together with a number of drawings illustrating the various phases of the subject. The principal trouble arising from budding pecans seems to be due to the selection of immature buds. The author prefers for planting nuts obtained from the northern borders of the pecan belt since these are likely to be more hardy than those grown farther south. Over winter they should be layered in boxes filled in alternate layers with a mixture of sand and ashes. Rows in spring are planted east and west so that the trees may be budded on the north side. In planting trenches are made about 3 ft. apart and 5 in. deep. The bottoms of these are covered about 2 in. deep with a mixture of equal parts leaf mold and sand. The nuts are spaced 5 in. apart and the soil raked over them. Above the rows a half-inch mulch of half rotted leaves, cut cornstalks, or other materials is placed to prevent the soil from baking. The buds selected for propagation should be those formed during the preceding season. These dormant buds are easily removed from the bud stick and can be handled without injury. After union and the cutting back of the stocks these buds make a much stronger growth during the remainder of the season than would buds of the current season's growth. The best buds are obtained from near the base of the shoots which grew from axillary buds the preceding season. As soon as the bud stick is cut from the tree the current season's growth is cut off and discarded and the 1-year-old bud sticks wrapped in dampened newspapers. In this manner they can be kept for several days if necessary.

In budding 2 transverse cuts, a few inches above the ground line, are made about an inch apart. These are connected by a longitudinal cut through the center. The bark on either side of this longitudinal cut is raised to admit the bud. The bud is cut exactly the same length, about 1 in. long and $\frac{3}{4}$ in. wide, with the bud in the center. Considerable care is necessary in raising the patch from the bud stick to prevent breaking the bark and otherwise injuring it. The outer bark of the bud patch is shaved off a little so that the edges will make a perfect fit under the bark of the stock. After the bud has been placed securely in position the bark of the stock is bound firmly over it and held in place with raffia. A little soft grafting wax is smeared across the top of the cut to prevent the admission of water, and the whole patch except the bud wrapped with a narrow strip of waxed cloth. The wrapping is begun at the bottom and each wrap half covered by the succeeding one. As a protection against the sun a strip of paper about 8 in. long and 6 in. wide is tied about an inch above the bud. The paper extends downward and covers the bud but is left open at the bottom. After the sixth day the paper covering is removed and after the tenth day the wax cloth taken off. By the end of the fifteenth day the buds will have united sufficiently to permit of the removal of the raffia.

This method of budding is stated to make a very satisfactory union. With carefully selected buds from 1-year-old wood and vigorous growing seedling stocks, practically every section of the bark will unite.

When the seedling stocks are small a triangular bud patch may be used. Great care must be taken that the patch exactly fit the patch of bark removed from the stock. One apex of the triangle should point upward. A small quantity of soft grafting wax should be smeared over the cut before it is tied with raffia. This method of budding is especially useful with small buds; with the large buds a larger section of bark is needed.

Buds should be encouraged to start promptly into growth. This is facilitated by removing the top of the seedling, leaving only 1 or 2 healthy leaves at the base of the present season's growth. The buds in the axils of the leaves which start out within a few days should be promptly removed. Within a month the scion bud will have developed several full sized leaves. If the buds are inserted before the end of June there will be abundant time for the development of a good sized shoot. The

practice of tying the scion to the stock is recommended. At the beginning of the second season all of the stock above the scion should be smoothly cut off and covered with melted grafting wax to prevent decay.

Transplanting with budded stock should not be attempted until the third year on account of the danger involved in interfering with the growth of the tap root of the tree. If budding is practiced when the seedling is 2 years old the tree should remain unmoved until the end of the growing season the following year. In removing the tree the retention of the roots for at least 2½ ft. below the surface of the soil is desirable. As soon as the roots are removed from the soil they should be dipped in liquid mud, after which they should be promptly wrapped in damp sacking, moss, or other like material, and kept in a moist condition until planting time. Before planting they should be again plunged in liquid mud. Excessive trimming of either the branches or the roots of the tree at transplanting time should be avoided. At least one healthy undisturbed shoot of the previous season must be left on the plant untouched "because the large plump axillary buds near the tip of the shoot will come into leaf with greater certainty and more quickly than will older buds on cut-back growths."

Experiments with manures for chrysanthemums, G. TRUFFAUT (*Jour. Soc. Nat. Hort. France*, 4. ser., 3 (1902), Dec., pp. 822-832, figs. 5; *abs. in Gard. Chron.*, 3. ser., 33 (1903), No. 848, p. 200; *Amer. Florist*, 20 (1903), No. 775, pp. 418-420).—An account is given of the results of pot experiments in the culture of chrysanthemums in 10 different localities in France with various combinations of fertilizers. In every instance the soil used was analyzed before the experiment began. The results of these analyses, together with the growth of the plants on the soils when differently fertilized, are reported in detail.

The variety *Madame Gustav Henry* was generally grown. The plants were trained, some to 3 branches, some to 6 branches, and some were not disbudded at all. Four plants were used in each instance as controls, 4 received a complete fertilizer, 4 a double quantity of complete fertilizer, 4 a complete fertilizer without nitrogen, 4 a complete fertilizer without potash, and 4 a complete fertilizer without phosphoric acid. At the time of potting the various fertilizers were thoroughly mixed with the soil. They consisted of 25 per cent fish guano, 16 per cent dried blood, 24 per cent sulphate of potash, and 35 per cent double superphosphate. This mixture analyzed 45 per cent nitrogen, 11 to 12 per cent potash, and 15 to 16 per cent phosphoric acid. Later in the season a solution of fertilizer was used for watering the plants made up of 54 per cent phosphate of potash and 46 per cent nitrate of soda, analyzing 6.9 per cent nitrogen, 14.04 per cent potash, and 20.52 per cent phosphoric acid. The fertilizers mixed with the soil were used in the proportion of 900 gm. to 100 kg. of soil. In the solutions 2 gm. per liter was used.

In the fall of 1902 each of the cultivators presented at a meeting of the horticultural society a specimen plant representing the average of the results obtained in each experiment. One of the experimenters had employed white sterile sand for the experiment in growing the plants, the object being to study the specific effect of each of the essential fertilizer elements. The object sought by remaining experimenters was to study the influence of the complete and supplementary fertilizers in soils of known composition and also the influence of climate on the action of fertilizers and the culture of the same variety.

The best results secured when sterile white sand was used were with a complete fertilizer. Plants without potash stood next, then those without nitrogen, while the poorest result of all was obtained when phosphoric acid was omitted. The plants without phosphoric acid were chlorotic, and had weak stems and small flowers. When potash was omitted from the complete fertilizer the plants had a weak habit, the leaves were large, thick, and green, but soft and easily fell from the plant. The stems were large and hollow and the flowers large but of bad form. When nitrogen

was omitted from the complete fertilizer the plants were yellowish, the leaves thick and small, the stems weak, and the flowers few in number, small, and hollow at the center.

The results secured with good potting soils in the other experiments on the whole indicate that a potting soil for chrysanthemums should contain $2\frac{1}{2}$ gm. of nitrogen, $1\frac{1}{2}$ gm. of phosphoric acid, and $1\frac{1}{2}$ gm. of potash per kilogram. For the out-door culture of chrysanthemums it is suggested that the chrysanthemum soil contain at least $1\frac{1}{2}$ gm. of nitrogen, 1 gm. of potash, and 1 gm. of phosphoric acid per kilogram. In practice it is advised that a soil for chrysanthemums be made up of 2 parts of good sandy loam and 1 part of leaf mold. These should be thoroughly mixed and a sample sent to a chemist for analysis. With a knowledge of the elements that a chrysanthemum soil should contain the fertilizers to be added can be easily determined. An excess of nitrogen in the soil favors the development of diseases. Should this element be lacking it may be added in the form of dried blood, horn, or guano. Potash is best added in the form of sulphate of potash and phosphoric acid in the form of superphosphate of bone or of precipitated phosphate. With the chrysanthemums grown in pots it is extremely desirable that soluble manures be added, beginning about August 15.

The effect of climate on the different plants is shown quite clearly. There was a difference of about 3 weeks in the development of the plants between Lille and Avignon. The fertilizers also appeared to be more effective in the north of France than in the south.

Conference on roses at the Holland House (*Jour. Roy. Hort. Soc. [London]*, 27 (1902), No. 2-3, pp. 445-563, figs. 34).—At this conference, which was held in London, June 24 and 25, 1902, the following papers were presented: A Synoptic Table of the Sections of the Genus *Rosa* According to the Classification of M. Crépín, by J. Gérôme; Rose Forcing in America, by Anne Dorrance; Some Wild Asiatic Roses, by M. L. de Vilmorin; New Hybrids to Aim at, by Viviani-Morel; On Different Ways of Striking Roses, by Viviani-Morel; Sensitiveness of Cultivated Roses to Changes of Weather, by E. Mawley; The Hybrid Tea, by J. H. Pemberton; Exhibition Roses, by G. Paul, etc.

Mendel's principles applied to orchid hybrids, C. C. Hurst (*Jour. Roy. Hort. Soc. [London]*, 27 (1902), No. 2-3, pp. 614-624, figs. 3).—The hybrid orchid *Paphiopedilum* \times *Leeanum*, obtained by crossing the 2 species *Paphiopedilum spicerianum* and *P. insigne*, was crossed with *P. boxallii* with the idea of testing Mendel's theory as to the purity of the single character determinants in the germ cells of hybrids. During the past 4 years 49 hybrids thus obtained have flowered. There was an extremely wide variation in the form and color of the different hybrids, no two of the flowers obtained being alike, and the extreme forms were very distinct. If the species *P. spicerianum* be represented by S, *P. insigne* by I, *Paphiopedilum* \times *Leeanum* by SI, *Paphiopedilum boxallii* by B, progeny of the crosses of the two latter, according to Mendel's theory, must come out for any single character, either BS or BI, but not BSI. This is exactly what happened. The dorsal sepal of the hybrid was selected as the single character for investigation and examined with respect to (1) ground color, (2) markings on ground color, and (3) median band, the average for these 3 factors being 76 BS and 71 BI, which is a fair approximation to the equality which Mendel's theory presumes. It is therefore believed that as far as these experiments go "they confirm Mendel's theory of the purity of the determinants in the germ cells of hybrids . . . and for all practical purposes Mendel's principles may be safely accepted as a working formula for the hybridist in general, and the orchid hybridist in particular." Illustrations are given of 32 of the hybrids which happened to flower together.

The book of the wild garden, S. W. FITZHERBERT (*London and New York: John Lane, 1903*, pp. 96, pls. 9).—Cultural and descriptive notes on hardy plants for out-

door garden culture. This book is the thirteenth of the series of Handbooks of Practical Gardening, edited by H. Roberts.

A new design of greenhouse (*Amer. Agr.*, 71 (1903), No. 14, p. 391, figs. 2).—One of the peculiarities of this greenhouse is the curved eave line. There is no eave plate and no gutter. Illustrations are given of the interior and exterior of the house, which was built at Briarcliff, New York, in 1901.

Horticulture in Egypt, L. SAUNDERS (*Jour. Roy. Hort. Soc. [London]*, 27 (1902), No. 2-3, pp. 629-632).—An account of recent development along horticultural lines in Egypt.

FORESTRY.

The principal species of wood, their characteristic properties, C. H. SNOW (*New York: John Wiley & Sons, 1903*, pp. XVI + 203, pls. 39, figs. 20).—This book, which, as the author says, is not designed primarily for foresters, botanists, or engineers, but for all the users of wood who desire knowledge regarding their distinguishing properties, gives in untechnical terms the principal features which characterize the economically important species of wood. The necessary terms used are first defined, after which the structure, methods of growth, and appearance in different sections of woods are described. The differences in wood that distinguish the greater subdivisions are pointed out, after which the species are described under appropriate groupings. In many cases the species are grouped under their generic names, or a number of nearly related forms are brought together. The distribution, structural and physical properties, commercial features, and botanical characteristics are first described for the genera, after which the leading species are considered in detail. Of the more than 120 species of timber described, most of them are indigenous to the United States, although a few of the more important exotic species are included. The illustrations, which are a highly commendable feature of the work, show the general aspect of the tree and a large section of the trunk, the grain characteristics of the wood, and in many instances the leaf and fruit in detail. Of the 155 figures that go to make up the plates nearly all are original, and reproduction is well done. The publishers have presented the work in an attractive form, and this book will doubtless be found useful for students as supplementing the technical works on botany and forestry, as well as giving desired specific information regarding our more important timber trees.

Applied ecology, B. E. FERNOW (*Science, n. ser.*, 17 (1903), No. 433, pp. 605-607).—After giving the definition of ecology the author proceeds to discuss it from its silvicultural relations. This is done in the hope of stimulating observations which will aid in solving some of the perplexing problems of the practical forester. According to the author, the silvicultural factors may be divided into 2 classes, those which are stable and the variable ones. The stable factors are soil and general or local climate, while the unstable ones are seasonal variations, plant and animal associates, and light. These different factors are discussed at some length and the hope expressed that others will take up and pursue the subject, particularly that relative to light and shade.

A study of the redwood, R. T. FISHER (*U. S. Dept. Agr., Bureau of Forestry Bul.* 38, pp. 1-28, pls. 9, figs. 2).—This study is made more with reference to the young, second-growth redwood than to the mature trees. The author claims that redwood reproduces itself abundantly by sprouts on cut-over land and occasionally by seed; that in 30 years in a fair soil and a dense stand it will produce trees 16 in. in diameter and 80 ft. high, yielding 2,000 ft. B. M. per acre. On account of this rapid reproduction, after careful lumbering it will pay to hold cut-over redwood lands for future crops.

The redwood described is *Sequoia sempervirens*. Its distribution through California and into Oregon is indicated, and the climatic conditions required by the tree are

shown. Two types of redwood forest are described, the redwood slope and redwood flats. The characteristics of the timber, the quality of its wood, reproduction, associated species, and enemies are described. The yield of redwood is shown to range from 20,000 or 30,000 to 125,000 to 150,000 ft. B. M. per acre, depending on the locality. The amount of timber gotten out, however, is a small proportion of the actual stand, as at least one-fourth is destroyed in the ordinary processes of lumbering. A history is given of the lumbering of the redwood. Its extent and present operations and the results of studies of cut-over lands are shown, in which the rate of growth and merchantable yield are given. The conservative management of redwood forests, as indicated by the report of a company operating in that region, shows that the redwood can be readily handled as a permanent investment if sufficient seed trees be left and the protection given against fire and other injuries.

Report of the superintendent of State forests, W. F. Fox (*New York State Forest, Fish, and Game Com. Rpt. 1902, pp. 11-67, pls. 20, maps 2*).—A detailed report is given of the forestry work conducted under the direction of the commission during the year 1902. Special mention is made of the subject of fire protection. During the year covered by the report it is stated that while 21,356 acres were burned over in New York, more than three-fourths of this was waste land on which there was no merchantable timber. Attention is again called to the restriction limiting the work of the forester to reforestation through planting, etc., no provision being made for improvement cuttings. Forest nurseries have been established for the production of seedlings for future plantings, and a detailed report is given of the planting operations conducted during the year. The total area in the Adirondack and Catskill forest reserves is said to be 1,408,181 acres, to which there were added during 1902, by purchase and tax sales, 28,505 acres, making the total State forest reserves 1,436,686 acres. The private preserves within the State, a list of which is given, contain 791,208 acres of forest land. An attempt was made to collect statistics regarding the timber output of the State, and it is said that the total output of the Adirondack and Catskill forests amounted to 659,382,520 ft. B. M., with 38,148,250 shingles and 56,396,000 laths additional.

A report on dead and diseased trees on Long Island, A. KNECHTEL (*New York State Forest, Fish, and Game Com. Rpt. 1902, pp. 67-76, pl. 2*).—At the direction of the forester, the author visited Flushing and Port Jefferson to ascertain the cause of the death of numerous shade trees in those towns. The shade trees of Flushing are noted for their beauty, size, and variety, and as a large number of trees died during the years 1901 and 1902 the investigation was undertaken at the request of the citizens at that place. An examination of many of the trees showed them to bear evidence of insect attacks, particularly that of the white-marked tussock moth. In addition many trees were found in which the evidence seemed strong that their death was due to the escaping of gas. Suggestions are given for the care of street trees and recommendations made for the prevention of future losses. At Port Jefferson specimens of pitch pine occurring in a park were found dead and dying, and an examination showed that the trees were badly attacked by fungi, which had gained entrance through improper pruning. Others had died from crowding and too much shade, and the thinning of the trees was recommended as a protective measure.

Gathering spruce seed, C. R. PERTIS (*New York State Forest, Fish, and Game Com. Rpt. 1902, pp. 76-87, pls. 3*).—In order to supply seed of the native red spruce for the State nurseries the author undertook gathering the seed in considerable quantity. The methods adopted are described in detail, and it was found that the seed could be collected in considerable quantity at a saving of about 50 per cent of the market price.

Report of the Maine Forest Commissioner, 1902, E. E. RING (*Maine State Forest Comr. Rpt. 1902, pp. 1-61, pls. 12*).—This report contains an account of investigations relating to the stand of merchantable spruce timber within the State, a sum-

mary of which has already been given (E. S. R., 14, p. 872). A discussion is given of some of the enemies of the forest in which the destruction caused by fire, winds, wasteful cutting, etc., is described. A brief résumé is given of forestry principles and practices of the United States and a number of foreign countries, together with the act of the legislature creating a bureau of forestry in Maine. Various conclusions are drawn from the investigations of the author, and recommendations regarding future lines of work are made.

A study of the Maine spruce, R. S. HOSMER (*Maine State Forest Comr. Rpt. 1902*, pp. 65-108, pls. 13, map 1).—This work was carried on in connection with the Bureau of Forestry of this Department, and a report is given of the spruce timber as observed from a survey made in one of the counties of that State. The situation, topography, and soils of the tract surveyed are described, and the forest is considered under different types of swamp, flats, slopes, etc. The method of reproduction of the spruce is described at some length and estimates made regarding the present stand, rate of growth, and future yield. Associated with the spruce are various hard woods, and suggestions are given for the lumbering of these as well as of the spruce. A list is appended of the trees and shrubs observed associated in the spruce forests. The conclusions of the author relating to the handling of these spruce forests are summarized and the author believes that practical forestry may be advantageously introduced to supply continually the demands of pulp and sawmills. For this purpose working plans will be needed for different regions. In conservative lumbering the author believes that cuttings should be limited to trees of considerable diameter. This will leave the forest in better condition after lumbering than when a smaller limit is used, but the diameter limit will be found subject to modification as a result of the character of the forests and the requirements of the owners. The hard woods should be lumbered wherever possible, both on account of their present value and the improvement to the forest caused by their removal.

Distribution of plants in forest regions, W. M. MUNSON (*Maine State Forest Comr. Rpt. 1902*, pp. 111-124, pls. 4).—Some of the methods of seed distribution are described, and the distribution as affected by modifications of fruits and seeds is shown. The effect of winds, water, birds, and other animals as agents in seed distribution is indicated, and the limitations of time and environment in the production of forest species are shown. It is said that a natural succession of forests is due to changed natural conditions, and the succession may be rapid as when an area is swept by fire, or it may be the result of gradual encroachment of more dominant species.

Management of pulp wood forests, A. CARY (*Maine State Forest Comr. Rpt. 1902*, pp. 125-144, pls. 12).—An account is given of the management of the pulp wood forests by the Berlin Mills Company, and notes are given on some of the insect and fungus pests which threaten the destruction of the spruce timber. The principal injury is due to the bark beetle (*Dendroctonus piceaperda*). The habits of the insect are described and practical remedies suggested for preventing its ravages. Notes are also given on other insects as well as on the fungus *Polyporus volvatius*, which is frequently found growing out of spruce bark.

The regeneration of woods from seed naturally or artificially sown, A. C. FORBES (*Trans. English Arbor. Soc.*, 5 (1902-3), pt. 2, pp. 239-270, pls. 2).—The author discusses the natural regeneration of forests and their formation from seed sown either naturally or artificially, as distinguished from plantations made from nursery-grown trees. The comparative advantages of sowing and planting are contrasted and the species adapted to sowing are indicated. Among the conditions necessary for successful natural regeneration of deciduous species the author claims that there should be present sufficient seed-bearing trees, the surface soil should be clean and porous, with an absence of large quantities of raw humus, the seed should be covered by the soil, the seedlings should be protected from injury, and there should

be a timely removal of the old crop of seed-bearing trees. The influence of each of these factors on forest production is discussed at considerable length. The treatment required by the regenerated areas is described, and typical examples of natural regeneration of oak, ash, and beech are cited. The regeneration of Scotch fir, raising plantations from seed, recurrence of seed years, means for collecting seed, and cost of sowing plantations are all discussed.

The natural regeneration of oak and beech woods, L. S. WOOD (*Trans. English Arbor. Soc.*, 5 (1902-3), pt. 2, pp. 278-290).—The relative merits of the selection and crop rotation systems applied to oak and beech woods in England are discussed.

The management of public and private parks, J. WILSON (*Trans. English Arbor. Soc.*, 5 (1902-3), pt. 2, pp. 271-277).—A discussion is given of the principles of planting and managing public and private parks.

Sawmills and wood-working machinery for estates, J. PRICE (*Trans. English Arbor. Soc.*, 5 (1902-3), pt. 2, pp. 291-306).—A discussion is given of the general subject of the establishment of mills and motive power, and descriptions are given of different kinds of saws and other wood-working machinery.

Reclaiming and planting bog land, T. CONWAY (*Trans. English Arbor. Soc.*, 5 (1902-3), pt. 2, pp. 307-315).—A description is given of various types of bog lands, and suggestions are given for their draining and planting, together with a list of the most suitable varieties of trees to plant. In planting bogs it is considered of advantage to prepare the soil while draining by composting as much as possible upon it the leaves, weeds, grass, and other material, as well as the addition of clay and lime, the latter to reduce the acidity of the soil. Where peat is present this should be burned, or if not burned the soil should be fallowed for at least 2 years. In planting, the most suitable trees for preliminary planting are said to be willows, Scotch pine, and spruces. The best time for planting bogs is in the early spring. Trees planted in the autumn in such wet soils generally perish. When the total area is prepared for planting, the trees may be selected from the list given, which includes alders, birches, Scotch pine, willows, poplars, spruces, and larch.

Revenue from the forest of Compiègne for 1900 (*Trans. English Arbor. Soc.*, 5 (1902-3), pt. 2, p. 229).—A tabular report is given showing the annual receipts and expenditures of the forest of Compiègne, in which the gross revenue amounted to \$189,218 and the total expenditures to \$31,453, leaving a net revenue of \$157,765 for the forest of 36,072 acres, or about \$4.50 per acre.

Trees on the farm, H. PYE (*Jour. Dept. Agr. Victoria*, 1 (1902), No. 9, pp. 847-852).—Attention is called to the desirability of tree planting, both as wind-breaks and for timber. The methods of planting and cultivation are described and lists given of trees which by their growth have shown that they are adapted to the conditions in the region for which the report is prepared.

SEEDS—WEEDS.

The acquisition of the germinative faculty in ripening seed, P. MAZÉ (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 24, pp. 1130-1132).—The author states that many experiments have been conducted to ascertain the time at which ripening grains attain their ability to germinate, the results obtained being more or less contradictory. He gives the results of his experiments with peas and maize, which were taken from the pod or ear at the time the seed was in the milk and placed immediately one by one in test tubes furnished with 2 plugs of cotton, one of which served to support the seed at the surface of the distilled water and the other intercepted the entrance of micro-organisms. Under these conditions the seed were kept for a considerable time at a temperature of 30° C. The maize finally gave normal plants which developed vigorously, while the seedlings of the peas were dis-

torted and in many cases the shoot was unable to break through the seed coats. In other cases the peas failed entirely to germinate. If the seed was dried in contact with the air or over concentrated sulphuric acid it was found that they would germinate more promptly and the seedlings be more nearly normal. The experiments with maize are described with considerable detail. Two rows of grain were detached from the ear, the first consisting of 20 grains placed to germinate immediately, while the second was dried for 48 hours over concentrated sulphuric acid, after which they were placed to germinate. The first lot germinated 20 seed in 30 days, while the second lot, which consisted of 19 seed, all germinated in 2 days.

In the second experiment with maize 3 lots of seed were removed from the ear while the grains were still in the milk stage. The first lot, consisting of 20 grains, was placed to germinate immediately. The second was exposed for 8 days in the laboratory, losing in this time a considerable portion of their water. The third lot was dried for 8 days over a weak sulphuric acid, after which it was placed to germinate. Of the first lot of seed but 2 germinated in 34 days, of the second lot 20 seed germinated in 14 days, while of the third, which consisted of 15 grains, all germinated in 3 days.

The influence of formaldehyde on the germination of oats, F. CRANFIELD (*Wisconsin Sta. Rpt. 1902, pp. 268-272*).—In the previous report of the station an account was given of the influence of formaldehyde on the germination of oats. In the present report further studies are given showing the influence of this fungicide on the viability of seed, in which stronger solutions were used and varying periods of time employed. It was found that soaking the seed in a solution of $2\frac{1}{2}$ parts of formaldehyde and 1,000 parts of water injured the seed oats from 6.4 to 17.4 per cent. Where stronger solutions were used the injury was increased in direct proportion. These tests were conducted under ordinary field conditions. In spite of the injury, the successful use of this fungicide for the prevention of oat smut, the author believes, warrants its continued use.

The effect of depth of planting on the germination of clover seed, F. CRANFIELD (*Wisconsin Sta. Rpt. 1902, pp. 273-279, figs. 2*).—The results of a number of trials in planting clover seed at different depths are given, the germination of the seed being noted at the end of 5, 10, and 20 day periods. The different lots of seed were planted to depths of $\frac{1}{8}$ in., $\frac{1}{4}$ in., $\frac{1}{2}$ in., $\frac{3}{4}$ in., 1 in., and 2 in. The experiments described involved the planting of about 45,000 seed, and the results obtained show that planting between $\frac{1}{8}$ and $\frac{3}{4}$ in. was the most favorable for rapid germination and produced the highest percentage of germination. When the seed were covered to a depth of 1 in. less than half germinated and when covered with 2 in. of compacted soil less than $\frac{1}{2}$ germinated.

The effect of sunlight upon the germinative power of seed, E. LAURENT (*Compt. Rend. Acad. Sci. Paris, 135 (1902), No. 26, pp. 1295-1298*).—On account of the injurious action that sunlight is known to exert upon bacteria, yeasts, spores of certain fungi, etc., the author conducted experiments to ascertain its effect upon the germinative ability of certain seeds. Seeds of wheat, rye, black and white mustard, cress, clover, dandelion, *Hieracium* spp., sow thistle, and groundsel were placed in tubes in series and exposed to the direct sunlight during a period of prolonged and intense sunshine. They were afterwards placed to germinate, and it was shown that the sunlight had exerted a detrimental effect upon them which in some cases entirely destroyed the embryos of the seed. In general, the larger seeds, such as rye, wheat, and those having white seed coats, as the white mustard, were less injured by the solar radiation than the small seed or those provided with dark-colored seed coats.

Experiments on the germination of seed preserved in a vacuum, E. LAURENT (*Compt. Rend. Acad. Sci. Paris, 135 (1902), No. 24, pp. 1091-1094*).—In 1894 the author placed the seeds of a large number of field and garden plants of the crops of 1892, 1893, and 1894 in test tubes, and so arranged them as to permit of the liberation

of carbon dioxid given off by the seed. These were examined for their germination after 2½ years, 5 years, and 7 years 4 months. The germinations secured in the different trials are reported upon. Those tested after the 5 years' interval showed that the following seed germinated well in the vacuum: Spinach, colza, cabbage, turnips, white and black mustard, cress, lupine, clover, beans, corn salad, and squash, while wheat, rye, barley, oats, maize, buckwheat, spurry, and poppy were decidedly injured by the treatment. Seeds of garlic, cumin, and chervil were killed. Similar results were obtained in the test conducted 7 years and 4 months after sealing up the seed. In general the results show that oil-bearing seed are better preserved in a vacuum than in contact with the air. Among the starchy seeds the ones which best withstood the prolonged deprivation of air were spinach, corn salad, clover, lupine, and beans, while wheat, rye, barley, oats, maize, and buckwheat were rapidly destroyed by such treatment. The author attributes the depreciation of oil-bearing seed to the rapid alteration of the fatty bodies in the presence of oxygen.

Red clover seed and its impurities, D. FINLAYSON (*Aynsme Agr. Sta., Grange-over-Strids, Cent. Seed-Testing Lab. Farmers' Bul. 1, pp. 8, pl. 1*).—Attention is drawn to some of the impurities found in red clover seed and directions given for sampling and for determining the purity and germination of clover seed. The author distinguishes between the red clover, which he calls *Trifolium pratense*, and the perennial red clover, to which the name *Trifolium pratense perenne* is given.

Notes on weeds, T. W. KIRK (*New Zealand Dept. Agr. Rpt. 1902, pp. 373-380, figs. 3*).—Notes are given on a number of noxious weeds and suggestions for their eradication. Particular attention is given to the ragweed (*Senecio jacobaeus*) and the ox tongue (*Picris echinoides*).

DISEASES OF PLANTS.

Plant depredations and plant culture, F. W. RANE (*Proc. Soc. Prom. Agr. Sci. 1902, pp. 160-164*).—The author attempts to emphasize the relation which exists between host plants and their parasites and points out a condition which influences to a greater or less extent their relationship. He argues for the better care of the host plant, neglect and improper handling being accompanied by weakened plants which are more subject to insect and fungus attack.

The æcidium as a device to restore vigor to the fungus, J. C. ARTHUR (*Proc. Soc. Prom. Agr. Sci. 1902, pp. 65-69*).—The author discusses the wintering forms of a number of rust fungi and the possible effect of their habit on the vigor of the parasite. So far as known *Puccinia rubigo-vera* produces only uredospores in North America, and on this account it is believed that this rust is less destructive than the black rust or *P. graminis*. A second illustration studied was that of *P. poarum*. This rust forms only uredospores in North America and is widely distributed, but produces so little effect upon its host as to be almost always overlooked. In Europe it produces 3 forms of spores, but some of the alternate hosts are wanting in this country. The author discusses the relation of *P. graminis* to wheat and barberry, and believes that if all the barberry plants could be totally destroyed the stem rust would ultimately become much less harmful than at present.

A contribution to the knowledge of rust fungi, E. JACKY (*Centbl. Bakt. u. Par., 2. Abt., 9 (1902), Nos. 21, pp. 796-805; 22-23, pp. 841-844*).—The results of a series of culture experiments running over the years 1899-1902 are given, in which the author claims that *Puccinia bardanæ* is specialized on *Lappa* spp. and *Puccinia cirsii* on *Cirsium* spp. *Puccinia violæ* is said to be autoecious on *Viola* spp., *Puccinia helianthi* autoecious on *Helianthus* spp., and *Puccinia prenanthis* specialized on *Prenanthes purpurea* and *Lactuca muralis*.

Inoculation experiments with some Uredineæ, F. BUBAK (*Centbl. Bakt. u. Par., 2. Abt., 9 (1902), No. 25, pp. 913-928, figs. 3*).—The results are given of inocu-

lation experiments with *Puccinia balsamitæ*, *Æcidium thymi*, the æcidial form of *Puccinia stipæ*; *Endophyllum sedi*, a form of *Puccinia longissima*; *Æcidium lactucinum*, which is associated with *Puccinia opizii*; *Uromyces scirpi*, and *U. pow.*

Culture methods with Uredineæ, M. A. CARLETON (*Jour. Appl. Micros. and Lab. Methods*, 6 (1903), No. 1, pp. 2109-2114).—Suggestions are given of methods for the cultivation of various Uredineæ, the methods of germination and inoculation being described and a number of suggestive studies being indicated.

Some injurious fungi occurring on cultivated plants in Dutch East Africa, P. HENNINGS (*Notizbl. K. Bot. Garten u. Mus., Berlin*, 3 (1903), No. 30, pp. 239-243).—Descriptions are given of a number of new species of fungi which are found occurring parasitically on economic plants. Among those described are *Asterina stuhlmanni* on bananas; *Microthyrium coffæ* on coffee; *Mycosphaerella tamarindi* and *Gleosporium tamarindi* on tamarind; *Macrophoma manihotis*, *Ascochyta manihotis*, and *Gleosporium manihotis* on cassava; *Trullula vanillæ* on vanilla, and *Helminthosporium tritici* on wheat.

Two new fungi from Ohio, F. BUBAK (*Jour. Mycol.*, 9 (1903), No. 65, pp. 1-3).—Descriptions are given of *Stammaria* sp., which is parasitic on species of *Equisetum*, and on *Cercospora kellermani*, which occurs on hollyhock.

Concerning the name and distribution of Urophlyctis bohémica, P. MAGNUS (*Centbl. Bakt. u. Par., 2. Abt.*, 9 (1903), No. 24, pp. 895-897).—The author discusses the identity of *Synchytrium trifolii* described by Passerini as occurring on the leaves of the common red clover and *Urophlyctis bohémica*, recently described by Bubak as parasitic on *Trifolium montanum*. Recent studies have shown that the species formerly referred to *Synchytrium* is a *Urophlyctis*, and the author believes the 2 species are identical, the proper name of the fungus being *U. trifolii*. The species seems to be widely distributed throughout Europe, where it occurs as a parasite on various cultures.

A contribution to the micology of Liguria, A. MAGNAGHI (*Separate from Atti Inst. Bot. Univ. Paria*, 2. ser., 8 (1902), pp. 13).—Lists are given of some parasitic fungi, a number of which are of considerable economic importance. New species are described as follows: *Macrophoma ligusticum* on hydrangeas, *M. helicinum* on ivy, *Cyrtospora citri* on orange, *Sphaeropsis magnoliæ* on magnolias, *Gleosporium begoniæ* on begonias, and *Colletotrichum polluceii* on Japanese loquat.

The development of a new parasitic micromycete, R. FARNETI (*Separate from Atti Inst. Bot. Univ. Paria*, 2. ser., 7 (1901), pp. 42, pls. 4).—A description is given of a new parasite of *Salvia* to which the name *Oidium hormini* is given. The development and polymorphic phases of the organism, as shown by numerous culture experiments, are fully described.

Notes on two diseases of cotton, F. FLETCHER (*Jour. Khediv. Agr. Soc. and School Agr.*, 4 (1902), No. 6, pp. 238-241).—In continuation of a previous report on the wilt disease of cotton (E. S. R., 14, p. 579), the author states that what is known in this country as sore shin, damping off, or seedling rot is responsible for a considerable portion of the loss of cotton in Egypt. In addition to this disease the cotton wilt, due to *Neocosmospora vacinfecta*, is quite prevalent, causing considerable loss, but the disease is apparently not as injurious as is reported in this country. This is believed to be due to the resistance of some Egyptian varieties to this fungus. Among the varieties in general cultivation Abbasi seems to suffer most from the wilt, and Mitaffi and Yannovitch the least. The author shows that a number of other plants are subject to attack of the wilt fungus and in arranging rotation of crops these should be carefully excluded.

Experiments with rust-resisting wheats, W. L. SUMMERS (*Jour. Agr. and Ind., South Australia*, 6 (1903), No. 7, pp. 449-455).—A report is given of cooperative experiments with 16 varieties of rust-resistant wheats, the trials being made in 9 different localities. In 1901 the crops suffered severely from rust, but during the year covered

by this report the rust did not prevail to any extent and little comparison could be made between the different varieties as to their resistance. The origin of the different varieties of wheat is given, and their relative yields and character of grain and straw compared.

Concerning the so-called brusone of wheat, V. PEGLION (*Staz. Sper. Agr. Ital.*, 35 (1902), No. 11-12, pp. 865-886).—Under the name brusone the author describes the disease of wheat that has been attributed to the fungi *Leptosphaeria herpotrichoides* and *Ophiobolus graminis*. This disease, which is commonly called the foot disease, the author apparently believes is due at times to soil conditions, and he discusses the effect of alkali and other soils on the growth and development of the plant.

Studies on the germination of ergot, S. J. ROSROWZEW (*Ber. Moskau. Landw. Inst.*, 1902, No. 3; *als. in Bot. Centrbl.*, 90 (1902), No. 25, pp. 705, 706).—The results of studies of *Claviceps purpurea* and *C. microcephala* are given.

Seed treatment for the prevention of millet smuts, L. HECKE (*Ztschr. Landw. Versuchsw. Oester.*, 5 (1902), No. 8, pp. 933-961).—Studies are reported on the effect of soaking millet seed in solutions of formalin and copper sulphate for the prevention of the smuts *Ustilago crameri* and *U. panici miliacei*. The experiments were conducted to test the effect of the fungicides on the smut spores as well as upon the germination of the seed. It was found that the smut spores were killed by soaking in formalin solutions as follows: One per cent solution for 15 minutes, $\frac{1}{2}$ per cent solution for 1 hour, or $\frac{1}{4}$ per cent solution for 3 hours. If thoroughly washed, after soaking, the strength of the solution may be materially increased and the time diminished. For practical application soaking the seed for 15 minutes in $\frac{1}{4}$ per cent solution, 1 hour in $\frac{1}{2}$ per cent, or 3 hours in $\frac{1}{4}$ per cent solutions is recommended. These treatments may be safely followed without injury to the germination of the seed. Experiments with solutions of copper sulphate were less satisfactory. The copper solutions were less efficient in destroying the fungus spores and more injurious to the vitality of the seed. The effect of neutralizing the copper sulphate solution with sodium hydroxide was tested and this fungicide prevented the germination of the spores to a slight extent only. Extensive quotations and numerous references are given to the work of other investigators who have studied the subject of soaking seed for the prevention of smut diseases.

Treatment of smuts and rusts, D. A. SAUNDERS (*South Dakota Sta. Bul.* 75, pp. 7).—Descriptions are given of the hot water and formalin treatments for oat and wheat smuts, both of which are quite efficient in preventing the diseases. For the prevention of rusts the author states that while many remedies have been tested none has been found that is effective. The burning of the stubble after thrashing is recommended and the sowing of varieties which are known to be resistant.

The prevention of oat smut and potato scab, R. A. MOORE (*Wisconsin Sta. Bul.* 98, pp. 23, figs. 3).—A description is given of the oat smut and a tabular report presented showing the proportionate amount of smutted oats in fields, the seed of which had been treated and untreated. In 172 reports from 15 counties where the seed oats had not been treated there was said to be 16 per cent of the oats destroyed through the action of the smut fungus. In 85 tests in 6 counties where the seed had not been treated the loss amounted to 18.6 per cent, while in 11 tests where the seed had been treated with formaldehyde the loss amounted to only 1.1 per cent. The author computed the loss for the entire State. Basing his figures on the total yield and the average loss as reported, he estimates that the money loss in the oat crop, due to smut, amounts to over \$5,000,000 a year. For the prevention of this heavy loss he recommends treating the seed oats with formaldehyde at the rate of 1 pt. of the 40 per cent solution to 36 gal. of water. The seed oats are placed in gunny bags and submerged in the solution for 10 minutes, after which they are spread to dry. The experiments conducted at the station and in cooperation with it have shown the

efficiency of this treatment, and the amount of fungicide mentioned above is sufficient for the treatment of from 40 to 50 bu. of oats. It is stated that through the intervention of the station at least 10,000 Wisconsin farmers treated their seed oats with this solution during the past year.

The same method of treatment is recommended for the prevention of potato scab. In this case the potatoes should be completely submerged in the liquid and left for 2 hours, or if the potatoes are very scabby for 2½ hours.

Some potato diseases (*Jour. Bd. Agr. [London]*, 9 (1902), No. 3, pp. 307-311, pls. 3).—Descriptive notes are given on the black scab, bacterial disease, and sclerotium disease of potatoes. The black scab, which is said to be due to *Cedomyces leproides*, has been previously described as occurring on beets (E. S. R., 14, p. 57). During the autumn of 1901 specimens of diseased potatoes were received from the neighborhood of Liverpool, and during the season of 1902 similarly diseased tubers were observed from a number of localities in England. On the potato the fungus produces a continuous rough, black, scab-like, thick crust, which usually commences at one or several distinct points and finally covers the entire surface of the tuber. The central portion of the diseased tubers remains sound, the fungus never spreading beyond the surface layer. If left lying on the ground the entire tuber becomes dry, eventually crumbling to pieces. Diseased tubers should be collected and burned or deeply buried, and land which has produced a diseased crop should receive a liberal dressing of lime.

The bacterial disease of potatoes due to *Bacillus solanacearum* has been reported from a number of localities, and the author recommends the spraying of the potatoes for the destruction of the leaf-eating insects as a preventive measure. If potatoes are dug as soon as the disease is indicated by the wilting of the leaves, a considerable portion of the crop may be saved by storing the tubers in a cool, dry place.

The sclerotium disease of potatoes is characterized by the growth of the fungus on the base of the stems just above the ground line. The tubers are never directly attacked by the fungus, but their growth is either checked or entirely arrested by the destruction of the above-ground parts of the plant. The fungus first appears at the base of the stem as a white, fluffy mass surrounding the stem, and after a time this mold collapses and bears numerous black bodies about the size of a grain of wheat. During the period of this development the potato stem and leaves have become wilted and both perish soon after. The only certain method of combating this disease is the collection and burning of all diseased plants. In addition to the potato, the fungus, which is *Sclerotinia sclerotiorum*, attacks a number of other garden and field plants.

A new potato disease, M. C. POTTER (*Jour. Bd. Agr. [London]*, 9 (1902), No. 3, pp. 320-323, pl. 1).—During the autumn of 1900 the author's attention was turned to potatoes presenting the irregular, tumor-like swellings characteristic of the club root of turnips. These excrescences consist of masses of thin-walled parenchymatous cells rich in starch. Spores are produced in great abundance, but all attempts to secure their germination failed. The author was able, however, to infect sound potatoes and reproduce the disease by inoculating the soil with the spores. Pot experiments are reported upon in which potatoes were grown and the disease produced, the pots being allowed to remain with the soil undisturbed until the next spring. A second planting showed that the parasite could be carried over winter by means of spores in the soil and infest succeeding crops. The author believes that the attack of the disease begins at or near the eyes of the potato, the parasite easily gaining entrance through the young and tender structures existing at those points. This disease is believed to be identical with that formerly described by Schilberszky from Hungary, which is attributed by him to the fungus *Chrysophlyctis endobiotica*. At present the author has observed the disease from but a single locality, but on

account of the possibilities of it proving to be destructive he calls attention to it and suggests that all seed tubers should be carefully examined before planting and those which are diseased be burned or deeply buried.

The potato disease, E. A. NOBBS (*Agr. Jour. Cape Good Hope*, 22 (1903), No. 1, pp. 25-29, pls. 2).—A description is given of the potato rot due to *Phytophthora infestans*, and the protection of the plants by the repeated and thorough spraying with Bordeaux mixture is recommended as a preventive treatment. In addition to *P. infestans* the author states that *Sporidesmium eritiosum* has been recently noticed as causing considerable injury to potatoes, and suggests that possibly other fungi may be found upon more critical examination.

A nematode disease of rice, J. VAN BREDÁ DE HAAN (*Meded. 's Lands Plantentuin*, 1902, No. 53, pp. 65).—This disease, which is very destructive in some parts of Java, causing the loss of from one-third to nearly the entire rice crop, is due to a hitherto undescribed nematode belonging to the genus *Tylenchus*, called by the author *T. oryzae*. The disease is characterized by a reddening and dying of the leaves in longitudinal strips. In dying, the leaves remain flat. The roots lose their white appearance, become brownish and wrinkled, and finally decay. The author describes the nematode and gives some account of its habits and life history. The adults live in the soil while the larvæ attack the roots. The disease is carried from field to field by the laborers, on tools, and by means of the irrigation water, but is never transmitted by means of seed. Methods of combating the trouble are suggested, among which are greater care to prevent its spread, providing the young rice plants with the best chance to form an abundance of good roots, and proper crop rotation in order to destroy the organism in the soil. All varieties of rice are subject to the disease, though some are less severely attacked than others.—H. M. PIETERS.

Tobacco diseases in Galicia, M. RACIBORSKI (*Abs. in Bot. Centbl.*, 90 (1902), No. 15, p. 419).—A report of studies on the diseases to which tobacco is subject is given. Among those mentioned are the diseases of roots which are said to be due to bacteria, and diseases of the stem and leaves which are caused by the fungi *Erysiphe communis*, *Sclerotinia sclerotiorum*, *Phyllosticta tabaci*, *Ascochyta nicotianae*, and *Capnopodium salicinum*. In addition to these diseases others are described which are attributed to atmospheric influences, and descriptions are also given of the mosaic disease of tobacco as well as other somewhat similar affections.

Erysiphe lamprocarpa on tobacco, G. E. ANASTASIA (*Extr. from Bul. Tec. Colliv. Tabacchi, Scufati [Salerno]*, 1 (1902), No. 1, pl. 1; *abs. in Bot. Centbl.*, 90 (1902), No. 20, p. 556).—The author claims that the form of *Erysiphe lamprocarpa* which occurs parasitically on tobacco is related to the conidial form (*Oidium tabaci*). The difference in resistance of the different varieties of tobacco to this fungus is pointed out.

Apple fungi, G. H. FRENCH, J. C. WHITTEN, J. C. BLAIR ET AL. (*Trans. Amer. Apple Growers' Cong.* 1902, pp. 76-99).—Popular descriptive notes and discussions are given of a number of the more common and destructive fungus diseases of the apple and suggestions given for their prevention. The results of experiments for the control of these diseases are given in some detail.

A contribution to the knowledge of Monilia diseases, K. SCHILBERSKY (*Magyar Bot. Lapok, Budapest*, 1 (1902), No. 5; *abs. in Bot. Centbl.*, 90 (1902), No. 20, p. 565).—The author claims that *Monilia fructigena* and *M. cinerea* are specifically related, and prefers their designation as *M. fructigena genuina* and *M. fructigena cinerea*.

The rotting and mummifying of fruits, P. PASSY (*Rev. Hort. [Paris]*, 75 (1903), No. 2, pp. 43-46, figs. 7).—An account is given of the attack of *Monilia fructigena* on apples, plums, etc., and suggestions given for its prevention.

A disease of plums, J. DUFOUR (*Chron. Agr. Canton Vaud*, 15 (1902), No. 13, pp. 375-378, figs. 2).—Descriptions are given of the effects produced by the fungi *Eroas-*

ens pruni, *E. deformans*, and *E. cerasi* upon their host plants, and suggestions given for combating their injurious attacks.

Notes on a disease of lemons in Sicily, G. BRIOSI and R. FARNETI (*Separate from Atti Inst. Bot. Univ. Paria*, 2. ser., 8 (1902), pp. 4).—A description is given of a very serious disease of lemons that is known in Sicily as the white rust. A study of the materials sent the authors led them to decide that the disease was due to an undescribed species of *Ovularia* to which the name *O. citri* is provisionally given. The fungus is possibly related to and greatly resembles the *Oospora hyalinula* of Saccardo.

Diseased cocoanut palms (*Agr. News [Barbados]*, 2 (1903), No. 23, p. 67).—A brief account is given of some diseases of the cocoanut palm, some of which have been previously described (*E. S. R.*, 14, p. 671).

Raspberry cane blight and raspberry yellows, F. C. STEWART and H. J. EUSTACE (*New York State Sta. Bul.* 226, pp. 331-366, pls. 6).—Preliminary to a complete account of the diseases of the cultivated raspberries, blackberries, and dewberries, the authors describe a disease that has proved exceedingly destructive to the raspberry. This disease, under the name cane blight, was previously briefly mentioned (*E. S. R.*, 13, p. 149) and appears to have escaped the attention of vegetable pathologists. Their observations begun in 1899 were extended through subsequent seasons and results of their studies are given in the bulletin.

The cane blight attacks both red and black raspberries and occurs probably on the dewberry, but so far as their observations go the blackberry is exempt. The principal damage is done to the fruiting canes, although the new shoots are attacked and occasionally killed during the first season of their growth. The foliage on the affected canes wilts suddenly and becomes dry, involving either the whole cane or only a portion. It is most conspicuous about fruiting time, and canes loaded with ripening fruit suddenly wilt and dry up. The disease does not spread from a center, but canes here and there throughout the plantation are affected, and thrifty, well-cared-for plantations appear to suffer as well as neglected ones. In general the disease is more destructive in old plantations, and the virulence seems to increase with the age of the plants.

The disease is of fungus origin, and is due to an undetermined species of *Coniothyrium*, closely related to if not identical with *C. fuckellii*. Inoculation experiments have shown that the disease can be readily produced by inserting the spores of the fungus, both old and new canes yielding to the disease within 2 months after inoculation. Investigations as to the time and manner of natural infection seem to indicate that the new canes are attacked in the late summer or autumn, although there is evidence that infection may occur on the fruiting canes early in the spring. The fungus seems to gain entrance through wounds, particularly those produced by the snowy tree-cricket (*Eucanthus niveus*).

During August and September the new canes of red raspberries frequently show a brownish or bluish-black coloration, extending more or less around the canes. These were supposed to represent the initial stage of the cane blight, but the authors' investigations show that the discoloration is due to *Sphaerella rubina*, a rather common fungus which is not of very great importance. Spraying experiments for the prevention of the cane blight have proved futile, in one case the spraying apparently increasing the disease. Preventive measures are suggested, by which the disease may be kept in check, it being recommended that healthy plants be chosen, that all diseased canes be removed, and the general health of the plants protected by the use of fungicides.

The Marlboro red raspberry apparently is subject to a disease which is quite destructive to that variety, although not confined entirely to it. This disease the authors designate as raspberry yellows and the affected plants have a stunted yellowish appearance suggestive of peach yellows and the Bermuda lily disease. On

fruiting canes the fruit-bearing shoots are dwarfed, the leaves are small, curled, and faintly mottled with yellow. Many of the berries dry up without ripening, and those that ripen are small and insipid. This disease is apparently quite an important one, and is to be the subject of further investigation. At present it is believed to be not of fungus origin, and experiments with fertilizers have been without any appreciable effect.

Two new raspberry diseases, F. H. HALL, F. C. STEWART, and H. J. EUSTACE (*New York State Sta. Bul.* 226, popular ed., pp. 11, figs. 2).—A popular summary of the above bulletin.

The preventive treatment of oidium, DE BOISSARD (*Rev. Vit.*, 18 (1902), No. 469, pp. 672, 673).—The writer calls attention to the fact that for 9 years he has successfully combated the occurrence of powdery mildew on grapes by washing the stock with a 10 per cent solution of copper sulphate. The vines are heavily sprayed or washed with this solution during their dormant period, and as a result the following season no trace of mildew has been observed. This treatment not only destroys the fungus spores, but also mosses and lichens which may be present upon the grapevines, as well as being destructive to numerous insects which are found in the cracks of the bark.

Brunissure, P. VIALA (*Rev. Vit.*, 18 (1902), No. 467, pp. 610, 611, pl. 1).—The author reviews previous investigations regarding the cause of brunissure, describes its characteristics, and suggests its possible causes.

The brown rot disease of redwood, H. VON SCHRENK (*U. S. Dept. Agr., Bureau of Forestry Bul.* 38, pp. 29-31, pls. 2).—The only disease of the redwood of any particular importance is said to be that known as butt, brown, or pin rot. The brown rot causes the wood to become very brittle, having properties quite similar to charcoal. The decay starts in the inner rings of the heartwood and extends outwardly until all the heartwood is pitted. The brown rot starts at or near the ground and extends from the roots upward into the trunk for distances varying from 3 to 50 ft., but as a rule does not go more than 10 or 15 ft. into the butt. So far the author has not been able to identify any fungus as the cause of this disease, but from the close resemblance of the brown rot to a similar disease of *Libocedrus decurrens* it is thought possible that the two may be due to the same or related species of fungi. The brown rot does not cause any great amount of damage and measures for its prevention are impracticable. The decay of redwood poles used for telegraph and other purposes has been observed, which is similar to the brown rot, and it is recommended that this decay could be probably retarded by the thorough drying of the poles before setting them or by coating with some preservative substance.

A disease of the white ash caused by *Polyporus fraxinophilus*, H. VON SCHRENK (*U. S. Dept. Agr., Bureau of Plant Industry Bul.* 32, pp. 20, pls. 5).—A description is given of the white rot of ash caused by the growth of *Polyporus fraxinophilus* in heartwood of the trunk and branches of the white ash. This fungus changes the wood into a soft, pulpy, yellowish mass, making it unfit for lumber purposes. A diseased tree may be readily recognized by the conspicuous sporophores which usually occur in considerable numbers about every dead branch or stub. The fungus attacks ash trees of all ages, usually, however, those that are more than 7 in. in diameter. It begins growth in a wound or a dead branch and spreads to the main trunk. A technical description is given of the fungus and the microscopic changes which the wood undergoes. As a result of experiments the author has found that the fungus will not grow very well in dead wood. As preventive measures in parks and grounds the diseased trees should be cut down and in pruning wounds should be covered with some antiseptic.

A new orchid parasite, L. MONTEMARTINI (*Separate from Atti Inst. Bot. Univ. Pavia*, 2. ser., 8 (1902), pp. 3, pl. 1).—A description is given of *Uredo aurantiaca*, n. sp., a rust fungus recently discovered attacking the leaves of the orchid (*Ocnidium*

carendishianum). The fungus is technically described and its effect on the host plant shown.

A pelargonium disease, G. MASSEE (*Jour. Roy. Hort. Soc. [London]*, 27 (1902), p. 172; *abs. in Bot. Centbl.*, 91 (1903), No. 1, p. 15).—A description is given of a rust of Zonal Pelargoniums which is caused by *Puccinia granularis*. This fungus is said to be not uncommon on various wild plants belonging to the family Geraniaceae and in all probability passed to imported cultivated forms from the indigenous species.

Fairy ring spot of carnations, P. VOGLINO (*Extr. from Ann. R. Accad. Agr. Torino*, 45 (1902), pp. 1-13, pl. 1; *abs. in Bot. Centbl.*, 90 (1902), No. 6, p. 165).—A description is given of a disease which has been variously called smut of carnations, fairy ring spot, etc., which is due to the fungus *Heterosporium echinulatum*. The author objects to the designation "smut," claiming that this name should be retained for diseases caused by various species of Ustilagineae. The pathological conditions produced by the fungus are described as well as its spore formation and other characters. The fungus occurs in the leaves and results in the malformation of the flowers. The disease develops rapidly and is readily reproduced artificially, infections being produced within a day or two.

Preliminary efforts to develop a continuous process of seed disinfection by means of formaldehyde vapor, H. L. BOLLEY (*Proc. Soc. Prom. Agr. Sci. 1902*, pp. 74-81, pl. 1).—In experimenting with formaldehyde as a disinfectant for seeds, the author made a particular study regarding the disinfection of flaxseed, which, on account of its nature, does not admit of soaking or sprinkling. For treating this seed it is necessary to submit it to vapor, and passing the seed continuously through the vapor was believed to give the best results. Various forms of apparatus were devised, which are figured and described. The preliminary efforts made at disinfecting flaxseed by means of formaldehyde gas are said to have produced good results. As to the use of gas treatment upon other grain there seems to be little probability that methods will be found less tedious or difficult than the simple method of sprinkling with the fungicide.

The use of the centrifuge in diagnosing plant diseases, H. L. BOLLEY (*Proc. Soc. Prom. Agr. Sci. 1902*, pp. 82-85).—The author discovered while examining samples of grain in a centrifuge that this machine could be used for diagnosing plant diseases. The method is quite simple. It consists merely of placing a sample of the seed grain shaken with distilled water in the tubes and examining the sediment with a microscope. This method is so effective that spores of smuts could be detected in samples of seed which would otherwise be pronounced free of all smut. In a study of flaxseed it was found that gasoline could be used in place of water to considerable advantage. While examining the flaxseed for the wilt disease the author found that in addition to the *Fusarium lini* a number of other fungi are almost as constantly present as the *Fusarium*, and it is probable that they exert a considerable influence on the production of the flax wilt. In a study of flaxseed it was shown that the spores of *Fusarium lini* are almost universally distributed throughout the flax belt and were present in over 85 per cent of all samples examined.

Early spraying as a means of protection against spring frosts, L. DEGRULLY (*Prog. Agr. et Vit. (Éd. l'Est)*, 24 (1903), No. 9, pp. 257, 258).—Heavy applications of a solution of 40 to 50 kg. of iron sulphate in 100 liters of water made just before the buds begin to swell are said to be beneficial in reducing various grape diseases and also by temporarily checking the growth of grapevines to greatly lessen the liability to late spring frosts. The effect is only temporary and growth is checked for but a short time. Experiments are to be conducted to ascertain how long the protective influence may be exerted.

The reduction of lime in fungicides sprayed upon leaves, G. E. MARCHETTI (*Staz. Sper. Agr. Ital.*, 35 (1902), No. 11-12, pp. 922-925).—A discussion is given of some of the changes that take place in the lime in Bordeaux mixture and other fungicides when exposed upon leaves.

ENTOMOLOGY.

Thirty-third annual report of the Entomological Society of Ontario, 1902 (*Rpt. Ontario Ent. Soc. 1902, pp. 133, pls. 3, figs. 108*).—This report contains the proceedings of the thirty-ninth annual meeting of the Entomological Society of Ontario, held in London, October 29 and 30, 1902, and the proceedings of the fourth annual meeting of the Northwest Entomological Society, held at Calgary, November 5, 1902: At these meetings a number of papers were read, among which the following may be briefly noted:

The pea weevil, J. Fletcher and W. Lochhead (pp. 3-15).—The serious nature of this pest in Canada was discussed by both speakers. It is suggested that the insect might be nearly or quite exterminated by adopting the proper measures. The remedies recommended include holding over the seed until the second year, treating it with kerosene, or fumigating it with bisulphid of carbon. The last-named remedy is considered the most effective. Farmers are urged not to sow infested peas, to harvest the crop as soon as ripe, and thrash at once, and to treat seed peas as soon as convenient.

Report on injurious insects in 1902, G. E. Fisher (pp. 15-22).—Biological and economic notes on cankerworm, pear psylla, white-rose scale, and San José scale.

Insect life, T. W. Fyles (pp. 23-31).—The author presents biological notes on a number of common insects, including periodical cicada, *Catocala parta*, syrphus flies, lace-winged fly, and various parasites.

W. Lochhead (pp. 31-36) gave notes on the life and work of a number of experts on Lepidoptera. C. H. Young (pp. 37-44) presented brief notes on the birch skeletonizer, tomato worm, zebra caterpillar, cabbage butterflies, tent caterpillar, codling moth, white-marked tussock moth, potato beetle, asparagus beetle, etc. C. Stevenson and J. A. Moffat (pp. 57-60) gave short biological accounts of *Alaus oculatus*, tent caterpillar, cressphontes butterfly, asparagus beetles, and cabbage butterfly. H. H. Lyman (pp. 61-63) gave a brief account of the life history and habits of *Danaus archippus*. W. Lochhead (pp. 64-69) reported observations on Hessian fly, pea weevil, clover-seed midge, wireworms, cutworms, squash bug, potato-stalk borer, codling moth, apple maggot, plum curculio, and bud moth. T. W. Fyles (pp. 69-74) gave notes on the paper-making wasp of Quebec, its habits, structure of nest, etc. A. Gibson (pp. 74-78) read a paper on Some Interesting Habits of Lepidopterous Larvæ. The species noted included *Procris americana*, tent caterpillars, *Phlyctenia ferrugalis*, brown-tail moth, etc. The same author (pp. 79, 80) gave a brief account of the injuries caused to the American larch by *Semioophora youngii*. J. Fletcher (pp. 80-92) presented economic notes on pea aphid, grasshoppers, pea weevil, blister beetles, San José scale, grape-vine leaf hopper, pear slug, and Mediterranean flour moth. W. Lochhead (pp. 101-114) gave an analytical key for the identification of insects injurious to apple, plum, cherry, and peach trees. W. H. Herrington (pp. 114-117) gave an account of the life history of *Monohammus confusor*, *M. scutellatus*, etc., injurious to pines.

The Northwest Entomological Society decided to abandon its organization and voted to establish a new society under the title: The Territorial Natural History Society.

Second report of the State entomologist, W. E. BRITTON (*Connecticut State Sta. Rpt. 1902, pt. 2, pp. 99-178+N, pls. 15, figs. 19*).—A copy is given of the insect-pest law of Connecticut, together with a brief outline of entomological work for the year, and the organization, equipment, and publications of the department. A list is given of nursery firms which received certificates during 1902.

In a series of experiments to destroy the San José scale crude oil undiluted and in 25 per cent mixture with water, kerosene in 25 per cent mixture with water, soda soap (1 lb. per gallon of water), Naphcin ($\frac{1}{2}$ pt. in 2 gal. of water), and lime-sulphur-salt mixture were used. Where the 25 per cent crude oil or kerosene were used on

pear trees no living insects were found on the following May. About 13 per cent were found to be alive on apple trees sprayed with the same mixtures. Lime-sulphur-salt wash was used on plum and peach trees and proved very effective without injuring the trees. Naphcin was of little use. The owners of a large orchard sprayed 7,000 trees just before the buds opened, with the California mixture. The author examined the orchard in July and August and found that the insecticide had proved exceedingly effective. Oil was also used by many orchardists with satisfactory results in most cases. Soda soap proved to be of little value. The California wash was used by orchardists in a number of large peach orchards with satisfactory results. In November, 1902, 3 large apple trees were fumigated with hydrocyanic-acid gas. An examination made on January following showed that no living insects remained. The author's general recommendations in the treatment of San José scale is to remove worthless trees, burn out injured branches, and spray during the winter months with California wash.

A number of natural enemies of the San José scale were observed in this State. *Chilocorus bicallosus* were very abundant and nearly exterminated the scales on some trees. *Pentilia misella* was also efficient in the destruction of scales. A fungus enemy was observed and is believed to be a species of *Capnodium*. A circular letter was sent out to entomologists and horticultural inspectors to obtain evidence concerning the relative degree of infestation of different plants by the San José scale. From the 45 replies obtained from the 80 circulars sent 3 lists of plants are prepared according as the plants are badly infested, occasionally infested, or not infested.

Brief notes are also given on apple-tree tent caterpillar, white fly, brown-tail moth, raspberry-cane maggot, hickory-bark borer, currant worm, asparagus beetles, spinach-leaf miner, *Anisota scrutatoria*, *Anomala binotata*, *Aspidiotus forbesi*, etc. The elm trees in New Haven and elsewhere were observed to be considerably pruned by gray squirrels. It appears that these animals cut off the twigs so as to obtain the seeds upon the ground. It is stated that the report concerning the presence of the brown-tail moth in Connecticut is unfounded.

Report of the State entomologist on the noxious and beneficial insects of the State of Illinois, S. A. FORBES (*Twenty-first Rpt. State Ent. Illinois, 1900, pp. 184+XVIII, pls. 13, figs. 97*).—This report contains a reprint of Bulletins 56 and 60 of the Illinois Station (E. S. R., 11, pp. 654, 655; 12, p. 866).

Report of the State entomologist on the noxious and beneficial insects of the State of Illinois, S. A. FORBES (*Twenty-second Rpt. State Ent. Illinois, 1903, pp. 149+XX, pls. 9, figs. 32*).—A portion of this report consists of reprints of Illinois Station Bulletins 71, 72, 79, and 80 (E. S. R., 14, pp. 270, 271, 673, 675). The parts of the report which have not been previously noted may be referred to in this connection:

Experiments and observations on the use of crude petroleum and pure kerosene for the San José scale (pp. 91-95).—In these experiments crude petroleum and kerosene were sprayed on March 12 and 15 upon 52 trees, including apple, cherry, pear, and peach; 31 trees were treated with kerosene and 21 with crude oil. On June 15 no living scales could be found on any of the trees except 3 badly infested apple trees. No injury was noted except upon the peach trees, and of the 24 which were treated only 4 escaped injury. In an examination of 40,398 trees sprayed with crude oil in the Catawba Island district of Ohio it was found that only 6,448 were entirely without injury. As stated in the following proportion, 16 per cent were uninjured, 54 per cent slightly injured, 15 per cent seriously so, 7 per cent nearly killed, and 8 per cent killed outright.

Experiments with summer washes for the San José scale (pp. 96, 97).—A kerosene emulsion with whale-oil soap, containing 10 per cent kerosene; and a mixture of soda, potash, sulphur, and whale-oil soap were used. The latter insecticide was applied to 58 trees infested with San José scale. Detailed notes are given on these

experiments. It was found that the 2 summer washes which were used destroyed only young scales and served merely as a slight temporary check upon the spread of the insect.

On the principal nursery pests likely to be distributed in trade (pp. 98-138).—These notes on a large number of insects and fungus diseases observed upon various economic plants are of especial interest on account of the possibility of their being spread by nursery trade.

The cankerworm on shade and forest trees (pp. 139-144).—At Jacksonville, Ill., great injury was done to elm trees by the cankerworm. Bands of gas-tar and other material was applied to the trees and 199 trees were sprayed with arsenite of lime, at a cost of about 84 cts. per tree. In the spring further banding operations were carried on. The insecticide operations seemed to give promise of good results.

The Colaspis root worm (pp. 145-149).—*Colaspis brunnea* was observed injuring the roots of corn. The damage consisted chiefly in eating away the tap root. Other insects were associated with the *Colaspis* in this work. Descriptive and economic notes are given on this species. Until further details are learned concerning its life history it is impossible to recommend successful remedies.

Second biennial report of the Montana State Board of Horticulture, 1901-2, C. H. EDWARDS (*Montana State Bd. Hort. Rpt. 1901-2, pp. 125, pls. 30*).—A copy is given of the law creating the Montana State Board of Horticulture and prescribing its powers and inspection duties. The rules and regulations adopted by the board are also presented together with an account of the meetings of the Board and business transacted. The State has been divided into inspection districts with an inspector in charge of each district, and the reports of the different inspectors contain notes on the special conditions of the orchards and nurseries in different parts of the State with reference to the prevalence of insect and fungus diseases.

The codling moth is considered the most important pest with which the board has to deal, this insect having recently secured a foothold in Helena, Missoula, and elsewhere. The San José scale has not been found in Montana. Notes are given on clover mite, red spider, root nematodes, plum curculio, crown gall, oyster-shell barklouse, apple-bud moth, apple-tree anthracnose, flat-headed apple-tree borer, woolly aphis, etc., and remedies are suggested for controlling these pests.

Nursery inspection in West Virginia, J. H. STEWART (*West Virginia Sta. Rpt. on Nursery Inspection, 1901 and 1902, pp. 64, pls. 5, fig. 1*).—During the work of inspecting nurseries and orchards of West Virginia it was found that all nurseries, with one exception, were apparently free from dangerous insects and fungus diseases. In the prosecution of this work 98 orchards, growing 270,000 trees, were inspected, and the San José scale was found on about 141,000 of these trees in 55 orchards. These orchards included fruit trees of various kinds. Detailed notes are given on the conditions found in the various orchards. San José scale was thus found to be generally scattered throughout the State. Notes are given on the habits and life history of this insect and on the treatments which have been found most effective in combating it. These remedies include the encouragement of natural enemies, the destruction of infested plants, spraying with oils, whale-oil soap, and the California wash. Notes are also given on various other diseases and dangerous insects which are mentioned in the State law concerning insect and fungus pests. As a result of the experimental insecticide work conducted in this State it was found that crude petroleum or any of its local products will kill San José scale, but is also likely to injure fruit trees if used undiluted. When mixed with 3 or 4 parts of water this substance was as effective in destroying the scale as when used in somewhat greater strength. Kerosene was found to be equally as effective as crude petroleum. The author believes from his experiments that paraffine is the constituent of oil which is most likely to injure trees.

Proceedings of the Entomological Society of Washington (*Proc. Ent. Soc. Washington*, 5 (1903), No. 3, pp. 167-236, figs. 7).—Among the articles contained in this number of the proceedings the following may be mentioned: Recent Work in North American Lepidoptera; A New Genus and Species of Geometridæ; North American White-Marked Species of Eucosma; Lepidoptera Collected at Williams, Ariz., by H. G. Dyar. W. A. Ashmead read a paper on New Genera in the Cynipoidea; N. Banks, on Brachynemuri of the *B. ferax* Group; A. Busck, on Brackenridge Clemens' Types of Tineina, and on Dimorphism in the Codling Moth. A. N. Caudell presented a paper on Nomenclature of Blattide. The form of codling moth is described as a new variety under the name *Cydia pomonella simpsonii*.

Report on injurious insects and plant diseases in 1902, W. M. SCHÖYEN (*Beretning om Skadeinsekter og Plantesygdomme i 1902. Christiania, 1903, pp. 46, figs. 21*).—As in other annual reports by the author, attention is called to the more important insect outbreaks during the season. A large number of injurious insects are mentioned, being classified according to the plants to which they were injurious. On cereals the chief injuries observed were due to crane flies, grain aphids, and frit fly. Grasses were attacked by *Charwas graminis* and *Cleigastra flavipes*. Clover was injured to considerable extent by *Sitones lineatus*. Notes are also given on the pea weevil, cabbage-root maggot, *Halitica nemorum*, cabbage worms, tarnished plant bug, pear-tree psylla, pear-leaf blister-mite, apple scab, black rot of apples, currant sawfly, *Bombix pini*, *Rhizotrogus solstitialis*, *Lophyrus rufus*, etc.

Injurious insects, E. FLEETIAUX (*Jour. Agr. Prat. Pays Chauds*, 2 (1903), No. 10, pp. 495-502).—Brief notes are given on insects injurious to sugar cane in Java, and on a weevil which attacks the banana in Madagascar. This weevil was determined as *Sphenophorus sordidus*. A list is also given of injurious insects captured in Guadalupe.

Recent experience with destructive insects, MARY E. MURTFELDT (*Missouri State Hort. Soc. Rpt. 1902, pp. 253-258*).—Economic and biological notes on canker-worm, tarnished plant bug, leaf hoppers, raspberry-cane borer, etc.

A new enemy of cereals, F. MALMEJAC (*Meun. Française*, 18 (1902), Nos. 197, pp. 6-8, figs. 19; 198, p. 33; 199, p. 56; 200, p. 79; 201, p. 105, 106; 202, pp. 135, 136).—The author describes a new species, under the name of *Pentatoma triticum*, a bug which is said to have caused considerable damage to wheat. The insect is described in considerable detail and elaborate notes are given on the character of the damage caused by its attacks. It was found to attack chiefly the heads of wheat and more rarely the leaves and other parts. Low temperatures are said to be unfavorable to the species, and it can be destroyed by applications of kerosene emulsion. The insect attacks wheat during the formation of the grain and even after the kernel is dry. The effect of this attack is to increase the moisture and sugar content and to diminish the proteid content.

Hessian fly experiments, H. GARMAN (*Kentucky Sta. Bul. 103, pp. 229-244*).—The purpose of these experiments was to determine the time at which wheat may be planted so as to escape the Hessian fly and avoid injury from freezing. Wheat planted in the fall of 1901 in Kentucky produced rather a poor crop. This was attributed by some to late planting, by others to the Hessian fly, but the author believes it was due to bad weather at the time of planting. It appears that eggs laid late in the season do not hatch. On some infested plats wheat was planted again in the fall of 1902, beginning September 15. The earliest plantings were injured to the extent of 37 per cent, while plats planted from October 13 to 27 were not infested. According to the author's observations, wheat that escapes injury in the fall will be injured in the spring in proportion to its nearness to fall infested wheat.

Experiments were made in the use of air-slaked lime, lime and Paris green in water, Bordeaux mixture, and kerosene emulsion. The following percentages of

infestation were observed on plats thus treated: After lime, 25 per cent; after lime and Paris green, 31 per cent; after Bordeaux mixture, 19 per cent; after kerosene emulsion, 9 per cent; untreated trees being infested to the extent of 38 per cent. The author believes that kerosene emulsion might be used on a large scale with good results. It was also found that plowing to a depth of 6 in. greatly reduced the number of flies which emerged. The number of broods of Hessian fly in Kentucky is believed to be 3 per year. Barley was attacked about as badly as wheat, while rye was but little infested. Brief notes are also given on *Isosoma grande*. The author recommends that in order to prevent severe injury in the fall from the Hessian fly wheat should not be planted before October 6.

Woolly aphid or American blight, W. W. FROGGATT (*Agr. Gaz. New South Wales*, 14 (1903), No. 1, pp. 18-25, figs. 5).—The author presents a brief account of the history and distribution of this insect. A few experiments were made in combating the pest. It was found that by scraping away the earth for a distance of 2 ft. around the trunk and exposing the main roots, 3 lbs. of tobacco leaf laid upon the roots and again covered with dirt was sufficient to destroy the insect. It is considered advisable to cut off the larger galls before applying the tobacco. Treatment with bisulphid of carbon was found to be exceedingly effective, but rather too expensive for the ordinary orchardist. A brief bibliography of articles relating to the woolly aphid is also given.

Investigating the codling worm, M. O. COLE (*Missouri State Hort. Soc. Rpt. 1902*, pp. 318-320).—By the use of bands the author determined that a large percentage of the larvæ of the codling moth crawl down the trunks of the infested trees and may be caught under bands. On 1 tree 400 larvæ were captured in this way, and it is estimated that this was only a portion of the worms which infested apples on that tree.

The periodical cicada and its occurrence in Maryland in 1902, A. L. QUAINANCE (*Maryland Sta. Bul.* 87, pp. 65-116, pls. 3, figs. 17).—The author discusses the life history, egg laying, and feeding habits of this insect. Considerable injury may be done by the punctures produced by the cicada while feeding. Both sexes were found to have functional stomachs in which the sap of trees was found by dissecting specimens. Notes are given on the 2 races of cicada and on the dwarf variety, and the insect is described in its various stages. A brief account is presented of the natural enemies of the cicada, the other broods which occur in the State, and detailed notes are given on the distribution of the swarm which occurred in 1902. In combating this insect the author recommends that special attention be given to trees during the coming winter and spring, in order to prevent further injury to the trees by the woolly aphid, which locates upon the scars caused by the cicada. The adults may be destroyed by kerosene emulsion or pyrethrum powder, but where they occur in large numbers no remedy is perfectly effective.

Insect enemies of the redwood, A. D. HOPKINS (*U. S. Dept. Agr., Bureau of Forestry Bul.* 38, pp. 32-40, figs. 4).—Descriptive and economic notes are presented on *Vespa marina sequoie*, *Phlecosinus sequoie*, *P. cupressi*, *P. cristatus*, and white ants. The literature upon the subject of insect enemies of the redwood is rather meager and the species mentioned include the most important ones which attack these trees. Few attempts have been made to control these insects and the recommendations regarding remedies are therefore confined largely to an outline of preventive measures. It appears from observations made by a number of persons that the California redwood is immune to the attacks of white ants.

Insect enemies of the evergreens, E. A. POPENOE (*Industrialdist*, 29 (1903), No. 17, pp. 263-273).—Notes are given on the habits and life history of *Tomicus caco-graphus*, *Chalcophora virginensis*, *Monohammus confusor*, pine-scale louse, red spider on cedar trees, *Monotinus unicolor*, *Phlecosinus dentatus*, etc.

Lime, sulphur, and salt wash, C. L. MARLATT (*U. S. Dept. Agr., Division of Entomology Circ. 52, 2. ser., pp. 8*).—On account of the recent experiments which have shown the effectiveness of this insecticide in Eastern States, the author prepared a brief account of the history of this insecticide, its effect upon scale insects, and the method of preparing and applying it.

The result of applying crude petroleum to peach trees in Ohio to suppress the San José scale, F. M. WEBSTER (*Proc. Soc. Prom. Agr. Sci. 1902, pp. 119-140, pls. 4*).—A controversial article concerning the value of this insecticide, with special reference to the possible danger from its application. Instances are noted from experiments in Ohio in which great damage was done to peach and other trees.

Crude petroleum as an insecticide, E. P. FELT (*Proc. Soc. Prom. Agr. Sci. 1902, pp. 86-95*).—The results obtained from the experiments of various entomologists with this insecticide are briefly discussed and a number of conclusions are drawn from the results thus far obtained. The effect of crude petroleum and the comparative safety in using it have been estimated quite frequently by different investigators. A brief bibliography of the subject is added to the article.

Insecticides for use in Hawaii, D. L. VAN DINE (*Hawaii Sta. Bul. 3, pp. 25, figs. 7*).—A short general account of the application of insecticides, spraying apparatus, and a discussion of the formulas and means of preparing the common insecticides of various sorts, such as Paris green, arsenate of lead, soda arsenite of lime, pyrethrum, hellebore, arsenic-and-bran mash, kerosene emulsion, whale-oil soap, resin wash, carbon bisulphid, and hydrocyanic-acid gas.

Liquid and dust spraying, J. C. EVANS ET AL. (*Missouri State Hort. Soc. Rpt. 1902, pp. 215-223*).—A number of points connected with the comparative value of liquid and dust sprays were discussed by different speakers. The insect which was chiefly considered in this discussion was codling moth.

Spray calendar, F. H. BLODGETT and T. B. SYMONS (*Rpt. Maryland State Hort. Soc., 5 (1902), pp. 156-163*).—Directions are given with regard to the more important insecticide and fungicide operations required during the different months of the year. The chief insect and fungus pests are briefly mentioned, with formulas for insecticides and fungicides.

A practical means of destroying cockroaches, C. CHALOT (*Jour. Agr. Prat. Pays Chauds, 2 (1903), No. 10, pp. 503, 504*).—In combating *Periplaneta americana* the author had best success from trapping the insects in glass vessels containing a small quantity of olive oil and being inclined at an oblique angle so as to make it possible for the cockroaches to enter the neck of the vessels.

The culture of the mulberry silkworm, HENRIETTA A. KELLY (*U. S. Dept. Agr., Division of Entomology Bul. 39, n. ser., pp. 32, figs. 15*).—This bulletin constitutes a brief handbook of information regarding the various processes and manipulations of sericulture. The information was obtained by travels and observations in Italy and France, and by practical experience under sericulturists in these countries. The subjects discussed include the life history of the silkworm, the food plants, instruments necessary for use in silkworm culture, hatching of the eggs, rearing of silkworms, preparations for spinning, preparing the cocoons for market, and the diseases of silkworms.

Silkworm culture, HENRIETTA A. KELLY (*U. S. Dept. Agr., Farmers' Bul. 165, pp. 32, figs. 16*).—A reprint of Bulletin 39, Division of Entomology, with the addition of a few paragraphs relative to the culture of the mulberry (noted above).

Pebrine and related microsporidia, A. LUTZ and A. SPLENDRE (*Centbl. Bakt. u. Par., 1. Abt., 33 (1903), No. 2, Orig., pp. 150-157, fig. 1*).—Notes are given on the various species of *Nosema* which occur in silkworms and other insects. A list is presented of the various insects and fish in which these organisms are found and a brief synoptical table is given for identification of the species of *Nosema*.

FOODS—NUTRITION.

Third report on food products for 1902, B. W. KILGORE (*Bul. North Carolina State Bd. Agr.*, 24 (1903), No. 1, pp. 78).—In carrying out the provisions of the State pure-food law a number of analyses were made which are reported and discussed. In addition to a general summary the bulletin contains the following special articles: Canned Fruits and Vegetables; Bottled Non-Alcoholic Carbonated Beverages—Summer Drinks; Phosphates, Malts, Ciders, and Bitters; Tomato Catsup and Sauces; and Prepared Mustards and Salad Dressings, by W. M. Allen. Cheese; Butter, Renovated Butter and Butterine; and Lard and Compounded Lard, by J. M. Pickel. Baking Powders, by B. W. Kilgore and W. M. Allen. Flour; Corn Meal; and Commercial Stock Feeds, by F. C. Lamb. Condimental Stock Foods and Condition Powders, by T. Butler and F. C. Lamb.

In the last article the authors report analyses of a number of condimental feeds recommended for horses, cattle, and poultry, as well as one recommended as a cure for hog cholera. These feeds were found to consist of such common articles as wheat bran or similar products, linseed meal, charcoal, salt, saltpeter, sulphur, dried blood, fennugreek, red pepper, etc. According to the authors—

“It may be freely stated that the so-called condimental stock foods and condition powders on the market, when tested by accurate and practical feeding trials, when judged as medicines, when compared in price with other materials of the same feeding value, or when measured by the claims made for them by the manufacturers, fail to show merit sufficient to justify their use.

“If the live stock is well and properly cared for and fed, it needs no medicine. If care and feed are needed, the best may be had in any market for less than one-tenth that charged for it when put up in 1 or 2 lb. packages and advertised as ‘stock food’ or ‘condition powder.’

“The question often arises, Why is it if these stock foods are all frauds that so many honest and intelligent men think they have obtained good results from their use? The answer is not difficult. There is in every organism an inherent tendency to return to normal conditions, or, in other words, to get well if sick. When a man gets to the point of buying condition powders for an animal he is ready to give him the better care and food which alone would and does bring about the desired improvement in condition. The ‘stock food’ gets the credit, although it does contain nothing but wheat bran, charcoal, and pepper and salt. If it is a tonic that the horse, cow, or pig is in need of, why not purchase gentian, iron, and nux vomica direct from the druggist. They will not only cost less, but if medicine is really needed, are much more likely to produce the desired effect.”

On the digestibility and availability of food materials, W. O. ATWATER (*Connecticut Storrs Sta. Rpt. 1901*, pp. 179–245).—The results of 50 digestion experiments, generally of 3 or 4 days' duration, with 3 healthy young men whose digestive powers were believed to be unimpaired are reported. As a whole the experiments formed a part of the investigations on the metabolism of matter and energy carried on with the respiration calorimeter, 18 being conducted while the subjects were outside the apparatus and 32 with the subjects inside the respiration chamber. The diet was simple, being made up of a number of common-food materials of animal and vegetable origin. In 18 tests the nutrients were provided in about the same proportion as in the ordinary diet; in 17 tests the diet furnished large quantities of fat, and in 14, large quantities of carbohydrates, though the energy in these cases was not greater than was needed to supply the demands of the body under the experimental conditions.

So far as was observed individual peculiarity did not affect the digestion of the several nutrients. “With each subject the range of variation in the results of similar

experiments is much wider than the differences between the averages of similar experiments with different subjects."

The sojourn in the calorimeter (i. e., confinement under somewhat abnormal conditions) had little influence on the digestibility of the food. It is said in effect that increasing the quantity of either carbohydrates or fat above those common in the ordinary diet had no influence upon the digestibility of the other nutrients of the diet, while the digestibility of the fat or the carbohydrates in the experiments in which either was used in large quantities was as large, or larger than, in the experiments in which the quantities were more nearly like those in the ordinary diet. In these experiments more or less severe muscular work had no apparent effect upon the digestibility of the different nutrients of the diet.

"It made practically no difference whether the men were as quiet as possible, or were engaged in very light, or moderate, or severe muscular work, the proportions of unavailable material rejected by the intestine were no larger in one case than in the other. That is to say, so far as the using up of the nutrients of the food was concerned, the amount of muscular exercise made no appreciable difference."

Judging by the results of these experiments it appears that on an average the coefficients of digestibility of the nutrients in a mixed diet are: Protein 92 per cent, fat 95 per cent, and carbohydrates 97 per cent. These factors it is noted depend considerably upon the proportions of animal and vegetable foods in the diet, as the digestibility of the nutrients is different in different materials, the protein of animal foods, like meat and milk, being more completely digested and utilized than that of most vegetable foods, like beans or potatoes. The digestibility of the protein of mixed diet will therefore vary according as it contains a larger or smaller proportion of animal food. Roughly speaking, however, about 95 to 96 per cent of the total organic matter and 91 to 92 per cent of the total energy of mixed diet will be digestible.

Percentage composition and pecuniary value of human foods, J. KÖNIG (*Prozentige Zusammensetzung und Nährgehalt der menschlichen Nahrungsmittel. Berlin: J. Springer, 1902; rev. in Ztschr. Untersuch. Nahr. u. Genussmittel, 6 (1903), No. 6, p. 286*).—The eighth edition of this useful publication.

Composition and food value of the principal vegetables, BALLAND (*Rev. Internat. Falsif., 14 (1901), No. 3, pp. 76-78*).—The food value of vegetables is discussed and a table given showing the composition of a large number.

A study of the food value of some of the edible fungi of Ames, J. B. WEEMS and ALICE W. HESS (*Proc. Soc. Prom. Agr. Sci. 1902, pp. 165-172*).—Analyses are reported of a number of samples of mushrooms, including *Coprinus atramentarius*, *C. micaceus*, *Hirneola auricula*, *Hydnum coralloides*, *Morchella esculenta*, *Lycoperdon giganteum*, *L. Gemmatum*, *Pleurotus sapidus*, *P. ulmarius*, and cultivated mushrooms, *Agaricus campestris*, including local-grown specimens and French canned goods. The food value of mushrooms is discussed and the fact pointed out that although they are not superior and possibly not equal to ordinary vegetables in this respect, they deserve high rank as condiments and relishes and are of value in adding to the attractiveness of the diet.

Bread making from the standpoint of public health, A. LAURENT (*Compt. Rend. 10. Cong. Internat. Hyg. et Démogr., Paris, 1900, pp. 181, 182*).—Suggestions regarding the manufacture of wholesome bread.

The determination of the baking quality of flour by means of the gliadimeter, E. FLEURENT (*Ann. Chim. Analyt., 8 (1903), pp. 6-9; abs. in Chem. Centbl., 1903, I, No. 9, p. 542*).—It is stated that the baking quality of flour may be rapidly determined by the gliadimeter, an instrument devised by the author.

Concerning the identification of currant jam, J. SCHINDLER (*Ztschr. Landw. Versuchsw. Oesterr., 6 (1903), No. 1, pp. 22-26, figs. 2*).—Data are given regarding the chemical and microscopical examination of currant jam.

Antiseptics and their use in the preservation of food, S. C. PRESCOTT (*Tech. Quart.*, 15 (1902), No. 4, pp. 335-342).—Much matter regarding methods of preserving foods, condiments, and beverages is summarized and the use of preservatives from the standpoint of hygiene is discussed.

Are antiseptics occurring in preserved foods harmful and should their use be prevented? F. BORDAS (*Compt. Rend. 10. Cong. Internat. Hyg. et Démogr.*, Paris, 1900, pp. 109-120).—In a paper presented before the International Congress of Hygiene, Paris, 1900, the author considers the preservatives commonly used. The paper is followed by a discussion.

The preservation of meat, L. VAILLARD (*Compt. Rend. 10. Cong. Internat. Hyg. et Démogr.*, Paris, 1900, pp. 99-108).—A report with discussion presented before the International Congress of Hygiene, Paris, 1900.

The cleavage of gelatin, P. A. LEVENE (*Ztschr. Physiol. Chem.*, 37 (1902), No. 2, pp. 81-85).—Experiments are reported on the cleavage of gelatin by a number of digestive ferments. The resulting products were studied.

The influence of alcohol on the metabolism of protein, R. ROSEMAN (*Arch. Physiol. [Pflüger]*, 94 (1903), No. 11-12, pp. 557-592).—A critical discussion of recently published experiments.

Hydrolysis of fats and oils by means of dilute acids, and some notes on fat-splitting enzymes, J. LEWKOWITSCH (*Jour. Soc. Chem. Ind.*, 22 (1903), No. 2, pp. 67-70).—Experiments are reported in which attempts were made to hydrolyse animal and vegetable fats with hydrochloric acid, as well as tests in which lard was treated with this acid, and zinc dust, and other substances which it was believed would increase the efficiency of the acid, as the reaction seemed to be catalytic. Data are also given regarding the saponification of fat with ferments. A considerable amount of fat was hydrolysed by the acid, the portion varying with the different materials and under the experimental conditions. The substances added to the acid did not increase its effectiveness. The paper is followed by a discussion.

Experiment on the excretion of carbon dioxide during static and negative muscular work, J. E. JOHANSSON and G. KORÆN (*Skand. Arch. Physiol.*, 13 (1902), No. 3-5, pp. 229-250, figs. 2).—Using the apparatus and methods noted in a previous report (*E. S. R.*, 14, p. 789), a number of experiments are reported with man in which the respiratory quotient was determined when static and negative muscular work were performed. The former term the authors apply to work with the ergometer of such a nature that the external work was equivalent to zero. According to the authors in the case of static and muscular work, the carbon dioxide excreted is proportional within limits to the duration of muscular contraction. These and other deductions are discussed in detail.

ANIMAL PRODUCTION.

The feeding value and digestibility of alfalfa, H. SNYDER and J. A. HUMMEL (*Minnesota Sta. Bul.* 80, pp. 172-178, 180, figs. 2).—On the basis of composition the feeding value of alfalfa hay as compared with red clover hay is discussed, and experiments with 2 steers are reported on the digestibility of green alfalfa and alfalfa hay fed alone and with other materials, including a commercial stock food. The experiments were made by the usual methods, specially constructed stalls being used which facilitated the collection of solid and liquid excreta, the feeding being supervised by G. Craig. The average results of the digestion experiments follow, in every case the results given being the average of 2 tests:

Average coefficients of digestibility of alfalfa—Experiments with steers.

	Dry matter.	Protein.	Ether extract.	Nitrogen-free extract.	Crude fiber.	Ash.	Energy of digestible material.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Alfalfa hay, 16 lbs., nearly	65.84	75.38	55.88	71.86	57.57	51.40	64.41
Alfalfa hay, 16 lbs.; corn meal, 5 lbs.	70.98	83.63	60.82	73.44	63.29	64.84	70.09
Alfalfa hay, 16 lbs.; corn meal, 5 lbs., and 2 tablespoonfuls International Stock Food ...	60.70	67.59	27.64	72.42	49.57	49.83	61.20
Green alfalfa, third cutting, 42 lbs.	60.62	74.05	38.42	71.73	42.41	40.00	62.81
Alfalfa hay, 16 lbs.; barley meal, 5 lbs., and mangels, 15 lbs.	63.57	76.23	53.37	72.02	49.02	62.43	60.51

"Alfalfa hay is equal in digestibility to red clover. It is more digestible when fed with corn or barley meal than when fed alone. . . . When fed green, alfalfa shows a slightly lower digestibility than when fed as dry hay. This is probably due to the more laxative effect of the green food, which gives the digestive fluids less time to act on the food. A comparison of the two trials of the digestibility of alfalfa hay when fed with corn meal with the addition of a condimental food in one case, shows a remarkable difference in favor of the ration without the condimental food."

In the experiment with green alfalfa, according to the authors, the liquid and solid excreta contain 94 per cent of the nitrogen of the food, nearly 75 per cent of this quantity being contained in the urine. The fertilizing value of alfalfa is briefly discussed.

The digestibility of hog millet, H. SNYDER and J. A. HUMMEL (*Minnesota Sta. Bul. 80, pp. 178-180*).—The digestibility of hog-millet seed, ground and fed with water, was tested with a pig weighing about 180 lbs., the details of the experiment being attended to by C. P. Taylor. The test covered 17 meals, both the liquid and solid excreta being collected, the feces being marked with charcoal according to the method commonly followed in experiments with man. The following coefficients of digestibility were obtained: Dry matter 72.75, protein 68.36, ether extract 58.86, nitrogen-free extract 91.56, crude fiber 33.36, and ash 19.17 per cent. The available energy was calculated to be 70.60 per cent. The feed contained 0.905 lb. nitrogen, the urine 0.48 lb., and the feces 0.29 lb. Therefore, there was a gain of 0.14 lb., equivalent to 0.88 lb. of protein. During the test the pig gained 10 lbs. in weight.

According to the authors, the experiment indicates that hog-millet seed is equal in digestibility to barley, wheat, and shorts, but is not as digestible as corn meal or oil meal.

The available energy of timothy hay, H. P. ARMSBY and J. A. FRIS (Proc. Soc. Prom. Agr. Sci. 1902, pp. 96-109, *dgm. 1*).—Cooperating with the Bureau of Animal Industry of this Department respiration calorimeter experiments were made at the Pennsylvania Station with steers. The author briefly discusses some of the results obtained when timothy hay was fed with especial reference to what he terms the metabolizable energy—that is, the energy of the food minus the energy of excreta. The tentative conclusions follow:

"The nutritive value of timothy hay, either for maintenance or production, was not measured by its metabolizable energy, but was in every case materially less. In other words, the digestible nutrients of the hay did not replace body tissue in isodynamic proportions. The work of digestion and assimilation in the case of timothy hay appears to be so great that at, or even below, the maintenance requirement the heat production of the animal is in excess of the amount needed for the maintenance of body temperature.

"The availability of the metabolizable energy of timothy hay, within the range of these experiments, appears to be a linear function of its amount. The experiments afford no clear indication that the availability is less above than below the maintenance requirement."

Combustible gases escaping from an animal, J. A. FRIES (*Proc. Soc. Prom. Agr. Sci.* 1902, pp. 110-118).—In connection with respiration calorimeter experiments with steers, which are being carried on at the Pennsylvania Experiment Station, the author determined the amount of methane in a current of air drawn through the respiration chamber by passing an aliquot portion of this current through absorbers containing sulphuric acid and soda lime to remove water and carbon dioxide, and then through a copper tube filled with platinized kaolin, and heated to a dull red, and finally through other absorbers, which collected the water and carbon dioxide formed by the combustion of the methane. It was found that when the steer received 4,500 gm. of hay daily, the methane carbon was equal to 6.14 per cent of the total carbon. When 5,750 gm. of hay were fed the percentage was 6.09, but when the ration was reduced to 3,250 gm. the percentage was only 5.74, and when the hay was increased to 7,000 gm. the percentage was 7.63, the average of all these values being 6.399 per cent. Tests were also made to determine the amount of combustible gases ordinarily present in the atmosphere. The amount found was very minute, and according to the author it may be justly claimed that the atmosphere does not contain free hydrogen as a universal constituent to the amount of 19.5 cc. in 100 liters of air reduced to 0° and 7.60 mm. The quantity is said to be much smaller and to be variable, at times being either entirely absent or present only in the faintest trace.

Cotton-seed meal vs. decorticated cotton cake, T. WINTER (*Bd. Agr. [London] Rpt. Agr. Education and Research, 1901-2, pp. 51, 52*).—The comparative value of cotton-seed meal and decorticated cotton-seed cake as part of a ration was tested at the University College of North Wales with 2 lots containing 3 Welsh steers each, the basal ration consisting of 4 lbs. maize meal, 70 lbs. pulped swedes, 10 lbs. hay and straw chaff, and 5 lbs. long hay per head daily. In addition the steers in lot 1 were given 4 lbs. of cotton-seed meal and those in lot 2 an equal amount of decorticated cotton-seed cake, the amounts being after a time increased to 10 lbs. The average weight of the steers at the beginning of the test was about 1,120 lbs. and during the 77 days of the test the average daily gain per head in the 2 lots was 1.62 and 2.24 lbs. It was calculated that the gains made by lot 2 gave a net profit of \$3.10 per head in excess of those made by lot 1. From this and earlier work^a it would appear that "although there is not much difference between the market prices of these 2 feeding stuffs, the feeding value of decorticated cotton cake is altogether higher than that of cotton-seed meal."

Cattle-feeding experiment (*Jour. Bd. Agr. [London], 9 (1902), No. 2, pp. 227, 228*).—This test of decorticated and undecorticated cotton-seed cake was noted from another publication (see above.)

Substitutes for cream in skim milk as calf food (*Agr. Gaz. New South Wales, 13 (1902), No. 12, p. 1247*).—Crushed linseed or linseed meal is recommended as the best material for supplementing skim milk in calf feeding. The use of cocoanut-oil cake and other materials is also spoken of briefly.

Feeding experiments with calves (*Ber. Norges Landbr. Høiskoles Virks., 1901-2, pp. 188-190*).—An experiment was made with "Calf Cream," a food placed on the market by a Dutch firm.—F. W. WOLL.

Experiments in sheep husbandry, T. SHAW (*Minnesota Sta. Bul. 78, pp. 71-87*).—For the last 6 years tests have been carried on at the station to determine whether

^aBd. Agr. [London], Rpt. Agr. Education and Research, 1900-1901, p. 47.

the breeding habit of ewes could be so modified that lambs would be produced at a season most profitable for market. The conclusions drawn follow:

"The breeding habit in ewes which usually drop lambs in the spring may be so changed that they will produce them in the fall and early winter. This change can be effected sufficiently for practical uses in from two to three generations of judicious crossing when accompanied by a judicious selection. It may be effected thus quickly by choosing very common ewes of mixed breeding, and mating them with pure-bred Dorset rams, always reserving the earlier dropped lambs for breeding uses. In the transforming process the dams which have suckled winter lambs may usually be bred more readily before being turned out on grass than subsequently, and especially when fed a stimulating grain portion while yet in the sheds. When the change sought has been thus effected in the dams, a superior quality in the lambs may be obtained by using rams in service of certain of the dark-faced types and more especially of the Southdown and Shropshire breeds. Such foods as clover hay, and corn fodder, bran, oats, barley, corn and oil cake, also field roots prove very satisfactory under Minnesota conditions for the production of such mutton in winter. In the markets of the West the demand for such lambs is not yet so good relatively as in certain markets further East."

In earlier experiments at the station the importance to the sheep industry of specially sown pastures has been demonstrated. A test, beginning in May and covering 112 days, was undertaken to learn the value of feeding grain to wethers thus pastured, the crops grazed including winter rye, peas and oats, barley and oats, rape and kale, rape, and peas and oats in succession.

On pasturage alone a lot of 10 wethers weighing about 80 lbs. each made an average gain of 16.8 lbs. per head. When the same number were fed 0.5 lb. of oats per head per day in addition to pasturage, the corresponding gain was 26.9 lbs. After the close of the experiment proper the feeding was continued for 77 days, both lots being given 0.5 lb. grain per head per day. For a month the sheep were pastured on cabbage and later on rape. The lot which received grain during the supplementary test only gained an average of 28 lbs. per head, the lot which had received grain from the start, 34.1 lbs. per head. Definite conclusions regarding the cost of the gain were not drawn, but the author believes that in general "feeding a small grain supplement of oats to wethers that are being grazed is profitable for a period of several months, after which it becomes less profitable, if, indeed profitable to any extent."

Sheep-feeding experiments at Newton Rigg, T. H. MIDDLETON (*Bd. Agr. [London], Rpt. Agr. Education and Research, 1901-2, pp. 72, 73*).—The comparative merits of mixtures of equal amounts of decorticated cotton-seed cake and corn, linseed cake and oats, and linseed cake and corn fed in addition to Swedish turnips and hay was tested with 3 lots, each containing 16 cross-bred sheep, by the Durham College of Science at Newton Rigg. Practically the same amount of the different feeding stuffs was consumed by the 3 lots in the 54 days of the trial. The lots weighed on an average not far from 1,568, 1,531, and 1,552 lbs., respectively, at the beginning of the trial, the average daily gains per head being 1.21, 1.08, and 1.32 lbs. The greatest profit, \$1.68, was obtained with lot 3. According to the author "oats appear to have given a better result than maize; there appears to have been but little difference in the values of cotton and linseed cakes, and no advantage in increasing the maize during the latter stage of the fattening."

Sheep-feeding experiment (*Jour. Bd. Agr. [London], 9 (1902), No. 2, pp. 224, 225*).—Noted from another publication (see above.)

The improvement of pasture at Hatley as tested by the effects on sheep, T. B. WOOD (*Bd. Agr. [London], Rpt. Agr. Education and Research, 1901-2, pp. 75-77*).—A brief note on the Cambridge University experiments (1901) on the effects of different manures on pasture as shown by the gains made by sheep. In 5 months

the greatest gain, averaging 2.49 lbs. per sheep per week, was made on a pasture which had been manured with 0.5 ton basic slag in 1900 and nothing since. The smallest gain, 1.35 lbs. per head per week, was made by sheep pastured on an unmanured plat.

Three types of market sheep, W. L. CARLYLE (*Wisconsin Sta. Rpt. 1902, pp. 72-74, pl. 1*).—On the basis of data derived from an examination of the carcasses of 2 sheep of good type fed generously and 1 fed poorly, marked advantages are pointed out for the former method.

The comparative value and effect upon the lambs of feeding various grain rations to pregnant ewes, W. L. CARLYLE and T. F. McCONNELL (*Wisconsin Sta. Rpt. 1902, pp. 62-71*).—The effect of different grain rations on ewes and their young was studied, dried brewers' grains being found the cheapest, with bran, shelled corn, and oats following in the order named, all the grains being fed at the rate of 0.5 lb. per head per day.

The authors' conclusions were in effect as follows: Any of the grain rations when fed in connection with 2.5 lbs. of corn silage and 2 lbs. mixed hay per ewe per day was quite satisfactory so far as the physical condition of the ewes was concerned. The results would seem to indicate that the ewes fed the rations containing the largest amount of protein drank the largest amount of water.

When the milk supply of the ewes at parturition is considered, it appears that the dried brewers' grains produced by far the best results. Taking into consideration the size and strength of the lambs at birth, it appears that the ration of whole oats and that of dried brewers' grains produced the strongest and heaviest lambs, with the results slightly in favor of the former.

Corn silage in connection with hay continues to meet with approval as a coarse fodder ration for pregnant ewes in winter. To arrive at more definite results along this line it would be better to have the experimental feeding period extend over a greater portion of the time that the young lamb is dependent upon its dam for existence.

Some observations on sheep breeding from the experiment station flock records, W. L. CARLYLE and T. F. McCONNELL (*Wisconsin Sta. Rpt. 1902, pp. 42-61, chart 1*).—Noted from another publication (E. S. R., 14, p. 685).

Experiments in sheep breeding, T. WINTER (*Bd. Agr. [London], Rpt. Agr. Education and Research, 1901-2, pp. 53-56*).—In the first of 2 tests made at the University College of North Wales, 3 lots containing respectively 30, 20, and 25 small mountain ewes, were bred respectively with a Wiltshire, Shropshire, and Southdown ram. Twenty-nine living lambs were dropped by the ewes in the first lot, 18 by those in the second lot, and 25 by those in the third. Part of these were sold for slaughter when 4 or 5 months old, the remainder a month later, the average weight of the lambs in the 3 lots when sold being 68, 68, and 67 lbs., respectively.

In the second test 4 lots of 15 ewes each and 1 of 21 ewes, in every case large animals, were used. These lots were bred respectively with Border-Leicester, Shropshire, Oxford, Wiltshire, and Suffolk rams, the lambs dropped being 21, 28, 19, 20, and 30, respectively. The lambs were sold when ready for market. Taking into account the number of early and late sales and other data, the conclusion was drawn that the Suffolk cross gave the best results.

Grazing and feeding experiments with pigs, J. F. DUGGAR (*Alabama College Sta. Bul. 122, pp. 48*).—The principal object of these tests, which extended over 4 years, was to ascertain the relative pork producing value of some of the hog crops of special importance in the South and to study their effect on the quality of flesh and lard, that portion of the investigation, which treated of forage crops being a continuation of work previously reported (E. S. R., 10, p. 577).

To study the relative gains made before and after weaning, a sow and litter of 7 pigs about 1 month old were hurdled on vetch and turf oats and fed some corn in

addition for 5 weeks when the sow was removed and the feeding continued with the pigs 3 weeks longer. The latter made an average gain of 22.7 lbs. per week before weaning and 18.5 lbs. after, the area grazed over by the sow and pigs being about 1,710 sq. ft. per week before and 1,286 sq. ft. after weaning. The corn meal eaten per pound of gain was equivalent to 4.88 lbs. before and 4.4 lbs. after weaning. The sow lost nearly 20 lbs. in weight. The unsatisfactory rate of growth is attributed in part to insufficient shade.

Other forage crops tested included Spanish peanuts, chufas, cowpeas, sweet potatoes, sorghum, and spring-sown and fall-sown Dwarf Essex rape. When hurdled on spring-sown Dwarf Essex rape and fed corn in addition the 7 pigs mentioned above gained 103 lbs. in 28 days beginning May 27, requiring 3.1 lbs. of corn meal and the rape from 40.5 sq. ft. per pound of gain. On fall-sown rape 4 pigs gained 263 lbs. in 102 days beginning January 6, requiring 2.5 to 2.9 lbs. of corn per pound of gain in addition to the green feed. During a part of the time they were hurdled on second-growth rape. Assuming that 5 lbs. of corn meal alone is required per pound of gain the author calculates that on an average 1 acre of rape will produce 452 lbs. of pork, worth \$22.50.

Seven young pigs used in one of the above tests were grazed on sorghum from June 24 to September 2 and fed in addition 1.5 lbs. of ground cowpeas and corn 1:1 per head daily, and gained 224.4 lbs., equivalent to 635 lbs. per acre of sorghum. The author believes, where labor is cheap or where a corn harvester can be used, that it will be more profitable and more economical to feed sorghum to the pigs than to graze them on it.

Sorghum pasturage in the dough and ripening stages fed with grain or with Spanish peanuts was compared with grain alone and with ripe cowpea pasturage. The grain mixture consisted of corn meal and cowpea meal 2:1. The test covered 5 weeks, sorghum being found of little value, effecting a saving of only 12 per cent of the grain required for a pound of gain. The gains on sorghum and peanuts were unsatisfactory, and the waste was very large with the cowpeas. The lot on grain alone made a very satisfactory growth, producing a pound of gain on 3.74 lbs. of the grain mixture. On an average the author calculates that the sorghum produced 174 lbs. of pork per acre, worth \$8.70.

Seven tests with Spanish peanuts are reported, in 6 of which the pigs were penned or hurdled on the peanuts and harvested the crop. In the other pulled peanuts were fed. In 4 tests the forage crop was supplemented by corn meal, and in one by corn meal and skim milk. On corn meal and peanuts the calculated gains due to the peanuts alone ranged from 225 lbs. to 247 lbs. per acre. On skim milk and corn meal the gain attributed to peanuts alone made by a sow and 9 pigs was 432 lbs. per acre. On peanuts alone very small pigs (averaging 28.1 lbs. in weight) made gains equivalent to 503 lbs. per acre.

The gains made in 18 days by lots of 3 pigs each on peanuts and chufas, each fed with a half grain ration, were practically equal (79 and 81 lbs., respectively) and were greater than on a full grain ration (70.5 lbs.). A similar lot grazed on Spanish peanuts without grain gained only 22 lbs. From all the tests of peanuts with grain the author concludes that this crop will produce 333 lbs. of pork per acre, valued at \$16.65. In 2 tests peanuts alone produced per acre 281 lbs. of pork, worth \$14.05.

In another test young pigs hurdled on chufas and fed a little corn and cowpea meal gained at the rate of 660 lbs. per acre of chufas in addition to 1,429 lbs. of grain. Averaging the results of the 2 tests with chufas the author calculates that an acre would produce 307 lbs. of pork worth \$15.35.

For 35 days, beginning in November, 2 pigs were pastured on sweet potatoes and also fed per head daily a half ration (3 lbs.) of ground corn and cowpeas 2:1. The total gains amounted to 67 lbs. The sweet potatoes were not eaten with relish and some were rooted up and wasted. The author believes feeding less grain would have

diminished the waste but considers it always advisable to feed a little nitrogenous material as cowpeas, peanuts, etc., with sweet potatoes.

Summarizing his results the author states that an acre of the best of the forage crops tested, namely, peanuts, rape, and chufas, would afford pasturage for 1 month for 25 pigs averaging 100 lbs. in weight, when a half ration of grain was fed in addition. The average amount of grain required per pound of gain in addition to the forage crops tested was as follows: 1.77 lbs. with peanuts, 2.30 lbs. with chufas, 3.07 lbs. with cowpeas, 2.68 lbs. with rape, 3.70 lbs. with sorghum, and 3.13 lbs. with sweet potatoes. From the results of this and previous work at the station covering all told a period of 7 years the author suggests the following succession of forage crops for pigs: Fall-sown rape and chufas, January and February; fall-sown rape, vetch and oats, rye, wheat, etc., March to April 15; vetch and oats, crimson clover, oats and wheat, April; spring-sown rape, vetch and oats, wheat and the usual pasturage, May; spring rape, stubble fields, turf oats, and the usual pasturage, June; sorghum, early varieties of cowpeas, and the usual pasturage, July and August; Spanish peanuts, cowpeas, sweet potatoes, and sorghum, September to November; and chufas and fall-sown rape, December.

Four tests on the effects of cotton-seed meal as part of the ration are reported in detail. A summary of this work follows: When fed corn meal with 20 or 25 per cent cotton-seed meal shoats ate but little and made a very slow growth in most of the tests. "In other experiments they required only 3.84 and 4.68 lbs. of this mixture per pound of growth. . . . Calculated on a basis of 100 lbs. live weight, daily doses of 0.25, 0.40, 0.41 and 0.53 lb. of cotton-seed meal for 34 to 38 days caused sickness or death; 0.61 lb. daily for 35 days fed in different years to shoats of practically the same size caused evident unthrift in one experiment, while in the other no immediate effects were discernible. Shoats averaging 143 lbs. in weight were not hurt by eating for 31 days 0.73 lb. of cotton-seed meal daily per 100 lbs. live weight. Evidently the younger the pig, the more susceptible they are to cotton-seed meal poisoning.

"The health of shoats was injuriously affected or death resulted where, in an exclusive mixed grain ration, the amount of cotton-seed meal consumed per 100 lbs. of live weight reached, with the smallest shoats 9.2 lbs., and with larger shoats 21.4 lbs.; while in a third experiment 21.5 lbs. of cotton-seed meal was consumed per hundredweight without immediate evidences of injury, and in a fourth experiment 22.6 lbs. per 100 lbs. of live weight was consumed without visible effects on the health of large shoats. Where a cotton-seed meal mixture was fed in connection with grazed sorghum, cut sorghum, or grazed peanuts, toxic effects were manifested when respectively 21.6, 18.9, and 17.7 lbs. of cotton-seed meal per hundredweight had been consumed. We obtained highly satisfactory growth when some cotton-seed meal was fed for short periods to shoats while grazing peanuts."

Corn hearts, cowpea meal, and corn bran were compared when fed with equal amounts of rice bran in a test made with 3 lots of 3 pigs each, covering 7 weeks. The feed required per pound of gain was 7.38 lbs. on the corn-heart mixture, 5.95 on the cowpea meal, and 5.5 on the corn-meal ration. In the opinion of the author corn hearts proved decidedly inferior to corn meal and to cowpea meal. Analyses showed that the rice bran used contained 9 per cent protein, and the corn hearts 8.9 per cent.

Several tests are reported in which rice polish was compared with corn and mixed grains, with skim milk, and with corn with and without skim milk. In 1 test the value of different proportions of the rice polish was also taken into account. On an average a pound of gain required 3.73 lbs. of rice polish as compared with 4.74 lbs. corn meal. At this rate 78.6 lbs. of the former was equal to 100 lbs. of the latter, i. e., feeding rice polish effected a saving of 21.4 per cent.

In some of the above tests skim milk formed a part of the ration. In the author's opinion this feeding stuff supplied in moderate amounts effected a saving of about half the grain ordinarily fed.

The effect of the different feeds on the firmness of lard was likewise studied, the results being recorded in detail. Peanuts fed until the pigs were slaughtered caused very soft lard. Chufas had nearly as pronounced an effect. The supplementary feeding of any of the grains tested increased markedly the hardness of the lard, but it is said that feeding grain exclusively for 26 to 35 days just before slaughtering failed to make the flesh and lard as firm as that of pigs which had never been fed peanuts. When 20 or 25 per cent cotton-seed meal was fed in addition to corn meal the melting point of lard was 3.4° F. higher than on corn meal alone.

With several of the pigs the effect of cotton-seed meal and corn meal and of corn meal alone on the weight of the internal organs, the blood, and the dressed carcass was also studied.

"The most significant differences attributable to the foods are the greater weight of kidneys and heart of the pigs receiving the more nitrogenous ration, and the greater weight of lungs (as in our former experiments) when the ration was highly carbonaceous."

Whole corn compared with corn meal for fattening pigs, W. A. HENRY (*Wisconsin Sta. Rpt. 1902, pp. 10-16*).—Using younger pigs than in previous tests (E. S. R., 13, p. 980) the relative value of whole corn and corn meal, each fed with an equal quantity of wheat middlings, was studied. In the first trial, which was made with 4 lots of 3 razorback or razorback crosses, weighing not far from 75 lbs. each, 2 lots on whole corn gained 234 and 169 lbs., respectively, in the 12 weeks of the trial, consuming 4.44 and 5.94 lbs. of whole corn per pound of gain. The 2 lots on corn meal gained respectively 218 and 166 lbs., consuming 4.49 and 5.79 lbs. of corn meal per pound of gain.

The second trial covered 13 weeks and was made with 2 lots of 1 Berkshire and 2 Poland-China pigs each, weighing about 133 lbs. per head at the beginning of the trial. On whole corn the total gain was 255 lbs., the corn eaten per pound of gain being 5.59 lbs. On corn meal the total gain was 274 lbs. and the amount eaten per pound of gain 5.13 lbs.

Summarizing the results of the tests at the station, which have extended over 7 years, the author states that a saving due to grinding has been observed in 9 cases, the amount saved ranging from 3 to 17.6 per cent. In 3 cases a loss ranging from 1 to 9 per cent has been observed. No allowance has been made for the cost of grinding, "the figures given being based entirely upon the gain or loss incurred while feeding."

Results of an experiment to determine the comparative effect upon the growth, development, and character of the carcass of pigs fed upon rations of ground peas and corn meal, W. L. CARLYLE and T. F. MCCONNELL (*Wisconsin Sta. Rpt. 1902, pp. 17-33, figs. 1,2*).—The comparative value of ground peas and corn meal was studied in continuation of earlier work (E. S. R., 13, p. 979) with 2 lots, each containing 7 pigs (Berkshire, Poland-China, razorback, and razorback crosses), averaging about 68 lbs. in weight at the beginning of the trial. During the test, which covered 28 weeks, 1 of the pigs fed ground peas died. Each of the grains was made into a slop with water and fed ad libitum 3 times a day. The nutritive ratio of the pea meal ration was 1:3.2 and that of the corn meal ration 1:9.8. On the former the average daily gain per pig was 0.837 lb. and on the latter 0.540 lb., the feed eaten per pound of gain being 4.95 lbs. and 6.06 lbs., respectively. In connection with the test the different breeds were compared. The lowest daily gain per pig, 0.55 lb., was observed with the razorbacks, and the greatest gain, 0.75 lb., with lot showing 0.75 Berkshire and 0.25 razorback blood. The latter pigs and 2 other razorback-Berkshire crosses required the smallest amount of feed per pound of gain, namely, 5.2 lbs. The largest amount, 6.17 lbs., was required by the Poland-Chinas. The pigs were slaughtered and the weight of the blood, loose fat, and internal organs recorded. The dressed weight was practically the same in both lots, being about 77 per cent of the live weight.

"While the layer of fat on the outside of carcass is not greatly different in pigs fed peas from those fed corn, partly owing to the better appetites and greater growth and development of the pea-fed lot, yet the amount of lean meat or muscle is so small in the corn-fed lot that the difference in proportion of lean to fat in the different carcasses is readily discernible."

In the opinion of those judging the pigs, the quality of meat in the carcass of one of the pigs was thought to fairly represent all the corn-fed lot. In this "the fat was soft and flabby, almost blubbery to the touch, and the muscle was pale in color and appeared to lack tone."

Individual peculiarity, in the authors' opinion, was responsible for the wide variation observed in the amount and proportion of internal or loose fat in the different pigs.

The results of a feeding trial comparing razorback with cross-bred razorback and improved breeds of hogs, W. L. CARLYLE (Wisconsin Sta. Rpt. 1902, pp. 33-41, figs. 4).—The relative gains made during the 11 weeks of the trial by pure-bred razorback pigs and crosses was tested with 4 lots of 3 pigs each, lot 1 containing razorbacks of the first generation; lot 2, razorbacks of the second generation; lot 3, razorback-Poland-Chinas, and lot 4, razorback-Berkshires. The pigs weighed about 150 lbs. each at the beginning of the test.

All the lots were fed ad libitum a mixture of equal parts of ground corn, ground rye, and shorts. At the end of 4 weeks skim milk was added to the ration, the amount being on an average approximately 1.4 lbs. of milk to a pound of grain. It was noticed that the razorback pigs especially were exceedingly variable in their appetites, frequently gorging themselves, then eating sparingly for several feeds, and then gorging again. The total gain made by the razorbacks of the first generation was 196 lbs., by those of the second generation 266 lbs., by the Poland-China crosses 346 lbs., and by the Berkshire crosses 358 lbs.

Considering the test as a whole the average daily gain per pig was 1.02 lbs. with the razorbacks and 1.52 lbs. with the cross-bred pigs, the former requiring 4.2 lbs. of grain and 5.65 lbs. of skim milk per pound of gain, and the latter 3.66 and 5.30 lbs., respectively. The importance of adding skim milk to the ration is shown by the fact that while grain only was fed the amount required per pound of gain by the razorbacks was 6.24 lbs. and by the cross-bred pigs 5.66 lbs. After skim milk was added to the ration the amounts were 3.64 and 3.31 lbs. Although definite conclusions were not drawn, as the experiments will be continued, it will be noted that larger gains were made by the improved stock, and that the second generation razorbacks gained more than the first. This is a matter of interest, since it is one of the purposes of the experiments which are being carried on at the station to determine the extent to which liberal feeding and suitable shelter will improve such pigs in successive generations.

Horse feeding, H. WIBBENS (Cultura, 14 (1902), No. 173, pp. 520-524).—Horse feeding in the province of Groningen, Holland, is discussed with especial reference to the use of molasses.

Establishment of agencies by the Indian Government in Australia for the purchase of horses for military purposes, A. BRUCE (Agr. Gaz. New South Wales, 13 (1902), No. 12, pp. 1178-1181).—Reasons for the desirability of the establishment of government agencies for the purchase of Australian horses for remounts are given.

Suggestions offered by the Indian Horse and Mule Breeding Commission to Australian breeders, A. BRUCE (Agr. Gaz. New South Wales, 13 (1902), No. 12, pp. 1174-1178, pl. 1).—The kind of horses required for remounts in India are discussed and suggestions given for raising Australian horses and mules of suitable character.

Mules at the Hawkesbury College farm, H. W. PORRIS (Agr. Gaz. New South Wales, 13 (1902), No. 12, pp. 1222-1226, figs. 3).—The experience at the Hawkesbury Agricultural College was favorable to the use of mules for farm work.

Sugar mules, H. D'ANCHALD (*Jour. Agr. Prat., n. ser., 5 (1903), No. 5, pp. 152, 153*).—A brief note on the successful feeding of molasses to mules in Louisiana.

Concerning the feeding value of hay from irrigated meadows, F. TANGLE (*Londr. Vers. Stat., 57 (1902), No. 5-6, pp. 359-366*).—Sickness among horses on one of the government farms had been attributed to eating hay from irrigated meadows. Botanical and chemical analyses of such hay are reported. In experiments previously noted (*E. S. R., 14, p. 900*) this hay was fed and no bad effects were observed, although it was given the horses for some 6 months. It was found that the irrigated meadow hay contained very little calcium.

Poultry notes, J. BARCLAY (*Jour. Jamaica Agr. Soc., 7 (1903), No. 1, pp. 21, 22*).—The relative merits of different breeds of ducks are discussed with special reference to local conditions.

Egg and poultry raising at home, W. M. ELKINGTON (*New York: Charles Scribner's Sons, 1902, pp. 92, figs. 19*).—The choice of breeds, feeding, care of poultry houses, and related topics are treated of.

The peanut for poultry (*Agr. Gaz. New South Wales, 13 (1902), No. 12, p. 1173*).—Statements regarding the successful use of peanuts as a feed for poultry are quoted from the *Texas Stockman*. Regarding their use under local conditions it is said that "wherever peanuts (or earthnuts, as they are sometimes called) have been tried in New South Wales successful results have been reported. They are easily cultivated and the 'nuts,' which grow in a cluster underground, can be dug up and stored for a long time without much care, or fowls or pigs can be turned in to root out the crop for themselves."

Concerning the chemical composition and formation of goose fat, S. WEISER and A. ZATSCHEK (*Arch. Physiol. [Pflüger], 93 (1902), No. 3-4, pp. 128-133*).—As shown by chemical examination, fat of maize and of broom-corn seed differed quite markedly. Geese were fattened on these grains. Chemical examination showed that the body fat gained on the 2 grains was identical. The authors point out that the amount of fat present in the grains was so small that it would have served for the formation of only a small portion of the body fat and that nearly all must have been formed from carbohydrates.

A new departure in the science of fattening, R. WARINGTON (*Agr. Students' Gaz., n. ser., 11 (1902), No. 2, pp. 35-41*).—On the basis of O. Kellner's experiments (*E. S. R., 12, p. 1071*) the author discusses the true nutritive value of feeding stuffs as distinguished from the values shown by figures for composition and digestibility.

Analyses of fodders and feeding stuffs, W. O. ATWATER (*Connecticut Storrs Sta. Rpt. 1901, pp. 165-178*).—Analyses are reported of a number of feeding stuffs, including ensilage corn, corn and soy-bean ensilage, cured corn stover, oat hay, timothy hay, hay of mixed grasses, oat and pea hay, black grass hay, soy beans, corn, corn meal, corn-and-cob meal, gluten meal, cotton-seed meal, wheat bran, wheat middlings, brewers' grains, grain mixtures, and cereal breakfast food by-products.

Concentrated feeds, J. B. LINDSEY (*Massachusetts Sta. Bul. 85, pp. 32, fig. 1*).—Feeds, feeding standards, condimental feeds, and related topics are discussed and analyses made in accordance with the State law are reported of a number of samples of cotton-seed meal, linseed meal, gluten feed, distillers' grains, malt sprouts, wheat middlings, wheat bran, mixed feeds, corn meal, hominy meal, oat feed, corn and oat feeds, dairy and miscellaneous feeds, commercial poultry feeds, meat and bone meals, and meat scraps.

Licensed commercial feeding stuffs for 1902, F. W. WOLL and G. A. OLSON (*Wisconsin Sta. Rpt. 1902, pp. 250-258*).—A list of feeding stuffs licensed in the State is given and analyses, usually limited to determinations of protein and fat, reported, which were made of a number of feeding stuffs in accordance with the provisions of the State feeding stuff law. These included linseed meal, cotton-seed meal, gluten meals and feeds, germ oil meal, corn bran, hominy feeds, mixed commercial feeds

and breakfast food by-products, calf meal, dried grains, dried distillers' grains, germ middlings, granulated bone, blood meal, tankage, a chicken feed, wheat bran, middlings, shorts, and red dog flour. The authors state that, as a general rule chemical analysis and microscopic examination showed the wheat milling products to be of superior quality, and free from any adulteration, with the exception of the output of a few mills whose goods were found to contain admixtures of either ground or whole wheat screenings.

Ground mixed feeds are exempt from the provisions of the State feeding stuff law, but in order to determine whether such materials are true to name 96 samples were examined. Of these 33 were considered suspicious from the fact that they contained more than 7 per cent crude fiber. Eighteen samples were believed to be adulterated since they had a crude fiber content of 9 per cent or more. From these figures the authors conclude "that 38 per cent of the samples of corn and oats sampled and analyzed in our laboratory during the past season were suspicious, and 24 per cent were in all probability adulterated. . . . The materials used for adulterating corn and oat feeds are low-grade refuse products like oat hulls, oat dust, crushed corn-cobs, corn bran, and mixed corn and oat feeds composed largely of such refuse materials. . . . These adulterations, and the sale of mixed corn and oat feeds as pure ground grains, form the most serious violation of our State feeding stuff law. Other adulterations that have been established during the past season are the admixture of ground or whole screenings to mill refuse feeds, oat feeds, and ground corn and oats, and of . . . ground corn pith to dried brewers' grains. Aside from the adulteration of the grain feeds, the situation in this State is not, on the whole, discouraging."

Concentrated feeding stuffs licensed for sale in Wisconsin, 1903, F. W. WOLL (*Wisconsin Sta. Bul.* 99, pp. 3, 4, 6-8).—The text of the State feeding stuff law is given and also a list of the concentrated feeds licensed for sale in the State together with figures showing their guaranteed protein and fat content.

The Wisconsin feeding stuff law (*Wisconsin Sta. Rpt.* 1902, pp. 282-284).—The text of the State feeding stuff law is quoted.

Food for live stock (*Jour. Jamaica Agr. Soc.*, 6 (1902), No. 11, pp. 435-439).—The general principles of stock feeding are discussed and a number of rations made up of local feeding stuffs are suggested.

Barley chaff as a cattle feed, J. P. WAGNER (*Jour. Agr. Prot.*, n. ser., 5 (1903), No. 5, p. 153).—On the basis of the nutritive material contained barley bran is said to be worth 50 cts. per 100 kg. as a feeding stuff. Brief notes regarding its use are given.

The chemical composition of the bottle-tree, J. C. BRÜNNICH and W. MAXWELL (*Queensland Agr. Jour.*, 11 (1902), No. 5, pp. 363-365).—The pith of the bottle-tree (*Sterculia rupestris*) is suggested as a possible cattle feed in times of extreme drought. Proximates and ash analyses of this material are reported.

Concerning cacao shells, P. WELMANS (*Ztschr. Offentl. Chem.*, 7 (1901), pp. 491-500; *obs. in Ztschr. Untersuch. Nahr. u. Genussmitl.*, 5 (1902), No. 23, pp. 1165-1168).—A study of cacao shells with especial reference to the detection of this material when in finely ground form and used as an adulterant for powdered cacao.

Copra products at Marseille, R. P. SKINNER (*U. S. Consular Rpts.*, 70 (1902), No. 267, pp. 531-534).—Considerable information is given regarding the manufacture of coconut butter and similar products made from coconut oil.

Crushed corncobs, F. B. GUTHRIE (*Agr. Gaz. New South Wales*, 13 (1902), No. 10, p. 1065).—The feeding value of ground corncobs is discussed and analyses of ground cobs and ground cob mixtures are given.

Effects of discriminate ringbarking, and the value of Kurrajong as a fodder tree, W. MACDONALD (*Agr. Gaz. New South Wales*, 13 (1902), No. 2, pp. 1102-1104).—The value of Kurrajong scrub (*Sterculia diversifolia*) for feeding purposes is discussed.

Molassecuit (*Louisiana Planter*, 29 (1902), No. 1, p. 3).—It is stated that this stock feed consists of 80 per cent molasses and 20 per cent of the fine cellular matter

of sugar cane secured from bagasse. It is claimed that this material is dry and has an advantage over molasses, since it can be readily handled and shipped.

Variation in the composition of molasses feeds; composition and feeding value of brewers' grains, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 5* (1903), pp. 37, 38).—The author quotes and discusses the composition of a number of such feeding stuffs.

Poppies and poppy-seed cake, F. MACH (*Landw. Vers. Stat., 57* (1902), No. 5-6, pp. 419-459, pls. 3).—The culture of poppies and the composition and feeding value of poppy seed and poppy-seed cake are discussed and proximate and ash analyses are reported. The author summarizes the results obtained by many previous investigators.

Sugar cane as a fodder for stock, F. B. GUTHRIE (*Agr. Gaz. New South Wales, 13* (1902), No. 10, p. 1054).—Analyses are reported of whole sugar cane, sugar-cane tops, and a mixture of equal parts of the two. These analyses follow:

Analyses of sugar-cane feeding stuffs.

	Water.	Protein.	Fat.	Nitrogen-free extract.	Crude fiber.	Ash.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Whole sugar cane.....	71.0	0.6	0.4	18.0	9.5	0.5
Sugar-cane tops.....	75.2	1.7	.6	13.6	7.4	1.5
Whole cane and tops 1:1.....	73.1	1.1	.5	15.8	8.5	1.0

On the protein compounds in whale-flesh meal, A. KAVLI (*Norsk Landmandsblad, 21* (1902), No. 24, pp. 281, 282).—Analyses of 24 samples.

Succus entericus and pancreatic digestion, E. POZERSKI (*Thesis, Paris, 1902; abs. in British Med. Jour., 1902, No. 2179, Epit., p. 52*).—From experiments with rabbits and dogs the following conclusions regarding the effect of the intestinal juice upon the amylolytic action of the pancreatic and salivary secretions were drawn: "There exists in the succus entericus a substance which renders active (or aids the action of) the amylase ferment of the pancreatic secretion. This substance has a similar adjuvant action on the amylase of the saliva and of *Aspergillus niger*. Maceration of lymphoid glands, especially the mesenteric glands and spleen, and of leucocytes gives rise to a substance which has similar activity in aiding the amylolytic ferment of the pancreatic juice. This substance has nothing in common with the trypsin of the pancreatic juice. It is not itself a diastatic ferment. The adjuvant action of this substance is probably due to the presence in it of certain salts and proteid materials, whose precise composition, however, has not yet been ascertained. This substance is present in the succus entericus; but as to its exact origin (whether secreted by the mucosa or derived from leucocytes which have passed into the alimentary canal in the processes of digestion) there is still some doubt."

Animal fluids and tissues in their physical relations. VI, Electrical conductivity and lowering of the freezing point as indicators of protein cleavage, M. OKER-BLOM (*Skand. Arch. Physiol., 13* (1902), No. 6, pp. 359-374).—Experiments are reported and discussed.

DAIRY FARMING—DAIRYING.

Investigation in milk production, T. L. HAECKER (*Minnesota Sta. Bul. 79, pp. 89-148*).—Several lines of work are reported as follows:

The food of maintenance (pp. 89-97).—This subject was studied in a preliminary test made in 1894 with 2 cows, in a second test made in 1896-97 with 2 cows, and in a third test made in 1897-98 with 3 cows. On an average daily ration of 11.38 lbs. of dry matter containing 0.63 lb. of digestible protein, 5.75 lbs. of carbohydrates, and

0.12 lb. of ether extract, dry, barren cows made an average daily gain of 0.23 lb. The deduction is made that a ration of 11.5 lbs. of dry matter containing 0.6 lb. of digestible protein, 6 lbs. of carbohydrates, and 0.1 lb. of ether extract is sufficient for maintenance of dry, barren cows at rest in stall. It is tentatively suggested that for cows at work in a dairy with ordinary good care and comfortable quarters the following allowance of digestible nutrients per 1,000 lbs. live weight be made for maintenance: Protein 0.7 lb., carbohydrates 7 lbs., and ether extract 0.1 lb., which is somewhat lower than the Wolff standard.

Nutrient requirements (pp. 98-112).—The experiments reported in Bulletin 71 of the station (E. S. R., 13, p. 683) and discussed with reference to protein requirements are here discussed with reference to the other nutrients as well. It is believed that the Lehmann factors for milk production prescribe more nutrients than are needed, that the quality of milk is quite as important a factor as the quantity of milk in formulating a feeding standard, and that heifers require more nutrients per pound of milk yielded than do mature cows. Tables are given which show the calculated nutrients in excess of that required for maintenance as given above used by mature cows and by heifers in the production of 1 lb. of milk testing a given percentage of fat, and the use of the tables is explained. Some of the figures are given in the following table:

Nutrients required by mature cows and by heifers for the production of one pound of milk.

	Mature cows.			Heifers.		
	Protein.	Carbo- hydrates.	Ether extract.	Protein.	Carbo- hydrates.	Ether extract.
Fat content of milk:	<i>Pound.</i>	<i>Pound.</i>	<i>Pound.</i>	<i>Pound.</i>	<i>Pound.</i>	<i>Pound.</i>
2.5 per cent	0.0862	0.164	0.0124	0.0880	0.188	0.0127
3 per cent0897	.181	.0136	.0443	.217	.0148

5.5 per cent0572	.263	.0194	.0755	.358	.0256
6 per cent0607	.280	.0206	.0818	.387	.0278

Protein requirements (pp. 113-127).—In a feeding experiment from November 11, 1901, to February 17, 1902, the following grain rations were fed to different lots of 6 cows each: (1) Equal parts of corn, bran, and gluten meal; (2) four parts each of corn and bran and one part of gluten meal; and (3) equal parts of corn, barley, and oats. The nutritive ratios were, respectively, 1:6.3, 1:7.7, and 1:9.7. Data for 8 consecutive weeks are given, from which the following conclusions in substance are drawn: "Rations having a nutritive ratio of 1:7.7 and 1:9.7, respectively, were as effective in the production of milk, butter fat, and milk solids as was the one having a nutritive ratio of 1:6.3. The protein required in milk production depends upon the quantity and quality of milk yielded. In the production of butter fat actually more but relatively less protein and other nutrients were required to a pound of butter fat with cows giving milk containing a high per cent of fat than with those giving milk containing a low per cent of fat. In the production of milk solids less nutrients were required to a pound with cows giving milk having a low per cent of butter fat than with cows giving milk having a higher per cent of fat."

Influence of stage of lactation on nutrient requirements (pp. 128-148).—Data are given showing the live weight, nutrients consumed, and milk, fat, and solids produced by each of 8 cows at different stages of lactation. Averages are also given for 15 cows during the first 9 weeks of lactation. The author makes the following deductions from the data presented:

"(1) During the early stages of the period of lactation cows lose rapidly in body weight—of 15 cows the average decrease per cow the first week was 49 lbs.—and during 56 days there was a daily average loss per cow of 2 lbs.

"(2) During the time when the decrease in body weight takes place cows yield dairy product in excess of the amount provided for by the food consumed, the excess of yield depending upon the rate of loss in weight of body. In some instances it is more than twice the amount provided for by the available nutriment.

"(3) The excess yield of dairy products gradually decreases until about the eleventh week, when an equilibrium generally obtains between the nutriment consumed and dairy products yielded, though in this respect cows differ; those of a pronounced dairy temperament taking less time, while those not strong in dairy temperament decrease more slowly in weight and require more time to reach normal work in milk production. Before such equilibrium is reached the body fat and possibly other substances contribute directly or indirectly to product.

"(4) The normal net nutriment requirements to a pound of butter fat is approximately 6.25 lbs., with a slight increase by cows yielding milk containing a low per cent of butter fat, and less with cows giving milk containing a high per cent of butter fat.

"(5) The normal net nutriment requirements to a pound of milk solids yielded is approximately 2.4 lbs., with a slight increase with cows yielding milk rich in butter fat and less with cows giving milk containing a low per cent of butter fat.

"(6) When the daily nutriment available for product and the products yielded daily are reduced to an approximate common value of energy, it is found that it requires about 1.75 lbs. of available nutriment to 1 lb. of product; that is, of the available nutriment, 43 per cent is expended in energy and 57 per cent is returned in the milk solids.

"(7) The daily yield of butter fat in excess of the nutriment supply, by virtue of an average daily loss per cow of 2 lbs. in body weight, was 0.283 lb., being a sacrifice of 7 lbs. in body weight to 1 lb. of butter fat yielded in excess of that provided for in the ration.

"(8) When the normal working condition of body weight is reached the nutriment required to a pound of butter fat and a pound of milk solids remains quite constant for an indefinite time under proper management."

A study of rations fed to milch cows in Connecticut, C. S. PHELPS (*Connecticut Storrs Sta. Rpt. 1901, pp. 81-104*).—This work was begun in 1892 and has been reported upon from time to time (*E. S. R.*, 13, p. 983). The objects have been to study the rations in use by farmers, to offer suggestions for the improvement of such rations, and to study the economy of feeding according to the yields of butter fat. During the 7 years previous to 1900, 37 studies were made, the results of which showed that too little attention has been paid to the proportion of protein used in feeding cows and too little effort has been made to feed according to the productiveness of cows. The work during 1900 and 1901 related to feeding according to the yields of butter fat, and is summarized by the author as follows:

"Four herds of cows were studied during the winter of 1900-1901. Two tests were made with each herd, covering periods of 12 days each in all except one test, which lasted 11 days.

"In the first test the entire herd was fed the ration in use by the dairyman, which usually was nearly the same for all cows of the herd. The amount of protein in the ration varied for the different herds from 1.75 to 2.40 lbs. per cow per day.

"In the second test the ration was varied according to the yields of butter fat produced in the first test. Two grain mixtures were used in this test; the first was included with the coarse fodders in what was called a basal ration, which was planned to contain about the same amount of protein as the average ration used in the first test; the second grain mixture, called a protein mixture, was chiefly made up of concentrated nitrogenous grain feeds, combined in such proportions as to furnish in the different cases 0.2 and 0.3 lb. of protein for each pound of the mixture. The plan of feeding in this test was to use the basal ration uniformly for all cows in

the test and to add to this certain quantities of the protein mixture, varying for the different cows according to the average daily amount of butter fat they had produced in the first test."

The following table summarizes the result of each test:

Original and suggested rations fed to dairy cows.

	Average weight of cows.	Digestible protein.	Fuel value.	Nutritive ratio.	Total cost of ration.	Cost, less value of manure.	Daily yield of milk.	Daily yield of butter.	Total cost of 100 lbs. milk.	Total cost of 1 lb. butter.
	Lbs.	Lbs.	Calories.		Cents.	Cents.	Lbs.	Lbs.	\$1.21	Cents.
Herd T:										
First test.....	750	1.75	27,960	1:7.6	17.0	10.3	14.1	0.87	\$1.21	19.5
Second test ..	750	1.90	24,860	1:6.0	17.1	10.1	14.7	.94	1.16	18.2
Herd U:										
First test.....	725	1.77	29,480	1:8.0	18.6	11.8	17.4	.98	1.07	19.0
Second test ..	725	2.44	29,610	1:5.5	19.9	11.5	18.0	1.10	1.10	18.1
Herd V:										
First test.....	800	2.19	35,140	1:7.6	21.7	13.0	19.4	1.04	1.12	20.9
Second test ..	800	2.31	30,320	1:6.0	19.6	11.4	19.1	1.06	1.03	18.5
Herd W:										
First test.....	900	2.40	30,990	1:5.9	20.1	11.8	19.6	1.03	1.03	19.5
Second test ..	900	2.74	29,710	1:4.8	20.0	11.1	18.1	1.00	1.10	20.0

"The cost of the average ration was less in the second test for 1 herd, practically the same for 2 herds, and was more in the second test for 1 herd. The average food cost of producing 100 lbs. of milk was less in the second test for 2 herds and was more for the other 2 herds. The average food cost of 1 lb. of butter was less in the cases of 3 herds and more in the case of 1 herd in the second tests.

"When the food cost of producing milk and butter is compared by groups of cows fed different amounts of protein in the first and second tests, it appears that the cost of producing 1 lb. of butter was less in nearly all groups in the second test than in the first, when the amount of protein in the second test was not more than about 2.6 lbs. per day. The gains in yields and profit in the second tests seem to be most marked when the results from the use of from 1.9 to 2.4 lbs. of protein are compared with those from the use of smaller quantities.

"The economy of feeding according to the yields of milk or butter fat depends much upon what yields are taken as a basis. In these experiments, where about 2 lbs. of protein was used as a basal ration for a yield of 0.5 lb. of butter fat daily, and the protein was increased from 0.20 to 0.27 lb. for an increase of from 0.15 to 0.20 lb. of butter fat, the food cost of production was generally less, until the protein reached about 2.6 lbs., than where uniform rations with smaller amounts of protein were used. The number of experiments is too small and the variations in the amounts of protein fed are too limited to be used as a basis for judging the amounts of protein needed for a given yield of butter fat; but the indications are that the amount of protein fed should be between 1.9 and 2.5 lbs., varying according to the productiveness of the cow."

Value of sugar beets as a food for milch cows, G. W. BERGLUND (*Nord. Mejeri Tidn.*, 18 (1903), No. 4, pp. 43, 44).—Sugar beets were fed to 32 cows, in quantities ranging for the 5 different groups from 10 to 25 kg. per head daily. The grain feed given was 1 kg. malt sprouts, 1 kg. wheat bran, $\frac{1}{2}$ kg. each of peanut meal and sunflower-seed cake, $\frac{1}{4}$ kg. rape-seed cake, with straw and hay as roughage. The experimental periods lasted from 19 to 23 days. The highest returns were obtained with cows fed 20 kg. of beets per day, those fed 10 kg. coming second. The author concludes that sugar beets are an excellent food for milch cows; they increase the milk flow perceptibly without affecting the fat content of the milk, and may be advantageously used to take the place, in part, of starchy concentrated foods in the feeding of milch cows.—F. W. WOLL.

Official tests of dairy cows, 1901-2, F. W. WOLL (*Wisconsin Sta. Rpt. 1902*, pp. 107-127).—Tabulated data are given for tests of 196 pure-bred cows representing Holstein, Guernsey, Jersey, and Red-Polled breeds and belonging to 19 different breeders. Many of the cows were tested more than once. The rules governing the tests are included. The work of testing pure-bred cows was begun by the station in 1894. The average production of the Holstein cows in 7 days was as follows: Cows 5 years old and over (55 tests), 401.5 lbs. of milk and 14.275 lbs. of fat; cows 4 years old (29 tests), 380.6 lbs. of milk and 13.412 lbs. of fat; cows 3 years old (44 tests), 370.2 lbs. of milk and 13.253 lbs. of fat; cows 2 years old (64 tests), 282.1 lbs. of milk and 9.851 lbs. of fat.

Investigations of methods of milking, F. W. WOLL (*Wisconsin Sta. Rpt. 1902*, pp. 75-106, pls. 2).—This is a résumé of Bulletin 96 of the station (E. S. R., 14, p. 694).

Efficiency of a covered pail in excluding filth and bacteria from milk, W. A. STOCKING, JR. (*Connecticut Storrs Sta. Rpt. 1901*, pp. 105-121, fig. 1).—Comparative determinations were made of the amount of dirt in milk drawn into an open pail and into an ordinary pail provided with a closely fitting cover, having on one side a funnel 4 in. in diameter, across the bottom of which was a fine wire gauze. When in use a few layers of cheese cloth were held in place above the wire gauze by means of a second funnel fitting loosely inside the first. The milking was done under favorable conditions as regards cleanliness. Of several methods tested for determining the amount of dirt in the milk, the following was found most satisfactory:

"The sample of milk was heated to 90° F., and was then run through a separator the bowl of which had also been warmed to 90° by running through it warm filtered water, the amount and temperature of the water necessary for the purpose having been previously ascertained. The milk was poured directly from the sampling flask into the receiving cup of the separator, thus avoiding any error that might arise from pouring it through the supply tank. The sampling flask was then washed with warm filtered water, and this was also poured into the bowl. After that filtered water at 90° was run through in sufficient quantity to wash out the greater part of the milk from the dirt residue. If the bowl was running at the proper speed before the milk was poured in, and if the speed was maintained till the overflow had entirely ceased, there would be left in the bowl a watery liquid containing the dirt from the sample and a small percentage of milk; but when the work was properly done there would be no fat left in the bowl to interfere with the subsequent filtering. The contents of the bowl, which consisted of the dirt residue and small quantities of milk, were then collected in a small dish by means of repeated washing, and these were filtered through a filter paper which had previously been dried in a desiccator and weighed. In order to free the residue on the filter paper from all trace of milk it was necessary to wash it for several hours with warm filtered water. After washing until the filtrate showed no traces of cloudiness the paper with the dirt was again dried in the desiccator and weighed, and the weight of the dirt computed."

On an average for 15 tests 0.1103 gm. of dried insoluble dirt was removed from 1 liter of milk drawn into the open pail, and 0.0408 gm. from 1 liter drawn into the covered pail, showing that 63 per cent of dirt was excluded by the cover. Milk drawn into an open pail was compared with milk drawn under similar conditions and strained immediately after milking. Straining removed 46.6 per cent of the dirt. Studies were also made of the germ content and keeping qualities of the milk obtained by the different methods, with the results summarized by the author as follows:

"In the fresh milk from the covered pail the total number of bacteria was about 71 per cent, and the number of acid bacteria about 59 per cent of those in the fresh milk from the open pail. In the fresh strained milk the total number of bacteria was 89 per cent and the number of acid bacteria 83 per cent of those in the milk not strained.

"After the milk had stood for 50 hours at constant temperature of 70° F. the average for the total number of bacteria was larger in the milk from the covered pail than in that from the open pail; while the average for the acid producing species was larger in the latter than in the former. In the strained milk both the total number and the number of acid bacteria were larger than in the milk not strained.

"The milk from the covered pail curdled sooner than that from the open pail, the average difference being about 7 hours; likewise the strained milk curdled sooner than the milk not strained, the average difference being also about 7 hours. This fact, however, is of but little moment since any of these samples had they been kept at the usual temperatures for handling milk would have remained sweet longer than milk is usually kept.

"The results of these tests would seem to indicate that the covered pail is more efficient for the production of pure milk than straining milk drawn into an open pail. It is quite evident also that to keep the dirt out of the milk in the first place is much better than straining it out after the milking. A considerable portion of the dirt dissolves quickly in the warm milk and thus introduces a contamination that can not be strained out."

The comparative growth of different species of bacteria in normal milk, H. W. COXN and W. M. ESTEN (*Connecticut Storrs Sta. Rpt. 1901, pp. 13-80*).—The importance of a better knowledge of the development of different species of bacteria in milk under normal conditions is briefly discussed, the method of investigation used by the authors is described, and the following 3 series of experiments are reported upon in detail and summarized: (1) The comparative growth of different species of bacteria in milk at 20° C.; (2) the effect of icing milk upon the development of bacteria; and (3) the comparative growth of bacteria in milk at temperatures of 20 and 13°.

The method of study has been noted briefly from another source (E. S. R., 14, p. 907). The culture medium is prepared in practically the same way as ordinary gelatin, with the addition of litmus and milk sugar. The sample of milk to be tested is properly diluted and plate cultures are made. The colonies are counted after several days to determine the total number and the number of different kinds. The necessity of keeping the plates 3 to 5 days or longer is considered the most serious fault of the method, as under certain conditions complete liquefaction takes place before the colonies can be differentiated. The authors have been able to differentiate about 30 species of bacteria by their method. The forms most commonly found in milk a few hours old were *Bacillus acidi lactici*, *B. acidi lactici* II, *B. lactis aerogenes* (from which *B. coli communis* was not differentiated), several allied species designated the Streptococcus group, rapid and slow liquefying bacteria, and 2 species of Sarcina. While the differentiation is considered only approximate, the authors are convinced that the error is not very great.

The 3 series of experiments as a whole showed little regularity in the comparative development of the different species of bacteria in milk. The number of bacteria at any stage was found to be more dependent upon temperature than upon the original contamination. As regards the development of the bacteria, 2 periods were recognized, the first, in which the number of bacteria was less than 10 million per cubic centimeter, lasting from 24 to 50 hours according as the temperature was 20 or 13°, and the second, in which the number of bacteria was above 10 million, lasting from the end of the first period until the time of curdling. Some of the changes which occurred during the first period may be noted as follows: The number of bacteria in milk was not increased, but was frequently reduced during the first few hours after milking. At 20° most of the species began to increase in absolute numbers after the first 6 hours, *B. acidi lactici* increased uniformly, the other lactic acid bacteria were irregular in their development, the Streptococcus group always increased, the liquefying bacteria practically always increased in absolute and sometimes in relative numbers, the species of Sarcina developed but little, and the miscellaneous species

decreased slightly during the first period. At 13° the original period of no growth was increased, the number of bacteria at the end of 50 hours being no greater than that in milk at 20° after 18 hours. The rapid development of bacteria after 40 hours was most frequently due to the growth of the *Streptococcus* group, rather than to the lactic-acid bacteria. The development of the miscellaneous species was favored by the lower temperature. The preliminary icing of milk for a period of 15 hours greatly reduced the number of bacteria, the number present at the time of curdling being much less than in samples not previously iced. The preliminary icing favored the development of a number of miscellaneous species, but delayed the development of the *B. acidi lactici*.

During the second period the lactic-acid bacteria, especially *B. acidi lactici*, increased with marvelous rapidity, their number sometimes reaching 99 per cent of the total number of bacteria. The other species decreased in both relative and absolute numbers. The liquefying bacteria frequently disappeared entirely.

The presence of tubercle bacilli in market milk and butter, PAWLOWSKY (*Compt. Rend. 10. Cong. Internat. Hyg. et Démogr., Paris, 1900, pp. 187-189*).—As determined by inoculation experiments with guinea pigs tubercle bacilli were present in 1 out of 51 samples of milk and in 1 out of 54 samples of butter examined. A bacillus resembling the tubercle bacillus was also present in 3 of the samples of butter.

A new method of sterilizing milk, C. C. L. BUDDE (*Nord. Mejeri Tidn., 18 (1903); No. 5, pp. 65, 66*).—The method depends on the action of nascent oxygen on the micro-organisms in milk at a temperature above 40° C.; it consists in the addition of a small quantity of hydrogen peroxid to the milk (0.9 gm. per liter) and heating rapidly to 50°; or hydrogen peroxid may be added to milk previously heated to about 50°, so that it will contain about 0.35 gm. of hydrogen peroxid to the liter; in either case the subsequent heating of the milk is continued for 5 to 6 hours. An excess of hydrogen peroxid may be rendered innocuous by the addition of a sterile infusion of common yeast. The author has applied for a patent for the method in European countries.—F. W. WOLL.

Sterilization of milk by means of peroxid of hydrogen, C. BARTHEL (*Nord. Mejeri Tidn., 18 (1903), No. 11, pp. 139-141*).—The author discusses the results of the investigations of Heidenhain, Henrietta Chick, J. Huwart, and A. Rosam on the use of hydrogen peroxid for the sterilization of milk and reports a number of experiments which he conducted on this point, with special reference to the Budde method of milk sterilization (noted above). The amount of undecomposed hydrogen peroxid in the milk was determined in the following manner: $\frac{1}{2}$ cc. of dilute sulphuric acid (1:3) was added to 25 cc. of milk, and to 5 cc. of the clear filtrate 10 cc. of a 10 per cent potassium iodid solution and 5 cc. of sulphuric acid (1:3) were added. The free iodin was then titrated back with a tenth normal thio-sulphate solution, after having been left standing in a dark place for 4 hours and frequently shaken. It was found that an excess of only 0.05 gm. of hydrogen peroxid per liter of milk is plainly noticeable by taste. If only a trace or no undecomposed peroxid is present the milk will remain sweet for a longer or shorter time, according to the temperature at which the milk is kept, but after some time, when the bacteria recover from the effects of the peroxid, decomposition of the milk will begin. The practicability of the Budde method is questioned by the author because the amount of peroxid required for different kinds of milk can only be determined by frequent exact chemical titrations, and also because the commercial 3 per cent peroxid, partly on account of its impurities and partly on account of its dilution, can not be used in practical work, while the chemically pure peroxid is too expensive to be used under such conditions.

The author finds that milk to which minimum quantities of peroxid (e. g., 0.1 gm. per liter) are added after heating to from 45 to 50° C. for some minutes, will

react toward the Storch paraphenylenediamine test like milk which has been pasteurized at 80° C. or above.—F. W. WOLL.

Observations on the use of acid tests for milk and cream, E. H. FARRINGTON (*Wisconsin Sta. Rpt. 1902, pp. 128-135*).—The results of several tests are reported. It was found that standard alkaline solutions used in the determination of acidity in milk and cream were unaffected by freezing and thawing, provided all the ice was melted before the liquid was used. While the dry alkaline tablets keep indefinitely, the solutions prepared from them were found to lose in strength after keeping for about 1 week. When a solution was allowed to remain in the burette over night the loss in strength was noticeable. The curd and the whey in the same sample, even after standing for 8 days, were shown to neutralize different amounts of alkali, emphasizing the importance of thorough mixing before testing. Determinations of the acidity in samples of cream containing from 25 to 50 per cent of fat and kept under uniform conditions showed maximum degrees of acidity, varying with the fat content. The maximum amount of acid developed in skim milk was 0.78 per cent, in 25 per cent cream 0.6 per cent, and in 40 per cent cream 0.5 per cent. Only 0.11 per cent of acid developed in cream containing 50 per cent of fat before the sample was too thick to draw into the pipette.

A modified cream-test bottle, E. H. FARRINGTON (*Wisconsin Sta. Rpt. 1902, pp. 147-149, fig. 1*).—The author condemns a tendency on the part of manufacturers to increase the diameter of the necks of cream-test bottles, permitting in some cases the entire graduation from 0 to 30 per cent to occupy a space of only 2 in. in length. In the modified test bottle designed by the author and here figured and described the capacity of the bulb is decreased from about 55 cc. to about 45 cc., which is considered large enough when the quantity of cream is 18 gm. The diameter of the neck is decreased so that the graduated scale occupies about twice the usual length, permitting readings of $\frac{1}{4}$ per cent. The bottle is of the usual length of a milk-test bottle.

The composition of frozen milk, E. H. FARRINGTON (*Wisconsin Sta. Rpt. 1902, pp. 136, 137*).—Analyses were made of 3 lots of milk before freezing, of the liquid portion of samples containing different amounts of ice, and of the melted ice. When about 25 per cent of the sample was frozen the fat content of the liquid portion was about 0.5 per cent higher and of the ice about 1 per cent lower than that of the original sample. When from 40 to 50 per cent of the milk was frozen there was no great difference in the fat content of the liquid and iced portions. The casein, ash, and milk sugar were not separated very much by freezing.

Ekenberg's "desiccator" (*Nord. Mejeri Tidn., 18 (1903), No. 8, pp. 99, 100*).—A description is given of the apparatus constructed by M. Ekenberg for the manufacture of the "milk flour" invented by him (*E. S. R., 14, p. 804*). An analysis of the product shows its composition to be as follows: Albuminoids 36 per cent, carbohydrates 49 per cent, fat 1 per cent, mineral matter 7.5 per cent, and moisture 6.5 per cent.—F. W. WOLL.

Swedish butter exhibits, 1901, N. ENGSTRÖM (*Meddel. K. Landtbr. Styrs. [Sweden], 1902, No. 79, pp. 47*).—During the year 359 creameries took part in the exhibits. In all, 1,374 tubs of butter were exhibited. The average water content of the butter was 13.3 per cent, the range being from 9.7 to 20.4 per cent. Of the total number of creameries 327 furnished butter made from pasteurized cream for all and 13 creameries for some of the exhibits in which they participated, while 8 did not pasteurize the cream, and 11 failed to give information on this point. Pure-culture starters were used throughout the year by 43.4 per cent of the creameries and buttermilk starters by 37.6 per cent. Sweet-cream butter was made by 7 per cent and radiator butter by 3.9 per cent of the creameries. A marked beneficial effect of the pasteurization of the cream, as regards the quality of the butter made from it, is apparent from the scores presented in the report.

The average fat content of 871 samples of separator skim milk examined during the year was 0.12 per cent, the figures for the different separators ranging between 0.07 per cent and 0.23 per cent. Of the 556 samples of buttermilk tested, that from pasteurized cream contained, on the average, 0.49 per cent of fat, and that from raw cream 0.50 per cent; the lower and upper limits obtained in the former case being 0.23 and 1.67 per cent and in the latter case 0.31 and 0.83 per cent. The average loss of fat in the skim milk was 0.104 lb. per 100 lbs. of milk, and in the buttermilk 0.049 lb., the total figures in the case of pasteurized butter being 0.143 lb. and in the case of raw-cream butter 0.169.—F. W. WOLL.

Water content of butter, L. F. ROSENGREN (*Nord. Mejeri Tidn.*, 18 (1903), No. 3, pp. 37, 38).—The following conclusions are drawn from the results of investigations of the relation of churning conditions to the water content of butter: A low water content may be obtained by various methods of procedure—by lowering the churning temperature, by washing the butter well with cold water and allowing the washings to drain thoroughly, by salting before working, and by postponing the second working in until the butter has become hardened in the refrigerator room (preferably until the next morning). Numerous analyses are given of butter made under different conditions as to time and methods of working, salting, etc.—F. W. WOLL.

The composition of process or renovated butter, C. A. CRAMPTON (*Jour. Amer. Chem. Soc.*, 25 (1903), No. 4, pp. 358-366).—Previously noted (*E. S. R.*, 14, p. 523).

Conditions affecting the character of butter fat, T. E. THORPE (*Jour. Biol. Agr.* [London], 9 (1903), No. 4, pp. 447-460).—This is a general discussion of the subject, several methods of analysis being described and investigations by Werenskiöld in Norway, Boggild and Stein in Denmark, and others being reviewed.

Pasteurized cream butter, E. H. FARRINGTON and J. H. GODFREY (*Wisconsin Sta. Rpt.* 1902, pp. 138-142).—Pasteurization of cream in butter making, which is not commonly done in American creameries at the present time, is considered as theoretically a promising way of overcoming one of the most common faults in creamery butter, namely, the lack of uniformity in quality. In experiments along this line from 1,000 to 1,500 lbs. of sweet cream was mixed and divided into 3 lots, one of which was cooled to 50° F. and churned sweet; one heated to 185 to 190° in a continuous pasteurizer, cooled immediately to 54°, and then ripened at 75° with a pure culture; and one ripened at 70 to 75° with the same starter, without previous pasteurization. The experiment was repeated a number of times during the period from April to July. Notes are given on the butter made from the sweet cream, pasteurized cream, and raw cream. "The sweet-cream butter was at its best when made. It did not improve with age, but rapidly deteriorated, becoming decidedly off-flavor in 3 weeks' time. The pasteurized-cream butter was much better than the sweet-cream butter, and its flavor improved or became more pronounced until it was 5 weeks old. After about 3 weeks the flavor was fully as good as the fresh raw-cream butter and during this time very little, if any, objection could be made to it." The raw-cream butter was also at its best when first made. The body of the pasteurized butter was not defective at any time, which is attributed to the method of heating and cooling used.

Difficulties in the way of drawing conclusions from experiments in butter making when based on one judge's scores, E. H. FARRINGTON (*Wisconsin Sta. Rpt.* 1902, pp. 143-146).—The scores of the judges in the above experiments are given and commented upon. "The differences in scores suggest that when important matters are at stake, the opinions of a number of judges working independently or in sets of three judges should be obtained, each tribunal making its report independently of the other, and none of them knowing anything about the history of the butter scored."

Influence of cold curing on the quality of Cheddar cheese, S. M. BABCOCK, H. L. RUSSELL, A. VIVIAN, and U. S. BAER (*Wisconsin Sta. Rpt.* 1902, pp. 150-164).—This

is an account of a continuation of the investigations described in the last report of the station (E. S. R., 13, p. 988). The results of the work as a whole were included in Bulletin 94 of the station (E. S. R., 14, p. 490), in which the advantages and disadvantages of cold curing were considered at length.

Influence of temperatures approximating 60° F. on the development of flavor in cold-cured cheese, S. M. BABCOCK, H. L. RUSSELL, A. VIVIAN, and U. S. BAER (*Wisconsin Sta. Rpt. 1902, pp. 165-173*).—Examinations of cheese which had been thoroughly ripened in cold storage were made at frequent intervals during 1 year to determine the effect of subsequent exposures to high temperatures. The results are presented in detail and discussed and the following conclusions are drawn:

“(1) The mild flavors which characterize cold-cured cheese may be intensified by subsequent exposure to somewhat higher temperatures (approximately 60° F.). The flavor so produced does not partake of the sharp tang usually found in old cheese cured at high temperatures. Care must be taken not to have this temperature too high nor maintained too long, as in a partially cured cheese this subsequent enhancement in flavor rapidly occurs.

“(2) In order to hold the desirable flavors for the longest possible time, and so lengthen the commercial ‘life’ of the cheese, the same should be returned to lower temperatures for storage as soon as the desired flavor is reached. Under such conditions further development is stopped and such cheese may be held unimpaired for many months.

“(3) With cheese made from first-class milks the rate of ripening can be hastened by a brief preliminary exposure to a higher temperature (not much exceeding 60° F.), but the improvement in the product both as to nature and keeping quality of same when cured at low temperatures makes it preferable to employ low temperatures for the bulk of the curing. Where consolidated cold-curing stations are established, transportation of the green product from the factories requires a brief period (a few days) during which time no damage is likely to occur. With imperfect milks there is always danger in curing even for a brief period at temperatures normally employed. The cold-curing system is more likely to give favorable results with such milks.”

Influence of varying quantities of rennet on cold-cured cheese, S. M. BABCOCK, H. L. RUSSELL, A. VIVIAN, and U. S. BAER (*Wisconsin Sta. Rpt. 1902, pp. 174-179, fig. 1*).—In earlier investigations at the station (E. S. R., 13, p. 87), it was shown that the ripening of cheese may be hastened by the use of additional quantities of rennet. In several of the cold-curing experiments referred to above advantage has been taken of this fact to hasten the ripening of the cheese. Three, six, and nine oz. of rennet per 1,000 lbs. of milk have been used. The results are considered as showing that at 32° and 40° F. 9 oz. of rennet can be used with safety. “However, the cheese made with 6 oz. of rennet were also quite as good and ripened up nearly as rapidly. They also had a tendency to hold the mild flavor better than the 9 oz. goods, and it is our judgment that the use of 6 oz. under cold-curing conditions is perhaps preferable to a higher amount. These experiments thoroughly demonstrate that larger than normal quantities can be used with advantage, in that they give a more buttery and softer texture and also hasten the ripening course.”

Conditions affecting the development of white specks in cold-cured cheese, S. M. BABCOCK, H. L. RUSSELL, A. VIVIAN, and U. S. BAER (*Wisconsin Sta. Rpt. 1902, pp. 180-183*).—In the last report of the station (E. S. R., 13, p. 989), the almost invariable occurrence of small white specks in cold-cured cheese was reported. The specks did not apparently affect the flavor or texture of the cheese in any way. Conditions affecting their formation were investigated, with the following results:

“The chief factors determining the formation of white specks in Cheddar cheese seem to be that of temperature and salt. Low temperatures favor very much the production of these specks. Rarely do they appear at 60° F. except where other conditions are peculiarly favorable for their production. The addition of salt tends

to prevent their formation under all conditions. Also they are not so apparent when increased quantities of rennet are used. They are especially abundant in skim cheese, but do not appear in very rich cheese even at low temperatures. In sweet-curd cheese no specks were found at any temperature."

Cheese experiments with yeast cultures according to O. Johan-Olsen's method, S. J. BENTERUD and O. IVERSEN (*Aarsber. Offent. Foranstalt. Landbr. Fremme, 1901, pt. 3, pp. 84*).—Pure cultures of yeasts obtained from Dutch clove cheese, Gouda, Gorgonzola, and Norwegian Old Cheese (Gammelost), according to the method of Dr. O. Johan-Olsen, were used in the manufacture of such cheeses on a commercial scale. Sixty-five experiments in the manufacture of Dutch clove cheese were made, at two different factories, a total quantity of 30,392 kg. of separator skim milk being used in the experiments. Two or three control cheeses were made in each experiment, in a different room from that in which the pure-culture cheeses were made. The pure cultures were used both in connection with pasteurized and raw skim milk. The cheeses were kept for about 7 months before being scored. The average score for control cheeses made from raw milk was 8.5 points, and for experimental cheese, 10.3 points. In experiments where pure cultures were added to pasteurized milk and control cheeses were made from raw milk the scores were: Control cheese, 9.6 points; experimental cheese, 9.5 points. When pasteurized milk was used for all cheeses, the scores averaged 11.3 points for control cheese and experimental cheese alike. The average scores for all cheeses made in the three series was 9.3 points for control and 10.2 points for experimental cheese. The results show that good cheese can be made from pasteurized milk by the method of pure-yeast cultures. The most uniform results were obtained with raw milk without the use of pure cultures, but the quality of the cheese was in general somewhat improved by the use of the proper pure culture, whether pasteurized or raw milk was used for the manufacture of the cheese.

In the manufacture of Gouda cheese 56 experiments were made, in which 25,852 kg. of new milk and 6,638 kg. of skim milk were used. The average fat content of the milk was 2.76 per cent. The age of the cheese at the time of scoring was about 6 months at one of the factories where the experiments were conducted and about 4 months at the other factory. The following average scores were obtained: Control cheese from raw milk, 10.1 points; experimental cheese from raw milk, 9 points; control cheese from pasteurized milk, 10.4 points; experimental cheese from pasteurized milk, 10.6 points; where pasteurized milk was used for the experimental cheese and raw milk for the control, the average scores were, 9.1 points for the control and 11.1 points for the experimental cheese. The average score was 0.9 point higher in favor of pure cultures. The greatest benefit was derived from the use of pasteurized milk in the manufacture of the cheese.

Gorgonzola cheese was made in 56 experiments with 16,852 kg. milk of an average fat content of 3.34 per cent. The average scores for all experiments when the cheeses were about 7 months old were 11.9 points for the control cheese and 10.7 for the experimental cheese. No advantage was obtained by the use of the pure-yeast cultures in the manufacture of this cheese, either in the case of raw or pasteurized milk. The pure-culture cheese made from pasteurized milk also scored lower than the control cheese made from raw milk. The experiments in the manufacture of Gammelost gave a similar result; the yeast cultures apparently failed to exert any beneficial influence as regards the quality of the cheese.

Accounts of experiments on the use of calcium chlorid and grated cheese in the manufacture of pasteurized-milk cheese and on the influence of pasteurization on the yield and quality of Primost cheese are also presented in the report.—F. W. WOLL.

Notes for cheese makers, J. A. RUDDICK (*Canada Dept. Agr., Comr.'s Branch, Dairy Division Bul. 9, n. ser., pp. 7*).—This consists of 53 suggestions relating to cheese making.

Cheese making on the farm, H. E. ALVORD (*U. S. Dept. Agr., Farmers' Bul. 166*, pp. 16, figs. 3).—Directions compiled from various sources are given for the manufacture on the farm of several varieties of cheese.

Modern dairy science and practice, L. L. VAN SLYKE (*Pennsylvania Dept. Agr. Bul. 104*, pp. 127, pls. 4, figs. 8).—This bulletin is a treatise on dairying in its restricted sense of a manufacturing industry. Chapters are devoted to the chemistry of milk, continuation of milk, preparation of milk for market, cream, butter making, the relation of milk to yield of butter, preliminaries of cheese making, making Cheddar cheese, curing cheese, qualities of cheese, the relations of milk to cheese, methods of testing milk and its products, and special dairy products.

The statistics of the dairy, H. E. ALVORD (*Proc. Soc. Prom. Agr. Sci. 1902*, pp. 50-62).—This is a discussion of the condition of the dairy industry in the United States as shown by the Twelfth Census.

VETERINARY SCIENCE AND PRACTICE.

Modern theories of bacterial immunity, H. C. ERNST (*Boston: Journal Medical Research, 1903*, pp. 123).—This volume contains an abstract of a series of lectures delivered on this subject at the Harvard Medical School. The author presents a glossary of terms relating to immunity, in which attempt is made to indicate so far as possible the various meanings ascribed to these terms by different writers. The main body of the volume is occupied with a careful examination of the theories of Metchnikoff and Ehrlich. As a result of the author's study of these 2 theories it is concluded that they are not so contradictory as is generally supposed. According to both theories, 2 substances are required in active immunity, viz, immune body and complement. Metchnikoff insists that these substances remain in the phagocytes, while Ehrlich and his followers claim that they exist in the blood serum.

A review of current theories regarding immunity, J. RITCHIE (*Jour. Hyg. [Cambridge]*, 2 (1902), Nos. 2, pp. 214-250; 3, pp. 251-285; 4, pp. 452-464).—The author presents a critical review of this subject, in connection with a bibliography of 106 titles. The chief theories which have been proposed in explanation of the phenomena of immunity are discussed in detail. The author believes that the study of immunity as at present prosecuted leads to results of great biological significance. The results may be considered as forming a contribution to an understanding of the complex processes of metabolism.

Investigations on the antibodies of spores, W. DEFAILLE (*Ann. Inst. Pasteur, 16* (1902), No. 10, pp. 756-774).—The experiments reported in this paper were made for the purpose of determining the influence of bacterial spores upon animal sera. The experimental animals chosen by the author were dogs and guinea pigs, and the bacterial organisms used were *Bacillus mycoides*, *B. mesentericus vulgaris*, *B. subtilis*, *B. alvei*, the first anthrax vaccine, and anthrax bacilli attenuated by carbolic acid. The result of the author's numerous experiments with the spores of these organisms indicate that the injection of bacterial spores into animals is followed by the production of antibodies (agglutinins and sensibilizing substances). The injection of the spores of molds, however, does not produce this special power in the serum. The development of antibodies is certainly the result of the resorption of the spores as such and not of their germination in the organism, since it is shown that the results are the same, whether the spores are injected in a dead or living condition. The antibodies produced by the spores are also active toward the spores of other organisms. In the formation of antibodies in animals spores exercise an action very different from that of the bacteria themselves. Living or slightly attenuated bacilli produce agglutinating and sensibilizing properties in the serum, while bacilli heated to a temperature of 115° C. produce only agglutinins. Spores, on the other hand, when heated to a temperature of 115° C. produce both agglutinins and sensibilizing

substances in the animal sera. The antibodies thus formed in animal sera do not furnish reliable means for the recognition of the species of spores.

Immunization against immune serum, E. W. A. WALKER (*Jour. Path. and Bact.*, 8 (1902), No. 1, pp. 34-51).—The experiments reported in this paper were chiefly concerned with the change induced in bacteria by their growth in immune serum, and the change in the susceptibility of guinea pigs to specific infection due to previous treatment with increasing doses of serum. The immune serum used was the antityphoid serum of Tavel. It was found during the author's experiments that bacteria may be immunized against their immune serum, and may thus be increased in virulence, and become less readily agglutinable. An immune serum in which the corresponding bacillus has been cultivated is thereby rendered less agglutinative and less effective against the bacillus. It was also found that animals may be immunized against immune sera. They are thereby rendered less capable of being protected by that serum, but their susceptibility to the bacterial organism is not increased. Agglutinins are considered true antibodies. The immune body of the same bacterial organism is held to be not identical in different animals, but exhibits especial characters for each species.

Note on toxic and antitoxic action in vitro and in corpore, E. F. BASHFORD (*Jour. Path. and Bact.*, 8 (1902), No. 1, pp. 52-69).—The author's experiments on the protective properties of sera were made largely with reference to the effect of these sera upon corrosive sublimate, saponin, solanin, digitalin, snake venom, ricin, tetanolyisin, etc. The experiments were conducted in 2 series, one in vitro and the other in experimental animals, and the results of the 2 series are compared. The author combats the idea that there is any artificially increased protective action in vitro, of the serum of animals immunized against any of these toxic agents, due merely to increase in constituents normally present. The apparent similarity of the reactions obtained in vitro and in experimental animals is briefly discussed by the author, and it is suggested that the protective action of normal serum in vitro be called pseudo-antitoxic in cases where the toxin is incapable of causing the production of the corresponding antitoxin.

Investigations concerning the protective and curative action of anthrax serum obtained from the dog, F. SANFELICE (*Centbl. Bakt. u. Par.*, 1. Abt., 33 (1902), No. 1, Orig., pp. 61-71).—While dogs have generally been considered as nearly or quite immune to ordinary infection with anthrax, the author found during numerous experiments that a certain number of dogs were readily infected, while others proved to be quite immune. After repeatedly inoculating dogs with attenuated cultures of anthrax at first and using cultures of greatly increasing virulence, it was found possible to secure a serum from dogs treated in this way which would protect experimental animals against fatal infection with virulent cultures of anthrax.

The destruction of toxins by peroxids and oxydases of animal and vegetable origin, N. SIEBER (*Arch. Sci. Biol. [St. Petersburg]*, 9 (1902), No. 2, pp. 151-170).—During the extensive investigations undertaken by the author on this subject it was found that calcium dioxide and oxygenated water would destroy the toxins of diphtheria and tetanus. Oxydases of animal and vegetable origin neutralize the toxins of these diseases. The destructive action of oxydases toward toxins manifests itself not only in vitro, but also in the body of the experimental animal, provided the mixture of the toxin and oxydase are injected subcutaneously. The oxydases are capable of exercising their action on small doses of toxins, even when these substances are injected into the animal at different points. It was found that the destruction of toxin by emulsions containing oxydases takes place only when the emulsions give the color reactions which would be characteristic for the oxydases.

The bactericidal action of certain aromatic substances, H. MARX (*Centbl. Bakt. u. Par.*, 1. Abt., 33 (1902), No. 1, Orig., pp. 74-76).—Experiments were tried to determine the effect of turpentine oil and nitrobenzol on anthrax bacillus and

Staphylococcus pyogenes aureus. It was found that turpentine oil killed anthrax bacilli when applied in a concentration of 1 to 100 for a period of 60 minutes, while the staphylococci were killed by a concentration of 1 to 10 for the same period. Nitrobenzol, even in a concentration of 1 to 10, did not kill anthrax bacilli or staphylococci within a period of 24 hours.

Morphological changes in the blood during hemolysis, Y. FUKUIHARA (*Beitr. Path. Anat. u. Allg. Path.*, 32 (1902), No. 2, pp. 266-275, pl. 1).—The author studied the microscopic changes in the structure of the red blood corpuscles under the influence of substances which cause hemolysis. The animals from which material was obtained included pigeons, guinea pigs, rabbits, and carp. For producing hemolysis the author used weak solutions of soda (0.2 per cent) and various stains, such as crystal-violet, safranin, and methylene blue. The results of these investigations may be summarized as follows: Small portions of the red blood corpuscles are constricted off during the process of hemolysis; this phenomenon, however, is not especially characteristic of hemolysis, since it also occurs in the coagulation of the blood. The nuclei are set free and the coloring matter of the red corpuscles is gradually dissolved. After the red blood corpuscles lose their hemoglobin, they greatly resemble leucocytes and are distinguished from the latter chiefly by the fact that they become tiolated more rapidly.

The red blood corpuscles and infection, M. DOMINICI (*Arch. Med. Exper. et Anat. Path.*, Paris, 1. ser., 14 (1902), No. 6, pp. 681-728).—An extensive series of experiments was undertaken for the purpose of determining certain details in the behavior of the red blood corpuscles during the progress of infectious diseases in man and animals. The chief purposes of the author were to study the diapedesis and destruction of the red blood corpuscles, the behavior and excessive production of nucleated red blood corpuscles in the bone marrow and in the spleen, and the parallel reactions of the red and white blood corpuscles. The work of other authors on this subject is critically discussed, in connection with bibliographical references. The author infected experimental animals with coli bacillus, typhoid bacillus, and other organisms. It was found that the production of nucleated blood corpuscles in rabbits took place quite rapidly in the peripheral blood vessels at the beginning of septicemic infection. The author was unable to observe any evidence of extensive destruction of the red blood corpuscles in such affections as icterus and hemorrhages. The spleen is believed to be the only organ in which the red blood corpuscles are actually destroyed.

Structure and function of wandering cells, phagocytes, and pus cells, R. KLEMENSIEWICZ (*Beitr. Path. Anat. u. Allg. Path.*, 32 (1902), No. 3, pp. 351-434, pls. 3).—The investigations reported in this paper were undertaken for the purpose of explaining as far as possible the nature of leucocytes with polymorphous nuclei. The experimental animals were batrachia. The author found that the finely granulated leucocytes with polymorphous nuclei constitute a well-marked group of cells which occur not only as cells in the blood of the organs and larger vessels, but also as pus cells and phagocytes. The structure of the cytoplasm of these cells is characteristic and apparently constant. The author believes that all cells with polymorphous nuclei represent merely one kind of physiological structures which are not so strictly confined in function as are muscle or nerve cells. It is suggested as desirable that certain constant parts of these cells be distinguished by names, such as secretory apparatus, respiratory and excretory organs, motor organs, etc.

Infectiveness of milk of cows which have reacted to the tuberculin test, J. R. MOHLER (*U. S. Dept. Agr., Bureau of Animal Industry Bul. 44*, pp. 93, pls. 2).—As a result of the death of a number of cattle from rabies at the Government Asylum for the Insane, St. Elizabeth, D. C., post-mortem examinations were made when it was found that the herd was badly infected with tuberculosis. Twelve animals upon which post-mortem examinations were made were found to be extensively tuber-

culous. Notes are given on the history, care, and stabling of the herd. The animals were fed in the stable throughout the year. The herd consisting of 102 animals, was tested with tuberculin; of this number 76, or 74 per cent, gave a decided reaction; 10 of the animals which showed physical symptoms of tuberculosis also reacted to tuberculin, and of these 10, 5 were found to be unfit for food, while in the other the tuberculous alterations were confined to the lymphatic glands or were otherwise localized. The nonreacting animals were placed in a stable by themselves, after thorough disinfection of the premises, and the tuberculous herd was kept isolated and was cared for by separate attendants.

A series of experiments was made in testing the infectiveness of the milk of reacting animals by feeding and inoculation in guinea pigs. The literature of this subject is critically discussed by the author. In experiments made by the author a sample of milk was taken from each cow daily, the number of cows being 66. The milk was fed to guinea pigs and the centrifugalized cream was inoculated intraabdominally. Cover-glass preparations were also made from the sediment of both the milk and cream and were examined under the microscope after staining. The quantity of milk injected was from 1 to 3 cc. in each guinea pig. In a subsequent examination of the inoculated guinea pigs acid-proof bacteria other than tubercle bacilli were found in only 3 cases. Various other micro-organisms were found in connection with Moeller's grass bacillus. Among the 43 guinea pigs which were used as check animals in the experiments no case of tuberculosis developed. The author gives condensed statistics concerning each cow and the experiments made with her milk. From the feeding and inoculation experiments it was found that the milk of 9 different cows produced fatal tuberculosis when fed to guinea pigs, while the same result was obtained in 13 instances from intraabdominal injection. By combining the results from feeding and inoculation experiments it was found that 12 of the 56 reacting cows, or 21.4 per cent at one time or another gave milk which contained virulent tubercle bacilli. The virulence of the milk increased with the advancement of the disease. The asylum authorities decided to sell the reacting animals as soon as they became dry and thus gradually reduce the herd. After 6 months a second tuberculin test was made; of the 26 cows which were injected, 25 of which had failed to react in a previous test, 8 gave a decided reaction. A third injection 3 months later in 18 cows produced no reaction in any case. The author concludes from these experiments that the tubercle bacillus may be present in the milk of tuberculous cows without an affection of the udder, that tubercle bacilli may be excreted from such animals in sufficient numbers to produce fatal infection in experimental animals. It was found that the number of tubercle bacilli in the milk varies from day to day. The author recommends that "the milk of all cows which have reacted to the tuberculin test should be considered as suspicious and should be subjected to sterilization before using. Still better, tuberculous cows should not be used for general dairy purposes."

Human and bovine tuberculosis, N. RAW (*British Med. Jour.*, 1903, No. 2196, pp. 247, 248).—During the past 5 years the author has had under his care 1,750 human patients suffering with various forms of pulmonary tuberculosis and 273 children affected with *tabes mesenterica*. Post-mortem examination and bacteriological studies were made on a large number of these cases and inoculation experiments were conducted with the material thus obtained. As a result of the author's studies it is concluded that there are 2 distinct varieties of tuberculosis which affect man, one produced by the human tubercle and the other by the bovine tubercle. It is believed that these 2 forms of tuberculosis, while separate and distinct, may both affect man, the true human tuberculosis being usually the pulmonary form and bovine tuberculosis occurring ordinarily as an affection of the mesenteric glands and the alimentary tract. It is believed by the author that true human tuberculosis is always transmitted from one person to another by infection, but that every effort

should be put forth to stamp out tuberculosis in cattle, and that milk and tuberculous products should be sterilized before being eaten.

The transmissibility of human tuberculosis to cattle and goats, A. MOELLER (*Deut. Med. Wchnschr.*, 28 (1902), No. 40, pp. 718, 719).—The author conducted a number of experiments, during which attempts were made to inoculate calves with human tubercle bacilli by way of the mouth, by intraperitoneal, subcutaneous, and intravenous injections, and by inhalation. Similar methods were used in attempts to inoculate goats. During these experiments it was found to be impossible to infect calves with tubercle bacilli of human origin by any method whatever. The same negative results were obtained from sputum or pure cultures of tubercle bacilli of human origin, whether administered intravenously or given by way of the mouth. Similarly, tubercle bacilli of human origin which had first been passed through goats failed to produce an infection in calves. It was found that enormous quantities of the bacilli could be fed to goats or be inoculated intraperitoneally without producing any infection.

Transmission of tuberculosis of man to cattle, J. FIBIGER and C. O. JENSEN (*Berlin. Klin. Wchnschr.*, 39 (1902), No. 38, pp. 881-886).—Detailed notes are given on the clinical history and post-mortem examination of human tuberculous patients in which there was apparently good evidence of a primary infection of the alimentary tract. Among 12 children who died of tuberculosis and upon whom post-mortem examinations were made a diagnosis was reached indicating primary alimentary tuberculosis in 2 cases. Inoculation experiments were made on calves and cows with material obtained from some of these cases. It was found that the bacilli thus obtained were pathogenic for calves, being in some cases exceedingly virulent. In all, 5 cases of tuberculosis in man furnished material for inoculation of calves, and a great difference in the virulence of the bacilli was noted, ranging from completely nonvirulent to very virulent forms. It was observed that the virulence of the bacilli obtained from these human tuberculous patients varied according to the age of the patients, being gradually weakened in the older patients. The possibility is suggested of an attenuating influence of the human organism which manifests itself in gradually weakening the virulence of tubercle bacilli.

The transmissibility of bovine tuberculosis to man, KÖHLER (*Deut. Med. Wchnschr.*, 28 (1902), No. 45, pp. 800-804).—The recent literature relating to this controversy is critically discussed by the author. It is argued that a majority of cases of tuberculosis in man are due to infection from other human beings rather than from the products of tuberculous animals. The statistics quoted by the author are believed to furnish proof of this proposition. It is not thought desirable, however, to abandon all the safeguards in protecting man from possible infection from animals, but it is urged that the chief attention be given to preventing the spread of tuberculosis from one human being to another.

Tuberculous infection through the alimentary tract, A. HELLER (*Deut. Med. Wchnschr.*, 28 (1902), No. 39, pp. 696, 697).—Brief notes are given on a number of cases in which man has apparently become infected with tuberculous virus of bovine origin, and statistics are presented showing the proportion of such cases. Detailed notes are given on one case of intestinal tuberculosis in a 13-year-old boy, which was believed to be unexplainable except on the basis of infection through tuberculous products. The author states, however, that this case is not unexceptionable, since we must consider that tubercle bacilli of human origin may readily be ingested into the alimentary tract along with filth which may be present on the hands, especially of children.

Inoculation tuberculosis, O. LASSAR (*Deut. Med. Wchnschr.*, 28 (1902), No. 40, pp. 716-718).—Among 108,000 patients which came under the attention of the author during the past 10 years, 34 are believed by him to be undoubted cases of inoculation tuberculosis. These cases were chiefly veterinarians, meat stampers, butchers,

and meat dealers. Details are given concerning the history of a few of these cases. While among the patients which were examined by the author less than 0.03 per cent were affected with cutaneous tuberculosis, this is believed nevertheless to indicate the comparatively serious danger from infection by bovine tuberculosis in skin wounds.

Pearl disease and human tuberculosis, M. WOLFF (*Deut. Med. Wchnschr.*, 28 (1902), No. 32, pp. 566-570).—This article is of a controversial nature. The author argues from the results of experiments and from observations that bovine tuberculosis may be transmitted to man. Detailed notes are given on a case of primary alimentary tuberculosis of man which can only be explained as the result of infection from tuberculous animal products. A number of experiments were made in inoculating animals with material obtained from this and other cases. As a result of these inoculations and post-mortem examinations it is argued that tuberculosis may appear in man and cattle under the same form, and that the 2 diseases are identical. It is urged, therefore, that all measures which have been adopted for preventing the spread of tuberculosis by means of animal products should be rigidly adhered to.

What is pearl disease? J. ORTH (*Berlin. Klin. Wchnschr.*, 39 (1902), No. 34, pp. 793-798).—Brief notes are given on the different views which have been held regarding the nature of pearl disease and its relationship to human tuberculosis. A number of experiments were conducted in which experimental animals were inoculated with tuberculous material of human origin and the material obtained from these animals was then used in testing the susceptibility of calves, hogs, and goats. Three of each of these animals were used in the experiments. Among the calves, 2 showed only local changes while 1 exhibited considerable evidence of generalized tuberculosis, including swelling of the mesenteric, portal, and cardiac lymphatic glands. Similar results were obtained with the hogs, of which 2 were only slightly infected, while 1 exhibited considerable tuberculous alterations. All three of the goats became affected with generalized tuberculosis. The author concludes, therefore, that tubercle bacilli of human origin may be so increased in virulence as to become pathogenic for domesticated animals.

Tuberculosis of the transversely striated muscles, S. SALTICOW (*Contrib. Allg. Path. u. Path. Anat.*, 13 (1902), No. 18, pp. 715-718).—A brief review is given of the literature relating to the subject of the behavior of the musculature toward infection with tuberculosis. The author made a number of experiments on rabbits. The animals were inoculated intravenously with tubercle bacilli and the tubercles which developed as a result of this infection were carefully studied with regard to histological details. The muscles were examined at various periods ranging from 2 to 25 days after the inoculation. Detailed notes are given on the histological features and changes observed in the muscles. The tubercles appeared to arise first in the walls of the blood vessels, and were at first formed by the cells of these walls. Later, muscle and other tissues seemed to be concerned in the formation of the tubercles. It was not until 12 days after inoculation that any proliferation of muscle cells could be observed in the neighborhood of the forming tubercles.

Combating bovine tuberculosis in Norway, O. MALM (*Tidsskr. Norske Landbr.*, 9 (1902), No. 10, pp. 455-467).—An appropriation was made for the study of the diagnostic value of tuberculin in 1891, and in 1895 systematic work on the problem of bovine tuberculosis in Norway was begun. Extensive tuberculin tests were made between this date and 1901 and the results of these tests were summarized. It was found that the number of infected animals varied from 3.3 to 8.4 per cent. The smallest infestation was found in younger animals, while the more extensive infestation was observed in animals 5 years or more old. It is believed that a successful fight can be waged against the bovine tuberculosis in Norway by means of thorough tuberculin tests and through the cooperation of veterinarians, progressive stock farmers, and officials.—F. W. WOLL.

should be put forth to stamp out tuberculosis in cattle, and that milk and tuberculous products should be sterilized before being eaten.

The transmissibility of human tuberculosis to cattle and goats, A. MOELLER (*Deut. Med. Wchnschr.*, 28 (1902), No. 40, pp. 718, 719).—The author conducted a number of experiments, during which attempts were made to inoculate calves with human tubercle bacilli by way of the mouth, by intraperitoneal, subcutaneous, and intravenous injections, and by inhalation. All three of the goats became affected with generalized tuberculosis. The author concludes, therefore, that tubercle bacilli of human origin may be so increased in virulence as to become pathogenic for domesticated animals.

Tuberculosis of the transversely striated muscles, S. SALTUKOW (*Centbl. Allg. Path. u. Path. Anat.*, 13 (1902), No. 18, pp. 715-718).—A brief review is given of the literature relating to the subject of the behavior of the musculature toward infection with tuberculosis. The author made a number of experiments on rabbits. The animals were inoculated intravenously with tubercle bacilli and the tubercles which developed as a result of this infection were carefully studied with regard to histological details. The muscles were examined at various periods ranging from 2 to 25 days after the inoculation. Detailed notes are given on the histological features and changes observed in the muscles. The tubercles appeared to arise first in the walls of the blood vessels, and were at first formed by the cells of these walls. Later, muscle and other tissues seemed to be concerned in the formation of the tubercles. It was not until 12 days after inoculation that any proliferation of muscle cells could be observed in the neighborhood of the forming tubercles.

Combating bovine tuberculosis in Norway, O. MALM (*Tidsskr. Norske Landbr.*, 9 (1902), No. 10, pp. 455-467).—An appropriation was made for the study of the diagnostic value of tuberculin in 1891, and in 1895 systematic work on the problem of bovine tuberculosis in Norway was begun. Extensive tuberculin tests were made between this date and 1901 and the results of these tests were summarized. It was found that the number of infected animals varied from 3.3 to 8.4 per cent. The smallest infestation was found in younger animals, while the more extensive infestation was observed in animals 5 years or more old. It is believed that a successful fight can be waged against the bovine tuberculosis in Norway by means of thorough tuberculin tests and through the cooperation of veterinarians, progressive stock farmers, and officials.—F. W. WOLL.

The question of acclimation to tuberculin, BARTELS (*Deut. Thierärztl. Wchnschr.*, 10 (1902), No. 29, pp. 285, 286).—Among 768 steers which had been tested with tuberculin 6 to 7 days previously, 105 reacted, and 97 of these were found to be tuberculous upon post-mortem examination. The author believes that the number of cases which fail to react to tuberculin when tested shortly after a previous injection is much less than has been supposed by some authors. It is believed that where circumstances render it impossible to wait longer in making the test, the second test may be made within 6 to 8 days after the first; the author recommends, however, in all cases where time is not such an important factor that the second test should be made 3 to 4 weeks after the first.

Contribution to von Behring's method of immunizing cattle against tuberculosis, MELDE (*Berlin. Thierärztl. Wchnschr.*, 1902, No. 40, pp. 593-597).—The author presents an outline of the immunization method with which von Behring has been experimenting. The method has been extended and is being put into practice on a larger scale. Experiments are being conducted to further perfect methods for securing tuberculin of known strength. In all, about 3,000 cattle have been tested with the Marburg tuberculin, and it has been found that all animals endured this test without any injurious consequences. Various races and ages of cattle have been tested by the tuberculin and have been subjected to vaccination according to von Behring's method. Up to the present time 175 cattle have been immunized in this manner, and as a rule cattle have been chosen for these experiments from tuberculous herds, so that the immunized animals may be exposed to tuberculous ones. It is believed by the author that the method promises to become exceedingly valuable and further reports on the progress of the experiments are promised.

Experimental investigations on the action of dead tubercle bacilli, C. STERNBERG (*Centrl. Allg. Path. u. Path. Anat.*, 13 (1902), No. 19, pp. 753-778).—The literature of this subject is critically reviewed by the author. Extensive series of experiments were undertaken for the purpose of determining the effect of the presence of dead tubercle bacilli in animal tissues. Tubercle bacilli were obtained from several sources for use in these experiments, and the material used was previously subjected to different processes. The material came from glycerin-agar cultures, bouillon cultures, and pulverized tubercle bacilli. Later a series of experiments was made to determine whether the toxic principles of tubercle bacilli could be readily extracted by ordinary means so as to render dead tubercle bacilli harmless toward animal tissue. Another series of experiments was undertaken to determine the possibility of immunizing animals by means of tuberculin. As a result of these experiments it was found that dead tubercle bacilli in the animal body were capable of producing essentially the same alterations as living bacilli, although to a less extent. The dead bacilli were found to be capable of killing experimental animals and producing typical tubercles with epithelioid and giant cells. Dead tubercle bacilli could be demonstrated in the animal body for a long time after inoculation and were readily stainable. It is believed, therefore, that the active principle of tubercle bacillus is inherent in the bacterial body and is not removed by persistent and repeated sterilization in living steam, but may be extracted by means of alcohol, ether, and chloroform. It was found that the pathogenic action of tubercle bacillus distinguishes it from all other bacilli otherwise resembling it. It is believed that the necrosis of the lungs in pulmonary tuberculosis of animals and man is partly due to the effect of large quantities of dead tubercle bacilli in such situations. It was found that rabbits could be immunized against the effect of dead tubercle bacilli by repeated injections of tuberculin.

The development of the treatment of parturient paresis during the last five years, J. SCHMIDT (*Berlin. Thierärztl. Wchnschr.*, 1902, No. 33, pp. 497-503, fig. 1).—Since the potassic iodid treatment for parturient paresis was introduced by the

author it has been extensively tried in different countries and some of the results of practical experience are brought together in the present article. The author has experimented with pumps for introducing air into the udder in connection with his original treatment. In 140 cases the average length of time between the beginning of treatment and recovery was $6\frac{2}{3}$ hours. It is believed that the use of air hastens recovery in almost all cases. An elaborate discussion is given on the subject of the etiology of this disease. Potassium iodid is known to possess a pronounced antitoxic action and the author believes that the effect of this treatment must be largely due to local action of the chemical in the udder.

On the treatment of parturient paresis, J. SCHMIDT (*Maanedsskr. Dyrlæger*, 14 (1902), No. 5, pp. 192-212).—The author gives a résumé of the literature relating to the treatment of this disease by means of potassic iodid. Notes are also given on the injection of various other substances into the udder, such as warm water, iodine-potassic-iodid, sodium iodid, potassium bromid, etc. It is believed that the most important modification of the potassic iodid treatment which has thus far been proposed is the use of sterilized air. This may be pumped into the udder alone or in combination with and following the potassic-iodid treatment. The chief advantage of the air treatment is that cows recover the normal flow of milk in a comparatively short time.—F. W. WOLL.

Treatment of parturient paresis by iodid of potash, NEVERMANN (*Berlin. Thierärztl. Wehnschr.*, 1902, No. 27, pp. 402, 403).—The Schmidt treatment for this disease has given satisfactory results as a rule but the effectiveness of the treatment has been attributed to various factors. It has recently been found that the treatment is rendered more rapidly effective by forcing considerable quantities of pure air into the udder in connection with the infusion of iodid of potash. The author recommends the introduction of air into the udder after the infusion in cases of parturient paresis.

A new treatment of parturient paresis, E. THIERRY (*Jour. Agricole [Paris]*, 14 (1903), No. 154, pp. 9-15).—Notes are given on the good results recently obtained from the use of filtered air in connection with potassium iodid as a treatment for parturient paresis. It is believed that this disease will in most cases yield to treatment more rapidly when filtered air is used in addition to potassium iodid.

Parturient paresis before parturition and the theory and treatment of this disease by means of filtered air, A. TEETZ (*Berlin. Thierärztl. Wehnschr.*, 1902, No. 32, pp. 474-476).—The author describes a number of cases of this disease which occurred before parturition. Some of the cases were observed before the placenta was loosened, and some of them exhibited an intermittent course. The author believes that parturient paresis is due to excessive anemia of the brain, and that this condition is explained by the unusual flow of blood from other parts of the body to the udder at the beginning of the period of lactation. It is suggested that the introduction of air and the infusion of iodid of potash into the udder might have the effect of forcing out some of the blood from this organ, and thus relieving the cerebral anemia to a certain extent.

Subacute parturient paresis and its treatment with air, A. TEETZ (*Berlin. Thierärztl. Wehnschr.*, 1902, No. 43, pp. 644, 645).—The technique of introducing air into the udder is briefly described. In one case of parturient paresis air was pumped into all 4 teats of a cow affected with this disease. Considerable improvement in the condition of the animal was noted within $\frac{1}{4}$ of an hour, and within 5 hours she was able to get up. A rapid recovery followed this treatment.

Simple treatment of parturient paresis, EVERS (*Berlin. Thierärztl. Wehnschr.*, 1902, No. 32, p. 473, fig. 1).—The author describes an apparatus devised for introducing pure air into the udder of cows affected with parturient paresis. The apparatus consists of a rubber bulb, a metallic cylinder in which cotton batting may be introduced for filtering impurities out of the air, and a suitable smooth needle connected with rubber tubing.

A new instrument for use in the treatment of parturient paresis, NEVERMANN (*Berlin. Thierärztl. Wchnschr.*, 1902, No. 45, pp. 677, 678, fig. 1).—A business firm in Hanover has devised an instrument which may be used in pumping pure filtered air into the udder of cows affected with this disease, and another simple apparatus has been devised by the same firm for administering the potassium iodid. According to the author the instrument is exceedingly convenient and enables the operator to apply the treatment rapidly.

Foot-and-mouth disease and sulphate of iron, A. BOUCHAUD (*Jour. Agr. Prat.*, n. ser., 5 (1903), No. 5, pp. 147-152).—Notes are given on the symptoms and the pathological anatomy of this disease. A number of experiments have been made in the treatment of foot-and-mouth disease with external applications of sulphate of iron. The author repeated these experiments with excellent results. It was found that the spread of the disease could be more effectively checked by this treatment than by any other method. The affected animals were sprayed with a 20 per cent solution of sulphate of iron. The mouth was washed with a 10 per cent solution of the same chemical, and in acute cases a 5 per cent solution was administered internally, to the amount of 2 liters per day for adult animals and 1 liter of a 2 per cent solution for calves. Complete recovery was brought about and the disease was prevented from spreading.

Foot-and-mouth disease and its treatment, G. D'UTRA (*Bol. Agr. São Paulo*, 3. ser., 1902, No. 6, pp. 370-374).—Notes are given on the symptoms and etiology of this disease. The author discusses also the various disinfectants and antiseptic substances which have been used in treating foot-and-mouth disease. Treatment by injections of corrosive sublimate are said to be ineffective.

Study of the diseases included under the name actinomycosis, J. LIGNIÈRES and J. SPRITZ (*Bol. Sec. Fomento [Mexico]*, 2 (1902), Nos. 3, I, pp. 186-200; 4, I, pp. 243-263).—The authors describe the general symptoms and pathological anatomy of actinomycosis. The disease appears under a number of forms, according to the organs which are chiefly affected. The principal forms are those which affect the skin, tongue, pharynx, glands, udder, viscera, and bones. During 1900 and 1901 the disease prevailed to an unusual extent and with great virulence in Argentina. Notes are given on the toxin produced by the pathogenic organism and on the etiology, treatment and serum therapy of this disease. A bacterial organism was found as the cause of the disease, and the term actinobacillosis is used by the authors.

The action of iodine upon actinomyces, SCHMALTZ (*Berlin. Thierärztl. Wchnschr.*, 1902, No. 27, pp. 401, 402).—Attention is called to the difference of opinion which has prevailed between the physicians and veterinarians regarding the effectiveness of iodine treatment in actinomycosis. Brief notes are given on the literature relating to this subject, and an account is presented of an infection with actinomycosis which was suffered by the author. The iodine treatment in this case was ineffective, but a cure was finally brought about by surgical means.

Vaccination for pleuro-pneumonia, LEISTIKOW (*Berlin. Thierärztl. Wchnschr.*, 1902, No. 29, pp. 437-441).—The author discusses the great importance of this disease to veterinarians and cattle raisers. Notes are given on the method of vaccination which has proved quite effective in preventing the spread of this disease. The effects of this vaccination has not been scientifically determined. It is purely an empirical method. Vaccination, however, is considered as exceedingly valuable, and it has contributed greatly to the restriction of an outbreak of this disease.

A study of the bacteriology of pyelonephritis of cattle, LIÉNAUX and ZWAENEPOEL (*Ann. Med. Vet.*, 51 (1902), No. 9-10, pp. 500-507).—The previous literature on this subject is briefly discussed. The authors conducted experiments with the bacillus of Preisz for the purpose of determining whether this organism was the specific cause of pyelonephritis. During the experiments it was found that the

disease was not produced by this organism—merely a local inflammation resulted, without the characteristic symptoms of pyelonephritis.

The therapeutic use of tannoform in intestinal diseases of calves, SCHÜNHOF (Berlin. *Thierärztl. Wehnschr.*, 1902, No. 45, pp. 678, 679).—In the author's practice tannoform combined with calomel has given excellent results in the treatment of diarrhea and other intestinal disturbances in calves. The mixture is prepared so as to contain 1 part of calomel to 100 parts of tannoform.

The treatment of green diarrhea of calves, G. CARLE (*Jour. Agr. Prat., n. ser.*, 5 (1903), No. 4, p. 109).—Considerable success has been had in treating certain intestinal disturbances of children with gelatin. The effectiveness of this treatment is supposed to depend on the power of gelatin to protect the walls of the stomach and intestines against the harmful effects of certain bacteria and toxic products. In the treatment of diarrhea in calves promising results have been obtained by this method. Further experiments will be made.

Coccidiosis of sheep, and the parasitic organism, G. MOUSSU and G. MAROTEL (*Arch. Parasit.*, 6 (1902), No. 1, pp. 82-98, figs. 10).—The authors describe in considerable detail the morphological characters of the protozoan organism which causes coccidiosis. Notes are also given on the pathological anatomy of this disease. The organism in question is often found in sheep also infested with palisade worms, and the lesions caused by the protozoan parasite are frequently attributed to the palisade worms. The organism of coccidiosis is believed by the authors to differ from *Coccidium zürni* and other related species of this genus. It is described as new, under the name *Coccidium faurei*.

Some pig diseases (*Jour. Jamaica Agr. Soc.*, 7 (1903), No. 1, pp. 22, 23).—Brief notes on hog cholera and swine plague.

Swine erysipelas, M. TEMPEL (*Deut. Thierärztl. Wehnschr.*, 10 (1902), No. 52, p. 793).—The author reports finding endocarditis as the immediate cause of death in hogs which had completely recovered from urticaria. It is believed, therefore, that urticaria belongs etiologically with swine erysipelas and that valvular endocarditis may appear in young hogs within 8 weeks after recovery from a case of swine erysipelas.

Recent results in combating swine plague, SCHREIBER (*Berlin. Thierärztl. Wehnschr.*, 1902, No. 48, pp. 749-755).—The history of the development of methods for obtaining polyvalent sera in the treatment of infectious swine diseases is presented in considerable detail. The article is largely of a controversial nature. It is argued that any serum, in order to possess polyvalent action, must be calculated to operate not only against bacteria and other toxins, but also against local toxins formed in the animal tissues during the progress of the disease.

A pyogenic micro-organism in the hog, W. GRIPS (*Inaug. Diss., Univ. Giessen* [1902], pp. 33).—The author found fibrous deposits and abscesses in the peritoneum and serous lining of the thorax of hogs. In these abscesses a bacillus was found which is described as new, under the name *B. pyogenes suis*. The suppuration processes show a strong tendency to encapsulation. The pus is of a thick consistency without disagreeable odor and of a greenish color, and the bacillus which is considered as a cause of the suppuration is not always found alone, but is frequently associated with other bacteria. The organism is pathogenic for rabbits and mice when injected in comparatively large quantities. It gains entrance to hogs through various skin wounds, through the air passages and mucous membranes of the mouth and pharynx.

Septicemic brown neck of hogs, GRAFFUNDER and SCHREIBER (*Deut. Thierärztl. Wehnschr.*, 10 (1902) No. 50, pp. 471-473).—The author describes an outbreak of a peculiar septicemic disease among pigs 6 to 8 months old. These pigs were allowed to run in woodland pasture. The symptoms were disturbances of the general condition, dis-

inclination to move, reddening and swelling of the mucous membranes of the head, salivation, excessive swelling of the neck, especially in the region of the larynx, and coughing. From post-mortem examination it was found that extensive series of infiltration had taken place in the musculature of the head and neck and as far back as the chest. The submaxillary and retropharyngeal lymphatic glands were enormously swollen. Ovoid bacteria which stained in a bipolar manner were found in streak cultures made from material obtained from these cases. These organisms were first suspected of being anthrax bacilli. It was later found, however, that the hogs had eaten the carcass of a steer which probably died of rinderpest. The author believes that the bacilli found in the hogs and which closely resemble the necrosis bacillus, probably made their way into the hogs in connection with the meat of the diseased steer. Brief notes are given on other cases of septicemic infection in hogs and other animals for the purpose of comparing known examples with the cases which came under the authors' attention.

On the behavior of the lymphatic apparatus in intestinal ulcerations in hogs, SEILER (*Deut. Thierärztl. Wehnschr.*, 10 (1902), Nos. 36, pp. 345-347; 37, pp. 351-355; 38, pp. 361-364, figs. 2).—The literature of this subject is critically discussed. Special attention is given to an account of the behavior of the lymphatic system in cases of intestinal ulceration in hogs due to the presence of *Esophagostomum venulosum* and as a result of swine plague and hog cholera. A considerable part of the author's work consisted in a study of a series of sections made through such ulcers and preserved and stained by various methods. A hyperplasia and excessive accumulation of white blood corpuscles in the neighborhood of these ulcers were observed in most cases of infestation by the palisade worms. The various stages in the formation of intestinal ulcers in cases of swine plague and hog cholera are described in detail.

Glanders, R. HOTTINGER (*Bol. Agr. São Paulo, 3. ser.*, 1902, No. 7, pp. 435-437).—Brief notes on the post-mortem findings in 4 cases of glanders, together with a discussion of the diagnosis and etiology of this disease and notes on the use of mallein.

Tsetse fly disease in Togo, West Africa, H. ZIEMANN (*Berlin. Klin. Wehnschr.*, 39 (1902), No. 40, pp. 930-936).—The author presents a general account of the etiology of this disease, together with notes on the life history of the blood parasite.

The so-called Borna horse disease, ENDERS (*Berlin. Thierärztl. Wehnschr.*, 1902, No. 44, pp. 653-658).—Notes are given on the etiology, pathogenesis, symptoms, complications, sequelae, and treatment of this disease.

Scratches or grease heel in horses, N. S. MAYO (*Industrialdist.*, 29 (1903), No. 19, p. 301).—Notes are given on the symptoms of this disease and on the frequency of its occurrence in horses. The treatment recommended consists in cleanly surroundings, poulticing affected parts, and the use of antiseptic ointments.

Mammary botryomycosis in the horse, P. USTERHÜSSEL (*Berlin. Thierärztl. Wehnschr.*, 1902, No. 32, pp. 476, 477, figs. 2).—This disease occurs chiefly in horses, while cattle and hogs appear to be only slightly susceptible to it. Brief notes are given on a number of cases which are reported in the literature on this subject, and a detailed history is presented of one case which occurred in the udder, with fatal results.

The origin of aneurysma verminosum equi, A. STICKER (*Deut. Thierärztl. Wehnschr.*, 10 (1902), No. 28, pp. 274-276).—A number of cases of aneurism in horses caused by the presence of *Sclerostomum bidentatum* were examined by the author with special reference to determining the pathological histology of this disease. It was found that the middle coat of the wall of the blood vessels was chiefly affected, and not the inner coat. A number of cases of this disease were investigated and detailed notes are given on the histogenesis of the aneurisms.

A study of the morphology of the blood of the horse, S. H. BURNETT (*Amer. Vet. Rev.*, 26 (1902), No. 4, pp. 311-325, figs. 10).—The objects of the investigation

reported in this thesis were to determine the structure and condition of the blood of healthy horses and of horses which are suffering from various diseases. Notes were given on the technique employed in this investigation and on the size, appearance, and relative proportion of red corpuscles and 5 varieties of leucocytes which were observed, viz, lymphocytes, large mononuclear leucocytes, polynuclear leucocytes, eosinophilous and mast cells. The variations in the number of these elements in different diseases are presented in tabular form.

Observations on rabies in the district of Habelschwerdt, C. WITTLINGER (*Berlin. Thierärztl. Wchuschr.*, 1902, No. 30, pp. 449-453).—A brief historical account is given of rabies in this district and notes are presented on the cases which have been observed in man and animals. A copy is given of the laws which are in force in this district for preventing the spread of the disease.

Antirabies vaccinations in St. Petersburg, V. KRAIOUCHKINE (*Arch. Sci. Biol. [St. Petersburg]*, 9 (1902), No. 3, pp. 337-342).—Statistical notes are given on the number of persons bitten by presumably rabid dogs and other animals, and on the results of antirabies vaccinations. Notes are also presented on the number of animals suspected of being affected with rabies. The mortality among patients treated by the Pasteur method was 0.18 per cent.

Vaccination of dogs for distemper, H. MEYER (*Berlin. Thierärztl. Wchuschr.*, 1902, No. 45, p. 678).—According to the author the antidistemper serum manufactured by the Jenner Institute in London has given excellent results in his practice, in preventing the development of distemper in young dogs.

Alopecia areata pigmentosa in dogs, V. S. TROFIMOV (*Arch. Vet. Nauk, St. Petersburg*, 32 (1902), No. 11, pp. 921-930, pls. 5).—Detailed notes are given on the etiology and pathological histology of this disease.

The action of ticks upon animal blood, P. GRÜTZNER (*Deut. Med. Wchuschr.*, 28 (1902), No. 31, pp. 555, 556).—A study was made of the changes undergone by the blood of dogs in the body of *Ixodes ricinus*. It was found that the oxygen is removed from the arterial blood and that the red blood corpuscles are completely dissolved, thus setting free the coloring matter.

The tapeworms of ruminants, N. KHOLODKOVSKI (*Arch. Parasit.*, 6 (1902), No. 1, pp. 145-148, pl. 1, fig. 1).—Brief anatomical and descriptive notes on certain species of tapeworms which infest ruminants.

Observations on fowl plague, KÜNNEMANN (*Deut. Thierärztl. Wchuschr.*, 10 (1902), Nos. 43, pp. 413-415; 44, pp. 421-424).—Opportunity was had by the author to study a number of outbreaks of fowl plague. It appears that the disease has now been observed in a number of different localities in Germany, and in some of these outbreaks there is no evidence of importation of the fowls from Italy or other localities where the disease was previously known to exist. The symptoms are not very uniform, but the course of the disease is almost always exceedingly short. Death occurred in the majority of cases after 3 or 4 days. Frequently the comb and wattles exhibited a bluish red color after death. Usually an exudate was observed in the body cavity, and the vital organs in almost all cases were affected with more or less serious alterations. The author found it impossible to isolate any micro-organism which could be considered as the pathogenic cause of the disease. This plague is believed to be identical with the disease previously described as cyanolophia. Pigeons were found to be immune. Transmission experiments with ducks also gave negative results. White mice, guinea pigs, and rabbits proved refractory. Chickens, however, are susceptible to inoculation and to infection by way of the alimentary tract. The virus is destroyed by decomposition within a short time, provided the carcasses of affected fowls are opened. In intact carcasses, however, the virus remains virulent for at least 28 days. The virus is only moderately resistant to heat and is readily destroyed by carbolic acid or corrosive sublimate. The author successfully disinfected poultry houses by the use of milk of lime.

Serum therapy in fowl cholera, WILLERDING (*Deut. Thierärztl. Wehnschr.*, 10 (1902), No. 50, pp. 473, 474).—The author conducted a number of experiments for the purpose of testing the value of the Landsberg Septicidin and the fowl cholera serum of Jess and Piorkowski. Neither of these sera was found to have any noticeable effect in protecting healthy fowls against infection from fowl cholera or increasing the resistance of birds which were already infected.

The chicken mite, G. W. HERRICK (*Mississippi Sta. Bul.* 78, pp. 13, figs. 4).—The most favorable conditions for the rapid multiplication of the chicken mite are filth and insufficient illumination of the chicken houses. The author made a number of experiments in the construction of nests and roosts so that these structures could be readily cleaned and illuminated. In combating the chicken mite with direct remedies the author tested the value of a method which consisted in cleaning the houses once every 2 weeks and dusting them with a mixture containing 3 parts of air-slaked lime and 1 part sulphur. This method was quite effective, but the author believes that the insecticide should be applied at least once per week. Good results were obtained from the use of crude petroleum and kerosene. These insecticides were sprayed or rubbed upon the walls of the nests and other structures in the chicken houses. Kerosene was found to be as effective as crude petroleum, but its effects did not persist so long, since it evaporated more rapidly. During the season of the year when dust is not accessible to the hens the author recommends that boxes containing road dust should be provided for them. Badly infested old chicken houses of slight value may be burned and new ones constructed, or they may be disinfected by the remedies already mentioned and the use of boiling water. Poultry houses should not be in connection with barns or stables, and sitting hens should be isolated from the rest of the hens, so as to prevent their infestation by mites.

The incineration in the open field of carcasses affected with anthrax, VOLMER (*Berlin. Thierärztl. Wehnschr.*, 1902, No. 41, pp. 617, 618).—Various material has been used in producing heat for the incineration of anthrax carcasses in the open field, and notes are given on the comparative cost of the process according to these different methods. The author recommends that the incineration be conducted under the direction of officials, so that complete destruction of the carcasses may be secured.

Innocuous disposal of animal carcasses by means of burning, LOTHES and PROFÉ (*Berlin. Thierärztl. Wehnschr.*, 1902, No. 37, pp. 557-560).—A detailed report is given of a number of experiments which were conducted for the purpose of determining the relative effectiveness and cost of various incineration methods for destroying animal carcasses. It is recommended that unusual care be exercised to secure the complete destruction of all carcasses in cases of serious infectious diseases.

American meat inspection, A. ЗАСНОСКЕ (*Deut. Thierärztl. Wehnschr.*, 10 (1902), Nos. 31, pp. 301-304; 32, pp. 309-312).—Attention is called briefly to meat inspection in this country as conducted under the auspices of city, State, and national authority. Detailed notes are given on the method of inspecting meat under the orders of the Bureau of Animal Industry, and on veterinary police work, transportation of animals, and other functions of this Bureau.

TECHNOLOGY.

A study of cider making in France, Germany, and England, with comments and comparisons on American work, W. B. ALWOOD (*U. S. Dept. Agr., Bureau of Chemistry Bul.* 71, pp. 114, pls. 7, figs. 26).—The author visited some of the more important cider-making districts in France, Germany, and England, and describes the methods observed in those countries in the manufacture of cider. Factories are described in some instances as well as the machinery used, and the methods of harvesting the fruit, handling the must, fermenting, clarifying, etc.

Analyses are given of a large number of European and American ciders and a short bibliography of French, German and English works on cider making is appended.

The effects of fermentation upon the composition of cider and vinegar, C. A. BROWNE, JR. (*Jour. Amer. Chem. Soc.*, 25 (1903), No. 1, pp. 16-33, fig. 1, *dgms.* 2).—A 25-gal. cask was filled with the fresh cider of an unknown variety of apples. The cask was stored in a dry, cool cellar from November 15, 1898, to October 13, 1902, and analyzed from time to time to determine the chemical changes which took place. Fermentation was the greatest from the fourth to the seventh week after storing. During fermentation the sucrose and dextrose were completely removed, but a small percentage of levulose remained unaffected owing to the development of acetic acid, which arrests alcoholic fermentation. In the experiment 100 parts of sugar gave an actual yield of 45.4 parts of alcohol, or about 88.8 per cent of the theoretical yield. The loss in weight of the cider during the 169 days of the alcoholic fermentation was about 2.4 per cent. It is pointed out that in cider making a very serious loss in alcohol may result from the development of acetic acid. In the experiment recorded there was a loss of about 0.7 per cent of alcohol formed from sugar by the development of 0.23 per cent of acetic acid. The loss in cider making from this source, it is stated, can be prevented largely by racking off the cider after the main fermentation into other casks and bunging tightly. Since the presence of acetic acid is detrimental to the development of alcohol, the failures reported by farmers in getting the vinegar to "make" when they add fresh cider to old vinegar is accounted for.

In the acetic fermentation 100 parts of alcohol gave an actual yield of 116.3 parts of acetic acid, or 89.2 per cent of the theoretical yield.

The bung of the vinegar cask was left open for 18 months from July, 1900. During this period the weight of the vinegar in the cask decreased 30 per cent. The acetic acid content decreased over 2.5 per cent, due mostly to destructive fermentation caused by *Bacterium xylinum*, or an allied form which had the property of forming cellulose. During the deterioration of the vinegar there occurred a relatively high increase in the percentage of reducing sugar. Upon examination this was found to be caused by the presence of 2 well-defined osazones, one of which after recrystallization melted at 142 to 143°, and therefore corresponded to the phenolformosazone of Fischer.

"As a remedy against deterioration, vinegars intended for storage should be racked off into clean casks, the latter filled full and tightly bunged. Since none of the acetic organisms can thrive without air, their further development is thus prevented, and the loss from destructive fermentation reduced to a minimum."

Analysis of the dried settlings in the vinegar cask gave the following results: Moisture, 4.91 per cent; fat, 1.69 per cent; protein, 20.13 per cent; ash, 2.65 per cent; crude fiber, 5.69 per cent; nitrogen-free extract, 64.93 per cent. Analyses were also made of the ash of apples, cider, and vinegar settlings. These are shown in the following table:

Ash analyses of apples, cider, and vinegar settlings.

	Ash of apples.	Ash of cider.	Ash of settlings.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Potassium oxid.	58.31	60.60	19.94
Ferric oxid and aluminum oxid.	12.26	6.00	19.97
Calcium oxid.	Undetermined.	1.15	4.17
Magnesium oxid.	Undetermined.	Undetermined.	2.22
Phosphoric acid.	12.51	7.12	29.64
Sulphuric acid.	6.87	4.15	.14
Silicic acid.	1.65	1.90	24.23
Undetermined carbonic acid, etc.	8.40	19.08

Notes on vinegar making, E. F. PERNOT (*Oregon Sta. Bul. 73, pp. 8*).—Vinegar was made at the station from undersized and otherwise unsalable prunes. After running the washed and weighed prunes through a homemade machine with spiked rollers which lacerated and tore them, the mass was inoculated with a pure culture of yeast (*Saccharomyces cerevisia*). This caused a strong and rapid fermentation, which broke down the cell walls of the prunes, thus liberating the clear juice, which flowed into a receptacle below the vat. This method of securing the clear liquid was inexpensive and very satisfactory. In all 10,482 lbs. of Italian prunes were used, from which 630 gal. of juice was obtained, or a yield of a little more than 3 gal. of juice per bushel of fruit. The juice was fermented in open barrels. Fermentation was completed in 10 days, when the juice was found to contain 10 per cent alcohol. It was then inoculated with a pure culture of vinegar ferment (*Bacilli pasteurianum*) by floating it on the surface of the liquid by means of pieces of cork weighted so as to bring the culture in contact with the liquid.

The vinegar thus produced was of excellent quality, with a fruity flavor and good body, analyzing 6.89 per cent total solids. The only objection to it was its color, which was that of very dark wine. It was, however, but little darker than imported malt vinegars, which find ready sale in Oregon markets. Experiments are now in progress to see if some method of clarification can be found which will improve the color. The machine used for lacerating the prunes and the vat for fermenting and collecting the juice are described in detail, and a brief discussion given of the principles of vinegar making and of the best ways of making vinegar for the home.

The small vinegar fly (*Drasophila ampelophila*) was allowed to walk over sterile cultural media under control conditions. Wherever its feet touched the media colonies of acetic-acid germs developed. The digestive tract of this fly was also found to contain large numbers of acetic-acid germs which were capable of growth in sterilized cider. It is therefore believed that this fly is of service in inoculating fruit juices with the necessary germs for producing vinegar. They will also, however, carry spores of molds and other organisms which give a bad flavor to vinegar. Therefore, the use of pure cultures of vinegar ferments is advised. The author states that the station can furnish these, upon application, to residents of the State.

Pear vinegar containing 8.89 per cent acetic acid has been made at the station, and apple vinegar which analyzed 6 per cent acetic acid within 4 months from the time the apples were pressed.

The essentials in making good vinegar are thus stated: "The barrels must be free from must and mold, the depth of the liquid should not exceed the surface measure, free air must be continually admitted, an even, warm temperature should be maintained, and, last but not least, the fruit that is used should be free from decay and mold."

Experiments in wine making, H. SCHELLENBERG (*Jahresber. Vers. Stat. u. Schule, Wädenswil, 1899-1902, pp. 44-46*).—Sal ammoniac added to a cask of pear cider at the rate of 20 gm. per hectoliter conduced to a more rapid and complete fermentation of the must than when it was omitted. Pears just beginning to ripen were used. No influence of the sal ammoniac on the taste of the wine could be detected. Apple and pear wines filtered through a cellulose filter kept fresher during storage and were more highly prized than wine clarified by the addition of 60 gm. of gelatin per hectoliter. A variety of sweet apple was gathered for cider when just beginning to ripen. The flesh was still firm and somewhat acid. A given quantity of these apples yielded more juice and produced a better quality of cider than apples of the same kind gathered 3 weeks later when they had become more mellow. Wine that had become flat in drawing off and clarifying was again made drinkable by the addition of carbonic acid.

Composition and determination of differently prepared wines, W. KELLHOFER (*Jahresber. Vers. Stat. u. Schule, Wädenswil, 1899-1902, pp. 99-103*).—Analyses

are given of wines in which juice only was fermented, pulp and juice fermented together, and juice to which sugar and water had been added.

American wines at the Paris Exposition of 1900, their composition and character, H. W. WILEY; with a monograph on the manufacture of wines in California, H. LACHMAN (*U. S. Dept. Agr., Bureau of Chemistry Bul. 72, p. 40, pls. 2*).—An account is given of the judging of American wines at the Paris Exposition, including analyses of those which received awards. The wines examined included 9 samples of sparkling wines, 2 of brandies, 15 of dry white wines, 22 of dry red wines, 9 of sweet white wines, and 9 of sweet red wines. The analyses are much more complete than those recorded of American wines in the earlier bulletin from the Bureau (*E. S. R.*, 12, p. 994), including data on the glycerol content, specific gravity, polarization, content of alcohol, tartaric acid, sulphurous acid, phosphoric acid, potassium sulphate, extract, ash, reducing sugars, total and volatile acids, and nitrogen. The analytical data obtained are compared with the analyses of standard European wines.

In the second part of the bulletin a discussion is given of the methods observed in California in the production of different California wines. A list is given of the varieties of wine grapes grown and the kinds of wine made from each. In addition, such other matters are discussed as harvesting, fermentation, clarification, tasting, bottling, marketing, and type of wines.

Agricultural fermentation industries, E. BOULLANGER (*Industries agricoles de fermentation. Paris: J. B. Baillière & Son, 1903, pp. XII + 466, figs. 66*).—This is a volume of the agricultural encyclopedia published under the direction of G. Wery. It treats of cider making; brewing; preparation of hydromel, brandies, and rum; and distilling.

Musts and wines in distilling, L. LÉVY (*Les mouts et les vins en distillerie. Paris: C. Naud, 1903, pp. IV + 651, figs. 160*).—This book deals with the history of distilling, statistics of the industry, theoretical considerations, the chemistry of the compounds involved in the process, a study of the natural products from which alcohol is prepared, and the technology of the preparation of wines and musts.

The preparation of cherry wine with and without the addition of currants, W. KELHOFFER (*Jahresber. Vers. Stat. u. Schule, Wädenswil, 1899-1902, pp. 95-99*).—An account of the making of wine from cherries alone, cherries to which citric acid and sugar had been added, and from cherries and currants to which water and sugar had been added. In some cases the juice was fermented alone and in others with the flesh, skins, etc., of the fruit. In order to prevent the development of acetic acid in the cherry-currant wine it is advised that fermentation take place in a cool dark cellar at a low temperature.

Annual report on investigations and progress in the manufacture of sugar, J. BOCK (*Jahresber. Zuckerfab., 41 (1901), pp. XII + 374, figs. 48*).—A review for the year 1901 of investigations on the culture and handling of sugar beets and the manufacture of beet sugar.

Cassava as a competitor of maize in the production of starch and allied products, G. ARCHBOLD (*Jour. Soc. Chem. Ind., 28 (1903), No. 2, pp. 63-66, figs. 3*).—A discussion of the yield and characteristics of starch from cassava based mainly upon the work of the Bureau of Chemistry of this Department and an account of the method of manufacture followed in Florida. Cassava yields about 25 per cent of starch which "would easily take the place of corn starch or starch made from other cereals." The general conclusion reached is "that in cassava, when properly cultivated, we have a formidable competitor of maize, owing to its higher yield of starch and glucose per acre, and as not only is its starch and sugar, but also a considerable portion of the fiber, obtained as glucose, thereby producing a much sweeter and finer-flavored product, and better adapted for confectionery, etc., fully 30 per cent of the fresh root being obtained as glucose."

A new method of extracting olive oil, A. FUNARO (*Staz. Sper. Agr. Ital.*, 35 (1902), No. 11-12, pp. 916-921).—A description is given of a method of oil extraction that is said to yield several per cent more oil than that secured by the ordinary process.

Modern American tanning (Chicago: Jacobsen Pub. Co., 1902, pp. 292, pls. 14, figs. 2).—This is a compilation of articles on the manufacture of leather which appeared originally in *Hide and Leather*.

AGRICULTURAL ENGINEERING.

Report of irrigation investigations, Humboldt River Valley, Nevada, J. D. STANNARD (*Nevada Sta. Bul.* 54, pp. 91, pls. 34).—A report is given of observations on the extent and character of irrigation practiced in the valley, irrigation works, crops grown, claims to water and their adjudication, the unit of measurement, and the distribution and more economical use of water are discussed, with suggestions as to the improvement of the system and methods now in vogue.

Eleventh Biennial Report of the State Engineer of Colorado, 1901-2, A. J. McCUNE (*Denver*, 1902, pp. 334, illus.).—This volume is devoted largely to reports from various superintendents of irrigation and water commissioners, crop statistics, and other routine matters, but contains special reports on Drainage and Seepage Measurements, by C. G. Elliott; and The Measurement of Water, by A. L. Fellows (*E. S. R.*, 13, p. 1103).

Irrigation works of India, R. F. PATTERSON (*U. S. Consular Rpts.*, 71 (1903), No. 270, pp. 356-359).—A brief account of these works, including statistics of capital invested, revenues, and area irrigated. The capital outlay to the end of 1900-1901 is given as \$128,181,526, the net revenues \$8,740,016, the area irrigated 13,547,986 acres.

Irrigation in Spain and North Africa, J. BRUNHES (*Thesis, Univ. Paris*, 1902, pp. XVII + 518, figs. 63, maps 7).—This treatise deals with geographical conditions, methods, and organization and is styled a study in human geography. The regions chosen for study are the Spanish Peninsula, Algiers and Tunis, and Egypt. There is added a bibliography of a large number of publications on irrigation used or cited in the preparation of this treatise.

The Nile dams and reservoir, SIR B. BAKER (*Pop. Sci. Mo.*, 62 (1903), No. 6, pp. 550-561, figs. 6).—This is an address given before the Royal Institution of Great Britain.

A self-adjusting weir (*Irrig. Age*, 18 (1903), No. 5, pp. 138, 139, figs. 3).—A brief statement of the claims made for such a device, invented by C. C. Carlisle, assistant State engineer of Wyoming. The principal feature of this weir is a short movable conduit, connected with floats, which moves up and down over the end of a fixed conduit (which is a little smaller in diameter) as the level of the water in the canal rises and falls. The joint between the movable and fixed conduits is sealed with mercury.

On the conversion of a tidal marsh into a meadow, G. BECKER (*Deut. Landw. Presse*, 30 (1903), No. 15, pp. 118, 119).

Recent progress in the field of agricultural machinery (*Fühling's Landw. Ztg.*, 51 (1902), Nos. 11, pp. 410, 411; 12, pp. 450, 451; 13, pp. 488-492; 14, pp. 521-524, figs. 2; 15, pp. 556-559, figs. 2; 16, pp. 601-603, figs. 2; 17, pp. 638-641, figs. 3; 18, pp. 681-683, fig. 1; 19, pp. 725-727, fig. 1; 20, pp. 765-767, figs. 2; 21, pp. 797, 798, fig. 1; 22, pp. 832-835; 23, pp. 871-874, figs. 2; 24, pp. 910-914, figs. 6).—This is a series of articles on this subject by different authors, including H. Puchner, A. Nachtweh, and W. Heerberger. The subjects discussed in these articles include root and straw cutters, harrows and soil levelers, hay-tedder and press, plows, scythe-sharpening machine, hitching device for horse powers, root digger, mowers and reapers, stationary and portable steam engines.

Methods and machines for cultivating the soil, M. RINGELMANN (*Travaux et machines pour la mise en culture des terres*. Paris, 1902, pp. 188, figs. 267).

Test of binders, A. NACHTWEH (*Arb. Dent. Landw. Gesell.*, 1903, No. 79, pp. 68, figs. 64).—Six grain binders of American make are described and tests of the amount and character of work performed by them and of the draft are reported.

Practicability and adaptability of gasoline engines for agricultural conditions, G. TIMBERG (*K. Landt. Akad. Handl. och Tidskr.*, 43 (1903), No. 1, pp. 26-35, figs. 3, dgm. 1).

Note on simple machines for extracting plantain fiber, R. L. PROUDLOCK (*Dept. Land Records and Agr., Madras, Vol. II, Bul. 47, pp. 261-268, figs. 2*).—Attention is called to the possibilities of the common plantain as a fiber plant, and descriptions of 2 types of primitive machines used in the Philippine Islands for extracting the fiber are given.

Measures for the prevention of accidents with agricultural machinery, W. HOFFSTEDT (*K. Landt. Akad. Handl. och Tidskr.*, 43 (1903), No. 1, pp. 14-25, figs. 9).

Proceedings of the Jefferson Memorial and Interstate Good Roads Convention, held at Charlottesville, Va., April 2, 3, and 4, 1902 (*U. S. Dept. Agr., Office of Public Road Inquiries Bul. 25, pp. 60, pls. 5, figs. 3*).

Road construction, L. H. ADAMS (*Wisconsin Sta. Rpt. 1902, pp. 280, 281, pl. 1*).—A brief account is given of the construction of a macadam road on the University of Wisconsin farm.

Silos and silage, C. S. PLUMB (*U. S. Dept. Agr., Farmers' Bul. 32, rev. ed., pp. 30, figs. 6*).—A thorough revision of this bulletin, which has been in large part rewritten.

MISCELLANEOUS.

Fourteenth Annual Report of Connecticut Storrs Station, 1901 (*Connecticut Storrs Sta. Rpt. 1901, pp. 253*).—This includes the organization list of the station, a financial statement for the fiscal year ended June 30, 1901, a report of the director presenting a general review of station work during the year, and miscellaneous articles noted elsewhere.

Fifteenth Annual Report of Georgia Station, 1902 (*Georgia Sta. Rpt. 1902, pp. 251-260*).—This includes the organization list of the station, reports of the commissioner of agriculture and the director on the work of the station during the year, and a financial statement for the fiscal year ended June 30, 1902.

Twentieth Annual Report of New York State Station, 1901 (*New York State Sta. Rpt. 1901, pp. 434*).—This includes the organization list of the station; a financial statement for the year ended September 30, 1901; a list of periodicals received by the station; a meteorological record noted elsewhere; and reprints of circulars of the station on ginseng culture and "red albumen" and of Bulletins 197-211 of the station on the following subjects: The food source of milk fat, with studies on the nutrition of milch cows (*E. S. R.*, 13, p. 781); inspection of feeding stuffs (*E. S. R.*, 13, p. 774); an epidemic of currant anthracnose (*E. S. R.*, 13, p. 758); notes from the botanical department (*E. S. R.*, 13, p. 759); report of analyses of commercial fertilizers for the spring and fall of 1901 (*E. S. R.*, 13, p. 935); San José scale investigations, III (*E. S. R.*, 13, p. 968); a study of enzymes in cheese (*E. S. R.*, 13, p. 1087); report of analyses of Paris green and other insecticides in 1901 (*E. S. R.*, 13, p. 1068); influence of manure upon sugar beets (*E. S. R.*, 13, p. 1042); commercial fertilizers for onions (*E. S. R.*, 13, p. 1047); conditions affecting weight lost by cheese in curing (*E. S. R.*, 13, p. 1088); stable manure and nitrogenous chemical fertilizers for forcing lettuce (*E. S. R.*, 13, p. 1046); treatment for San José scale in orchards—I, orchard fumigation (*E. S. R.*, 13, p. 1064); the immediate effect on milk production of changes in the ration (*E. S. R.*, 14, p. 77); and director's report for 1901 (*E. S. R.*, 14, p. 95).

Twenty-fourth Annual Report of North Carolina Station, 1901 (*North Carolina Sta. Rpt. 1901*, pp. XX+128).—This includes the organization list of the station, general reports on the different lines of station work, a financial statement for the fiscal year ended June 30, 1901, and reprints of Bulletins 175-180 of the station, on the following subjects: Some new species of the genus *Critagus* and notes on some dichotomous *Panicums* (E. S. R., 12, p. 827), the relative values of some nitrogenous fertilizers (E. S. R., 13, p. 122), edible mushrooms of North Carolina (E. S. R., 13, p. 225), the nature of pentosoids and their determination (E. S. R., 13, p. 321), the composition of cotton-seed meal (E. S. R., 13, p. 479), and the sugar beet in North Carolina (E. S. R., 13, p. 446).

Fifteenth Annual Report of Tennessee Station, 1902 (*Tennessee Sta. Rpt. 1902*, pp. 16, figs. 2).—This includes the organization list of the station, departmental reports upon the work of the station during the year, a list of available station publications, and a financial statement for the fiscal year ended June 30, 1902.

Nineteenth Annual Report of Wisconsin Station, 1902 (*Wisconsin Sta. Rpt. 1902*, pp. 302).—This includes the organization list of the station; a report of the director containing a brief description of the new agricultural building, notes on changes in the station staff, brief statements concerning the control of fertilizers and feeding stuffs and other lines of station work, and a list of available station publications; a brief biographical sketch of the late Prof. E. S. Goff; numerous articles abstracted elsewhere; lists of exchanges and acknowledgments; and a financial statement for the fiscal year ended June 30, 1902.

Proceedings of the sixteenth annual convention of the Association of American Agricultural Colleges and Experiment Stations, held at Atlanta, Ga., October 7-9, 1902, edited by A. C. TRUE, W. H. BEAL, and H. C. WHITE (*U. S. Dept. Agr., Office of Experiment Stations Bul. 123*, pp. 144, pls. 2).—For a summary of the proceedings see E. S. R., 14, p. 313.

On the establishment of agricultural experiment stations in Mexico, S. BONANSEA (*Mem. y Rev. Soc. Cient. "Antonio Alzate," 17* (1902), No. 6, pp. 235-249).—An argument in favor of the establishment of such stations and a statement of lines of work they might usefully undertake.

The promotion of agricultural science, W. H. JORDAN (*Proc. Soc. Prom. Agr. Sci. 1902*, pp. 22-33).—This is the presidential address delivered at the twenty-third annual meeting of the Society for the Promotion of Agricultural Science, held at Pittsburg, 1902.

General agriculture, P. DIFFLOTH (*Agriculture générale. Paris: J. B. Baillière & Son, 1903*, pp. XII+416, figs. 102).—This is one volume of the agricultural encyclopedia published under the direction of G. Wery. The subjects discussed are agronomy, including study and analysis of the soil and the relation of the soil to plants; cultivation of the soil, including reclamation, preparation, improvement, distribution of fertilizers and soil amendments, seeding, maintenance, destruction of weeds, harvesting, and preservation of crops; and rotation.

Practical farming and gardening (*Chicago and New York: Rand, McNally & Co., 1902*, pp. 500, figs. 223, chart 1).—This book consists of a series of chapters by different authors, to which are appended extensive lists of publications bearing on the special subjects discussed. In the several articles an attempt has been made to present "a brief but sufficiently comprehensive introduction to modern agricultural practice . . . to give so clear an insight into the essentials of farming under modern conditions as will simplify and illuminate all future reading . . . and to tell the man who wants to read on any given farm topic where he may find the book he wants." The articles included are: Modern Ideas in Soil Treatment and Tillage, by J. J. Edgerton; Field Crops—Their Adaptations and Economic Relations, with Specific Cultural Directions, by J. J. Edgerton; Vegetable Garden and Trucking Crops, by A. T. Erwin; Fruit Culture and Forestry, by L. R. Taft; Important Injurious In-

sects and Diseases Affecting Field and Garden Crops, Fruits, and Shade Trees, by E. S. G. Titus; Selecting and Feeding Farm Animals for Profit, by H. W. Mumford; Beef Making, by L. H. Kerrick; Feeding Native Cattle for Beef, by J. P. Stevenson; Feeding Range Cattle for Beef, by D. Rankin; Diseases of Farm Animals, by R. A. Craig; The Silo in Modern Agriculture, by F. W. Woll; Making Poultry Pay, by P. H. Jacobs; Handy Rules and Useful Information; and Wholesome Cooking Without Waste.

The book of the farmer, A. BRUTTINI (*Il libro dell'agricoltore*. Milan: Urico Hoepli, 1902, pp. XIX+446, figs. 303).—A popular treatise discussing the soil and plant life; giving directions for the culture of the vine, and all important field, orchard, and garden crops, and describing the raising and feeding of live stock.

The Lupitz estate and its production, C. VIBRANS (*Die Wirtschaft Lupitz und ihre Erträge*. Berlin: Deut. Landw. Gesell., 1902, pp. 33).—The history of the estate is given, together with annual financial statements showing the profits due to the Lupitz system of improving sandy soils.

Recent foreign explorations as bearing on the agricultural development of the Southern States, S. A. KNAPP (*U. S. Dept. Agr., Bureau of Plant Industry Bul. 35, pp. 44, pls. 6, figs. 2*).—This bulletin deals with the method and cost of rice production and the culture of certain other crops in Japan, Ceylon, India, China, and the Philippine Islands. The agricultural conditions and practices in each of the different countries are discussed.

Cooperations among farmers for certain economic ends, M. HANSSON, E. INSULANDER, and G. LEUFVEN (*Meddel. K. Jordbruksdept. [Sweden], 1902, No. 6, pp. 158, maps 3*).—The report contains an historical description and discussions of cooperative enterprises among farmers in the line of creameries, dairy control associations, bull associations, purchasing associations, and egg-shipping associations. Samples of articles of agreement are given in the case of each kind of association.—F. W. WOLL.

Report of the Bureau of Farmers' Institutes, 1900 (*Rpt. New York State Dept. Agr., 8 (1900), IV, pp. 489*).—This contains a list of the farmers' institutes held in 1900, numerous questions asked and answered, and 22 papers presented at the meetings. Among the subjects considered were the following: The Composition and Use of Fertilizers, by L. L. Van Slyke; Butter Making, by G. A. Smith; Barn Construction and Sanitation, by H. E. Cook; Alfalfa in New York, by F. E. Dawley; Temperature and Moisture in Relation to Cheese Ripening, by L. L. Van Slyke; The Evolution of Dairying, by J. Van Wagenen, jr.; The Next Step in the Education of the Farmer, by W. H. Jordan; The Silo and the Material to Fill It, by I. P. Roberts; and The Progress of Dairy Farming in Canada, by J. Robertson.

The officials and laborers of Upper Egypt, H. C. HANSON (*Deut. Landw. Presse, 30 (1903), Nos. 13, pp. 97-100, fig. 6; 15, pp. 117-119, figs. 3*).

Commercial relations of the United States with foreign countries during the year 1902 (*Washington: Department of State, Bureau of Foreign Commerce, 1903, vols. 1, pp. 1225; 2, pp. 989*).

Agricultural and commercial statistics for 1901, B. E. McLIN (*Rpt. Comm. Agr. Florida, 1901 and 1902, pp. 133-217*).—Statistics on the production of field crops, vegetables, fruits, live stock, dairy products, and miscellaneous products for each county in the State and on the imports and exports of Florida.

Agricultural returns for Great Britain, 1902 (*London: Bd. Agr., 1903, pp. VII+33*).—Tables are given showing the total produce and yield per acre of the principal crops in each county of Great Britain with summaries for the United Kingdom.

General index to the reports and bulletins of the experimental farms of the Dominion of Canada, 1887-1901 (*Ottawa, 1902, pp. 194*).

NOTES.

CONNECTICUT STORRS STATION.—At a recent meeting of the board of control L. A. Clinton, who for the past year has been serving as acting director of the station, was made director.

FLORIDA UNIVERSITY.—The State legislature has changed the name of the Florida Agricultural College to University of Florida.

HAWAII STATION.—The station has begun an extensive series of experiments with tomatoes to try to overcome some of the very serious difficulties of growing this vegetable in the Tropics. The experiments include methods of culture, tests of varieties, protection from insects, etc.

ILLINOIS UNIVERSITY AND STATION.—The Illinois general assembly has made an appropriation of \$135,000 per annum for two years for the support of the college of agriculture and experiment station. The appropriation is more than double that for the two preceding years and is distributed as follows: For instruction, equipment, and buildings, \$50,000; live-stock investigations, \$25,000; soil investigations, \$25,000; dairy investigations, \$15,000; horticultural investigations, \$10,000, and corn investigations, \$10,000.

KANSAS STATION.—O. H. Elling, a graduate of the college, has been appointed foreman at the Fort Hays Branch Experiment Station.

MAINE STATION.—Horace W. Britcher, assistant zoologist of the station, died April 30, after a lingering illness. He had just returned from Arizona, where he had gone in the hope that the climate might prove beneficial.

MISSOURI UNIVERSITY AND STATION.—Howard S. Reed, B. A., of the University of Michigan, has been appointed instructor in botany in the university and assistant botanist to the station, and G. S. Reeves, B. S., laboratory assistant in entomology, University of Illinois, has been appointed instructor in entomology in the university and assistant entomologist to the station.

MONTANA STATION.—At a recent meeting of the executive board S. Fortier, the director of the station, was granted one year's leave of absence for the purpose of studying the irrigation conditions in California in connection with the irrigation investigations of this Department.

NEW HAMPSHIRE COLLEGE AND STATION.—H. M. Tucker has resigned his position as superintendent of the farm.

NEW MEXICO COLLEGE AND STATION.—R. F. Hare, assistant chemist, has been placed in charge of the chemical work of the college and station until July 1. The legislature has made an appropriation of \$25,000 for buildings and has increased the tax levy for the support of the college from one-fifth to two-fifths of a mill. Farmers' institute work has recently been organized and institutes held in three localities, with very gratifying results. Experiments at the station in pumping water from a 6-inch well for irrigation and other purposes have been very successful. A 12-inch well is now being sunk for further experiments in pumping, and measuring weirs and a water register for the study of the duty of water have been installed.

CORNELL UNIVERSITY.—T. F. Hunt, dean of the college of agriculture of the Ohio State University, has been elected professor of agronomy.

OHIO STATION.—The station has been provided with a complete outfit for electrotyping and printing, and is now printing its own publications.

RHODE ISLAND COLLEGE AND STATION.—An appropriation of \$3,000 for one year has been made for student labor and for agricultural demonstrations. A laboratory for the study of animal diseases, particularly poultry diseases, is being fitted up by the station, and additions are being made to the poultry plant for the purpose of facilitating studies of the blackhead disease of turkeys.

SOUTH CAROLINA COLLEGE AND STATION.—Committees have been appointed by the board of trustees for the purpose of securing plans for an agricultural building, including a pathological laboratory for the division of botany and bacteriology, and an insectary for the division of entomology, an iron-frame greenhouse, a building for the Young Men's Christian Association, and a gymnasium.

SOUTH DAKOTA STATION.—The work of testing cereals in cooperation with this Department which has been conducted at Mellette for the past two years has been transferred to the substation at Highmore on account of advantages of the latter as regards location and climate. The highest market price (\$7.25 per hundred live weight, shorn) was recently received at Chicago for lambs fed at the station.

WISCONSIN UNIVERSITY.—Charles R. Van Hise, professor of geology, has been elected president of the university. His new duties will begin with the next academic year.

U. S. DEPARTMENT OF AGRICULTURE.—C. B. Simpson, investigator, Division of Entomology, has been appointed entomologist in the Transvaal department of agriculture. The appointment is for three years beginning July 1. E. S. G. Titus has been appointed to fill the vacancy in the Division.

CARNEGIE INSTITUTION.—The first Yearbook of the Carnegie Institution of Washington has recently been issued. It constitutes a volume of over 300 pages and contains an account of the work of the institution for the year 1902. The first part of the volume is devoted to a reproduction of the articles of incorporation and by-laws of the institution, together with the trust deed of Mr. Carnegie, the minutes of the meetings of the incorporators of the institution and of the board of trustees, and the proceedings of the executive committee. The greater part of the volume is occupied with reports of advisory committees who were consulted with regard to problems in various lines of research which might well be encouraged and supported by the Carnegie Institution. The volume contains reports from advisory committees on the following subjects: Economics, botany, physics, geology, geophysics, geography, meteorology, chemistry, astronomy, paleontology, zoology, physiology, anthropology, bibliography, engineering, psychology, history, and mathematics. The lines of work which are recommended by the various advisory committees are much diversified and cover very wide fields of research. In a summary of the plans and methods thus far agreed upon it is stated that it is within the purpose of the Carnegie Institution to encourage any branch of science, but that efforts will be made to secure cooperation with other institutions and to direct the energies of the Carnegie Institution in such manner as not to interfere or compete with the work of other agencies or institutions. It is stated that specific grants will be made for different purposes to individual investigators, and these grants may be used for any purpose necessary for the prosecution of the work undertaken by the different investigators. In the appendix to the volume detailed accounts are presented of a number of proposed biological explorations and investigations on a large scale. These include a biological survey of the Palearctic region, South and Central America, the establishment

of biological experiment stations for studying evolution and other problems, an antarctic expedition, and an investigation of subterranean temperatures. The funds required for all these proposed lines of research would be far in excess of those at the disposal of the institution, and attention will therefore be concentrated upon the selection of certain problems which appear to require immediate assistance.

NATIONAL FARM SCHOOL AT DOYLESTOWN.—The bill relating to this school as finally passed by the Pennsylvania legislature and signed by the governor carried an appropriation of \$10,000 for the biennial period instead of \$15,000 as previously announced. The post-office address of this school is Farm School, Bucks County, Pa.

AMERICAN CHEMICAL SOCIETY.—The Society will hold its twenty-eighth general meeting at Cleveland, Ohio, June 29 and 30, 1903. In the announcement of the meeting the attention of those who will present papers is called to the desirability in most cases of a brief, clear presentation of results rather than technical details which, though very suitable in published papers, are generally out of place in meetings of this kind in which the time available for the presentation of papers is usually limited.

MISCELLANEOUS.—The legislature of Hawaii at its recent regular session provided for a reorganization of the office of the commissioner of agriculture by placing the duties of that office under the control of a nonsalaried board of five commissioners. The new law defines the duties of the board and provides for the enforcement of its regulations. Under the new arrangement particular attention of the board is given to forestry, entomology, and inspection of plants, fruits, etc., to prevent the admission of injurious fungi and insects. For this work paid superintendents and assistants are provided. For the development of general agriculture, cooperation with the experiment station established by this Department is to be sought, and such an arrangement can hardly fail to be of benefit to the station as well as to the islands.

The Connecticut Agricultural College announces a summer school for teachers and others in nature and country life, to be held at Storrs, Conn., from July 6 to 28. The work will consist of lectures and field and laboratory studies. The subjects offered for instruction include birds, insects, geology, botany, landscape gardening, forestry, flower growing, soils, farm crops, fruits, vegetable growing, farm animals, stock feeding, milk production, poultry, natural science, and the pedagogy of nature study.

The first edition of *El Cafetal*, a monthly review devoted exclusively to the coffee industry in all its branches, appeared April 1. It is a journal of about 20 pages and is published in Spanish at the Produce Exchange Building, New York, in the interests of coffee producers of the Latin-American countries.

The first number of a new veterinary periodical entitled *Fortschritte der Veterinär-Hygiene* was issued in April of the present year. The ground which will be covered by this periodical includes the whole field of veterinary hygiene, and the periodical will include original articles and abstracts.

Dr. Michael Woronin, the well-known Russian botanist, died in St. Petersburg March 5, 1903, in his sixty-fifth year.

EXPERIMENT STATION RECORD.

VOL. XIV.

JULY, 1903.

No. 11.

The plans for the exhibit of the colleges of agriculture and mechanic arts and the experiment stations at St. Louis next year are now taking sufficiently definite form so that an outline of the proposed exhibit can be given. The general committee has held two meetings, one on the grounds at St. Louis, and the subcommittees have been industriously working out the details of their respective parts. At a meeting of the full committee at Columbus June 20 the general plan and many of the details were formally adopted.

The exhibit will aim to show in a quite comprehensive way the methods and results of work of the colleges and stations, with a view to bringing out the characteristic features which distinguish them from other educational and research institutions, and the extent and scope of their fields. To this end the exhibit will be a collective one, in the sense that the work of the various institutions will be shown collectively rather than in the form of individual exhibits by the different colleges. It will thus be essentially a cooperative enterprise between the various institutions, acting through the committee appointed to prepare the exhibit, and will be made up quite largely of materials furnished by the different colleges and stations, classified and arranged so as to form a well-rounded whole. This will prevent duplication, but will in no way detract from the credit given individual institutions.

Strictly speaking, the appropriation of \$100,000 made by Congress can not be used for the purchase of exhibits as such, but is intended to pay the expense of assembling, installation, and care. A liberal construction of the act, however, will allow the purchase of certain materials and objects used in the preparation of an exhibit to supplement the assistance given by the institutions themselves, but the amount which it has been possible to set aside for this purpose is relatively small. The committee has already found from its estimates of the necessary expenses for cases, fitting up of laboratories and other features upon the space; the installation and maintenance of the exhibit, the packing and transportation of the materials to and from St. Louis, and other necessary items, that it will be necessary to practice economy in order to accomplish what is desired.

The location decided upon is in the Palace of Education, where a very desirable space, comprising about 11,500 square feet, has been assigned to the committee by the exposition authorities. This space occupies a conspicuous position in the building, is well lighted, and is adjacent to the educational exhibits of several foreign countries. The division of space as agreed upon gives about 4,000 square feet to mechanic arts, 6,000 square feet to agriculture, and 450 square feet each to the Bureau of Education and the Office of Experiment Stations.

The plans for mechanic arts have not yet been worked out in detail by the subcommittees in charge. In general, the main divisions of this portion will be civil, mechanical, electrical, mining and chemical engineering; architecture, drawing and shop practice; and industrial and domestic arts, the latter to include domestic science. A canvass has been made of the colleges, which has indicated a large amount of material to be available in most of these lines.

The general divisions of the agricultural portion of the exhibit will be plant production, including horticulture and forestry; zootechny, including animal husbandry and veterinary science; agrotechny, including dairying and other lines of agricultural manufactures, such as sugar making, wine making, canning, meat products, tobacco, etc.; rural engineering; and rural economics. There will be no separation of the instruction work from the experiment station work, as was done at Chicago, but the different lines will be united so as to show their interrelations, and this will frequently avoid duplication. In plant production, for instance, the exhibit will show the materials used for instruction as well as the methods and results of investigation, including the study of plant diseases and injurious insects, the inspection work, the results of plant breeding, etc. There will be a working laboratory for soil physics, showing equipment for both instruction and investigation, with exhibitions of typical soils, standard fertilizing materials, methods of studying the fertilizer needs of soils and plants by means of pot culture, etc.

As illustrating the means of instruction in animal husbandry it is proposed to show a model class room, equipped with the special provisions in the way of models, charts, illustrative material, etc., which experience has suggested as advantageous to this line of instruction. This, it is thought, can be made a novel and attractive feature, and serve to show the progress which has been made in adapting and providing facilities for class-room work. Another section of this exhibit will show the investigation work in the breeding, feeding, and management of animals. This is expected to include a model of the Armsby respiration calorimeter, equipment for digestion work, examples of important lines of feeding work with various kinds of live stock, and methods of breeding, together with some of the results, notably with

poultry. The veterinary science laboratory will likewise include both methods of instruction and of research, and will contain illustrations of typical results of the stations' work in study of animal diseases and their control.

Dairying will constitute a prominent feature in point of space and in variety and character of methods and results presented. There will be a working dairy laboratory, together with a model creamery for purposes of instruction. The results of the stations' work in showing the relation of food to quality of dairy products, the effect of micro-organisms, the curing of cheese, and other work relating to the progress of dairying, will be illustrated by specimens, models, and charts. The important work which has been done in sugar production, both from sugar cane and from the sugar beet, as well as the studies on maple sugar, will be shown in a sugar laboratory, adjacent to which other lines of agricultural manufactures will be illustrated.

The exhibit in rural engineering will include the layout of farms, farm buildings and machinery, irrigation, drainage, and road construction. In connection with the irrigation and drainage exhibits experimental and model systems will be shown, with fields arranged to illustrate different methods of irrigation, drains for removing excess of water, and provided with a pumping plant. This should prove one of the most attractive and instructive features of the whole exhibit, but from its character need not be very expensive.

One controlling idea which has been borne in mind in planning the exhibit has been to provide as many features as possible which would in a measure be self-explanatory and would attract the attention of the passer-by. The experience of the past has shown that objects, models, and exhibits containing some feature in operation are a more successful means of illustration than charts and diagrams, although it is difficult to fully illustrate some lines of station work without the latter. Frequently some feature can be used to attract the attention, which can then be led to a more detailed presentation. Several attendants to act as demonstrators are planned for.

In addition to the exhibit in the Palace of Education, the exposition authorities have agreed to provide a building where the work in animal husbandry, especially in stock judging, can be shown. This will consist of a stock-judging room where the work can actually be carried on with provision for block tests, the cutting up of beef, cooking tests, etc. A considerable sum of money has been set apart by the committee for the purposes of this exhibit outside the education building.

The plans for the preparation of the exhibit include the collaboration of the Office with the central office of the committee. In the case of certain laboratories and parts of the exhibit the assembling of the materials, and in general the method of presentation, will be assigned

to experts, who will act in collaboration with the committee. Definite requests will be made of individual institutions for contributions in their respective specialties.

The exhibit at St. Louis will differ in some respects from any previous exhibit which our colleges and stations have made. The first undertaking of the kind was at Chicago ten years ago on a considerably smaller space. At that time the whole exhibit was placed in the agricultural building. The much smaller exhibits which have been since made at Buffalo, Paris, and Charleston have related very largely to the experiment station work, and have likewise been classed with the agricultural exhibits. The change of location to the education building therefore makes a new departure, the reasons for which may not at once be patent.

There can be little question regarding the desirability of classifying that portion of the exhibit relating to the land-grant colleges in the education building. The stations are legally, and actually for the most part, departments of these colleges; and, furthermore, the experiment station exhibits of the foreign countries will be made in the education building in connection with their educational exhibits.

But there is still another reason. While the work of the experiment station touches agricultural practice on the one hand, and this relationship has been most often emphasized, it also touches agricultural education on the other. It has been referred to as constituting the capstone of agricultural education, and it quite as truly furnishes the foundation for it. Indeed it is on its educational side that the experiment station movement is destined to exert its most profound and permanent influence; for the investigations and experiments of the stations not only provide much material for effective courses of instruction in the theory and art of agriculture, but they also furnish to the farmer the hitherto lacking motive for definite technical education along the lines of his art. This is changing the intellectual attitude of the farmer from conservatism to progressiveness.

The experiment station work in its practical application has already won its way with the farmers of the country, and its utility needs no further demonstration or advertising. But there has been a desire on the part of many to bring out its broader relations and its position in the whole system of agricultural education, which is not so generally realized and appreciated. The St. Louis Exposition has been thought to furnish a good opportunity for enforcing this conception of the stations. The leading purpose of the whole exhibit is to show the strong place which the land-grant colleges and the experiment stations have taken in our educational system. If it can once be made clear and apparent that agriculture has a pedagogic form, then educators

can be looked to to take it up and provide a place for it in the general scheme, from the common school to the higher institutions of learning, and the interest and support of teachers can be invoked.

This result is a most desirable one from the experiment station standpoint. A better educated rural population will be better able to make use of the experiment station work. The highest use of the experiment station must depend upon an educated constituency.

This issue concludes the regular abstract numbers of volume fourteen. Number twelve will, as usual, be devoted to the subject and name index to the current volume. This is now well under way and will be issued as speedily as possible.

The revision of the manuscript of the general index to the first twelve volumes of the record has proved a more formidable and time-consuming task than was anticipated. The work has not been allowed to lag, however, but has been pushed forward unremittingly during the past winter and spring. It is a pleasure to state that this index is now approaching completion and will soon be ready for the printer.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

Improved method for separation and determination of total alkalis in soils, J. H. PETT (*Jour. Amer. Chem. Soc.*, 25 (1903), No. 5, pp. 496-498).—To avoid error due to presence of barium carbonate the official method is modified as follows: "Just previous to evaporating the solution of the chlorids in platinum dishes a few cubic centimeters of an ammonium sulphate solution—75 gm. to the liter—are added. The precipitate is filtered and the filtrate evaporated, as usual, in platinum dishes and ignited. In this way the barium is completely removed at one operation and the alkalis are changed into sulphates, which can be ignited over the full heat of the Bunsen burner without danger of loss through volatilization. . . . After igniting to a red heat about 1 gm. of dry, powdered ammonium carbonate is added to the dish and volatilized, thus breaking up any acid sulphates which may have formed."

The solubility of barium sulphate in ferric chlorid, aluminum chlorid, and magnesium chlorid, G. S. FRAPS (*North Carolina Sta. Rpt.* 1902, pp. 50-52).—The results of tests made by the author at room temperature and compared with results obtained by Fresenius show that barium sulphate is much less soluble in a 10 per cent solution of ferric chlorid or aluminum chlorid than in 10 per cent nitric or hydrochloric acid, but more readily soluble in a 10 per cent solution of ammonium chlorid than in a 10 per cent solution of ferric chlorid or aluminum chlorid. In the presence of barium chlorid barium sulphate was found to be less soluble in ferric chlorid or aluminum chlorid than in 10 or 2.5 per cent solutions of ammonium chlorid, a 2.5 per cent solution of sodium chlorid, nitric acid, or hydrochloric acid.

Methods for the determination of total phosphoric acid and potash in soils, C. B. WILLIAMS (*Jour. Amer. Chem. Soc.*, 25 (1903), No. 5, pp. 491-496).—See E. S. R., 14, p. 630.

The determination of citric-acid-soluble phosphoric acid, R. Woy (*Chem. Ztg.*, 27 (1903), No. 24, pp. 279, 280).—The author briefly reviews recent literature on this subject, especially that tending to show the superiority of his method (E. S. R., 9, p. 321) over that of Böttcher as regards accuracy. Some modifications of the method are described.

The determination of citric-acid-soluble phosphoric acid in Thomas slag, O. BÖTTCHER (*Chem. Ztg.*, 27 (1903), No. 22, pp. 247, 248).—Further studies of the applicability and advantages of the author's preliminary test for silica in slags (E. S. R., 14, p. 834) are reported.

A quick practical method for determining the amount of acid required in the preparation of superphosphates, W. STRZODA (*Chem. Ztg.*, 27 (1903), No. 26, p. 299).—To 20 gm. of the phosphate or fertilizer mixture 30 cc. of crude sulphuric acid about 53° B. is added, the mixture shaken, and allowed to stand $\frac{1}{2}$ hour in a warm place (50 to 80° C.). The volume is made to 1 liter and free acid determined by titration. Knowing the exact strength of the original acid, the results thus obtained furnish data for calculating the acid required for reducing the phosphate.

The determination of nitrogen in nitrates and nitric-acid esters, A. WOHL and O. POPPENBERG (*Ber. Deut. Chem. Gesell.*, 36 (1903), pp. 676-684; *abs. in Chem. Centbl.*, 1903, I, No. 15, p. 893; *Jour. Chem. Soc. London*, 84 (1903), No. 486, II, p. 328).—Nitrogen is determined by decomposing the substance with sulphuric acid and mercury in an exhausted flask, which is thoroughly shaken until the substance is completely dissolved, the pressure in the flask, then being determined by means of a manometer. The most serious source of error, the possible formation of oximes, is overcome by adding chromic acid to the sulphuric acid. Various corrections which should be applied are given.

On the determination of organic nitrogen in the presence of nitric nitrogen, A. QUARTAROLI (*Staz. Sper. Agr. Ital.*, 36 (1903), No. 1, pp. 47-51).—In the method proposed 1 gm. of substance is treated with 10 cc. of formic acid in a flask and 5 cc. of concentrated sulphuric acid is slowly added in the cold with constant stirring, the operation being continued in a Schultze-Tiemann apparatus in the usual way.

A burette and standard solutions convenient for the determination of nitrogen by the Kjeldahl method, A. W. BOSWORTH (*Jour. Amer. Chem. Soc.*, 25 (1903), No. 5, pp. 535-537).—Using 1 gm. of substance for the determination, the distillate is collected in 8 cc. of $\frac{1}{2}$ -normal sulphuric or hydrochloric acid. This is titrated with 14.04-normal alkali, which is run in from a burette graduated in reverse order; that is, the zero point is the lowest mark. This burette is filled at the beginning to the 56.16 cc. mark, and the readings give percentages of nitrogen multiplied by 10.

The estimation of small amounts of carbon monoxid in the air, SPITTA (*Arch. Hyg.*, 46 (1903), No. 3, pp. 284-310, fig. 1).—The method proposed depends upon the oxidation of the carbon monoxid to dioxid in the presence of added hydrogen, by means of palladium heated by an electric current.

The distribution of arsenic in nature, F. GARRIGOU (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 24, pp. 1113-1115).

The determination of sulphur in plants, G. S. FRAPS (*North Carolina Sta. Rpt. 1902*, pp. 42, 43).—Since this article was originally published (*E. S. R.*, 13, p. 916) it has been found more satisfactory, as stated in a note, to substitute calcium acetate for potassium nitrate in the preparation of the ash.

The determination of sulphur and chlorin in plants, G. S. FRAPS (*North Carolina Sta. Rpt. 1902*, pp. 44-49).—This is a less detailed account of the work presented before the Association of Official Agricultural Chemists in 1902 (*E. S. R.*, 14, p. 114), the results of which were in favor of the nitric acid method, modified by the substitution of calcium acetate for potassium nitrate for the determination of total sulphur, and the method of ignition with sodium carbonate for the determination of chlorin, as compared with several other methods.

The sulphur content of some vegetable materials, W. A. WITHERS and G. S. FRAPS (*North Carolina Sta. Rpt. 1902*, pp. 53-58).—Determinations of the sulphur content of a number of vegetable materials are reported. The authors found that the ash of plants contains only a portion of the total sulphur. The ash of cotton-seed meal was found to contain $\frac{1}{6}$, cotton-seed hulls $\frac{1}{5}$, oats $\frac{1}{10}$, cowpeas $\frac{1}{6}$, corn $\frac{1}{50}$, peanuts $\frac{1}{3}$, and tobacco $\frac{4}{5}$ of the total sulphur. The sulphur content was found to be greater than has usually been considered. The sulphur content of an ash is considered no indication of the amount of sulphur in the plant, and conclusions reached by ash analyses as regards the sulphur content of the plant are therefore considered entirely valueless.

The determination of pentosan-free crude fiber, G. S. FRAPS (*North Carolina Sta. Rpt. 1902*, pp. 59-62).—This paper was presented before the Association of Official Agricultural Chemists in 1901 (*E. S. R.*, 13, p. 410). The results of tests

show that the König method yields a fiber practically free from pentosans and requires fewer manipulations and less time than the usual method.

Russian export butter and methods of its examination, I. SHIBOKIKH (*Selsk. Khoz. i Lqesor.*, 208 (1903), Mar., pp. 691-700).—It is stated that Russian butter is considered very unsatisfactory in England. The author believes that this opinion is due to a lack of acquaintance with the composition of the butter and to the preponderating importance attached to the content of volatile fatty acids to the neglect of the content of nonvolatile fatty acids.

The method of determining nonvolatile acids, as elaborated by the author, is described. The fat is saponified in the usual manner and the soap is digested on a water bath with a 10 per cent solution of tartaric acid until the nonvolatile acids rise to the surface as a transparent layer. The water is practically all expelled by heating over a free flame, constant shaking being required to prevent violent bumping. There remains in the flask a crystalline precipitate of potassium acid tartrate, a layer of fatty acids, free tartaric acid, and traces of water. The water is entirely removed by placing the flask for half an hour in the steam drying oven. The flask is cooled in a desiccator and ether is added. The extract, which should be transparent and without flakes, is filtered through a dry filter into a weighed flask, and the ether is driven off on a water bath. Drying to a constant weight is easily accomplished. The weight represents the percentage of nonvolatile acids in the fat.

Analyses of 5 samples of typical export butter are reported. These show a range in the water content of from 10.2 to 10.9 per cent; salt content, 0.8 to 3.0 per cent; nonvolatile acids, 88.2 to 88.9 per cent; insoluble acids, 85.3 to 87.6 per cent; Reichert-Meissl number, 21 to 27.4; saponification equivalent of fat, 216.5 to 229.8; milligrams of potassium hydrate required to saturate 1 gm. of the nonvolatile acids obtained by the author's method, 214 to 220, and 1 gm. of the insoluble acids, 206 to 216; iodine number of fat, 26.5 to 38.6; iodine number of nonvolatile acids, 26.6 to 38.5; iodine number of insoluble acids, 25.5 to 38.9, and the specific gravity of fat, 0.8632 to 0.8662. The low content of volatile acids is attributed to the method of feeding.—P. FIREMAN.

Studies of methods of estimating fat in animal substances, W. GLIKIN (*Arch. Physiol. [Pflüger]*, 95 (1903), No. 3-4, pp. 107-145).—A comparison of the principal methods of estimating fat in animal materials led to the conclusion that it may be most satisfactorily determined by extraction with low-boiling petroleum ether (50 to 60° C.). The lecithin in the extracted fat may be separated by taking advantage of the fact that it is insoluble in acetone.

The estimation of the salicylic acid content of berries and stone fruits, Stüss (*Oesterr. Chem. Ztg.*, 5 (1902), No. 21, p. 488).—The data noted in a paper presented before a meeting of the German Naturalists and Physicians led the author to conclude that salicylic acid was not found unless it had been added.

Some of the constituents of cacao and their determination, J. DEKKER (*Inaug. Diss., Univ. Bern, 1902, pp. 83*).—An investigation of the various chemical methods of determining different constituents of cacao.

Investigations on Chinese rhubarb, K. HEUBERGER (*Inaug. Diss., Univ. Bern, 1902, pp. 62*).—A chemical investigation of the various constituents of rhubarb.

The hydrolysis of crystallized oxyhemoglobin of horses' blood, E. ABDERHALDEN (*Ztschr. Physiol. Chem.*, 37 (1903), No. 5-6, pp. 484-494).—Experiments were undertaken to determine the cleavage products of oxyhemoglobin.

The hydrolysis of crystallized serum albumin of horses' blood, E. ABDERHALDEN (*Ztschr. Physiol. Chem.*, 37 (1903), No. 5-6, pp. 495-498).—A study of the cleavage products of crystallized serum albumin.

The hydrolysis of edestin, E. ABDERHALDEN (*Ztschr. Physiol. Chem.*, 37 (1903), No. 5-6, pp. 499-505).—Experimental data are reported.

The hydrolysis of zein by hydrochloric acid, L. LANGSTEIN (*Ztschr. Physiol.*

Chem., 37 (1903), No. 5-6, pp. 508-512).—A study of the cleavage products obtained when zein is hydrolized with hydrochloric acid.

Tests and reagents, chemical and microscopical, known by their authors' names, together with an index of subjects, A. I. COHN (*New York: John Wiley & Sons; London: Chapman & Hall, Ltd., 1903, pp. III+383*).

Report of the chemists, C. H. JONES and B. O. WHITE (*Vermont Sta. Rpt. 1902, pp. 268-271*).—Analyses of 34 miscellaneous samples, including fertilizing materials, wood ashes, muck, and feeding stuffs are reported.

Report on the progress of physical chemistry and physics during the year 1902, M. RUDOLPH (*Chem. Ztg.*, 27 (1903), No. 28, pp. 319-323).—A review with numerous references to literature.

Proceedings of the nineteenth annual convention of the Association of Official Agricultural Chemists (*U. S. Dept. Agr., Division of Chemistry Bul. 73, pp. 187, pl. 1, figs. 5*).—This account of the proceedings of the meeting held in Washington October 2-4, 1902, is edited by the secretary of the association, H. W. Wiley. For a summary of the proceedings see E. S. R., 14, pp. 107-116. A memoir of the late Robert C. Kedzie, by L. S. Munson, and an article on the determination of glucose by E. Gudeman (E. S. R., 14, p. 224) have been included.

BOTANY.

The variation of reserve carbohydrates in the stem and roots of ligneous plants, LECLERC DU SABLON (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 20, pp. 866-868).—The author has made a study of the sugar and starch which are found in the interior of ligneous plants throughout the course of the year. In order that his results might be comparable, plants of the same age and as nearly as possible the same condition were grown under identical conditions. At intervals of about 40 days specimens were removed, thoroughly washed, and the stems and roots examined for their reserve carbohydrates. The variation observed in the stems and roots of chestnut seedlings is shown in the following table:

Variation in the carbohydrates in the stems and roots of chestnut trees.

Date.	Sugar.		Other carbohydrates.		Total carbohydrates.	
	Stems.	Roots.	Stems.	Roots.	Stems.	Roots.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
January 11.....	4.0	1.9	20.7	25.3	24.7	27.2
February 26.....	4.3	4.7	20.4	21.0	24.7	25.9
March 28.....	2.7	3.3	18.8	21.4	21.5	24.7
May 20.....	2.3	3.1	17.6	16.7	19.9	19.8
June 22.....	2.1	3.6	18.3	18.2	20.4	21.8
July 27.....	2.6	3.6	18.5	20.7	21.1	24.3
September 12.....	2.2	1.8	23.7	28.5	25.9	30.3
October 19.....	2.2	1.6	24.2	27.5	26.4	29.1
November 22.....	3.2	1.1	21.5	27.8	24.7	28.9
December 26.....	3.7	1.9	19.3	25.4	23.0	27.3

From this table it is shown that during the winter, when growth is apparently suspended, the total reserves diminish gradually, and in general the root contains more reserve material than the stem. This difference, however, is more apparent in autumn and winter than in the summer. The roots contained more sugar during the period of active growth, and the stems contained their highest proportion during the resting period of the plant. Pear, peach, quince, and alder trees were examined in a similar way, and the results obtained are comparable with those given above.

A study of the reserve carbohydrates of some palms, E. LIÉNARD (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 15, pp. 593-595).—A study is reported on certain reserve carbohydrates found in the endosperm of a number of palms. The

author finds that of the species studied the reserve material consists of small quantities of reducing sugars, saccharose, mannan, and galactan.

Formation of albumen by the higher plants in the dark. I. SHULOV (*Izv. Moscow Selsk. Khoz. Inst. [Ann. Inst. Agron. Moscou]*, 8 (1902), pt. 4, pp. 410-412).—The experiments of the author were made with beets in glass vessels. In each vessel, provided with sand fertilized with a mixture of nutritive salts (without nitrogen), was planted 1 beet root. After 14 days 4 roots were taken out, 4 more after 24 days, 2 after 34 days, and 1 after 44 days, and the total nitrogen determined by the Kjeldahl method and the albuminoid nitrogen after Stutzer. The results were as follows:

Relation of albuminoid to total nitrogen in plants grown in the dark.

	Roots not sprouted.	Sprouted roots, after—			
		14 days.	24 days.	34 days.	44 days.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Total nitrogen.....	1.255	1.700	1.620	1.495	1.820
Albuminoid nitrogen.....	.560	.805	.820	.880	.945
Proportion of albuminoid to total nitrogen	44.620	47.350	50.620	58.860	51.920

These results seem, in the opinion of the author, to show beyond a doubt the possibility of the formation of albumen by the green plants when growing in the dark.—P. FIREMAN.

The influence of organic materials on the development and structure of certain plants. J. LAURENT (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 20, pp. 870-872).—A report is given of studies with peas, lentils, maize, and rye in which glucose and glycerin were added to the culture solution in which the plants were grown. It was found that if the solutions of glucose and glycerin were isotonic they gave comparable results so far as the development and external characteristics of the plants were concerned. The osmotic pressure not only produced modifications, but each species exercised a specific influence. The diameter of the cells increased with the osmotic pressure of the culture medium, the phenomena being most apparent in the solutions of glycerin where the cells of the corticle parenchyma increased much more rapidly and assumed a nearly spherical form. Solutions of glucose and saccharose in general produced a thickening and lignification of the cells. The glucose was not only used for the growth of the membranes, but also the reserve starch which had accumulated in different parts of the tissues. The reserve materials were found most abundant in those plants grown in cultures containing the glycerin; on the contrary, the lignification was less noticeable and the differentiation of tissues occurred much later. This is particularly true of the ligneous plants by which a great part of the glycerin was absorbed and utilized. In the case of maize, starch was not accumulated either in the roots or the stems and the glycerin was used immediately. In this case the glycerin favored the thickening of the cell membranes and lignification of the tissues.

The germination of pollen in the presence of stigmas. P. P. RICHER (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 16, pp. 634-636).—On account of its possible bearing on the limits of the production of plant hybrids the author made a study of the germination of pollen grains when in the presence of stigmas. A large number of species were examined and it was found that many kinds of pollen which could not be made to germinate either in water or sugar solutions readily sent out their pollen tubes if fragments of stigmas of the same or nearly related species were added to the cultures. While a few exceptions were noted it was only when the stigmas of the same or nearly related species were added that germination took place. From

this fact the author concludes that the stigmas of plants secrete substances which favor the germination of the pollen of related species and prevent that of very dissimilar ones.

Canadian experiments with Nitragin for promoting the growth of legumes, F. T. SHUTT and A. T. CHARRON (*Proc. and Trans. Roy. Soc. Canada*, 2. ser., 6 (1900), Sec. III, pp. 55-70, pls. 2).—A brief review is given of the subject of nitrogen assimilation by leguminous plants, and the efforts that have been made in the preparation of pure cultures of the nitrogen-assimilating organisms are described. The authors conducted a series of experiments at the experimental farm, Ottawa, with Nitragin, using a preparation for clover, horse beans, alfalfa, vetches, and peas. The results with clover, peas, and horse beans are described at considerable length. The experiments, with the exception of the horse beans, were on the whole satisfactory and furnished evidence as to the value of this inoculating material. The experiments with clover and peas invariably gave higher yields for treated plats when compared with those grown in similar soils and under like conditions except as to inoculation. The vitality of the bacteria in the culture medium is the most serious detriment to its use. These organisms are particularly susceptible to temperatures above 100° F. as well as to strong light, and their vitality can not be guaranteed for more than about 6 weeks from the time of preparation. For this reason it is considered doubtful whether the use of Nitragin will ever come into general practice by farmers.

Photosynthesis without living plants, L. MACCHIATI (*Rev. Gén. Bot.*, 15 (1903), No. 169, pp. 20-25, figs. 2).—The author briefly reviews the published results of a number of investigators on the possibility of enzymes being concerned in photosynthesis, after which he describes experiments which seem to indicate that these ferments have an important bearing upon the subject of photosynthesis. After carefully washing leaves in distilled water, a glycerin extract was made which when shaken with benzin gave an amorphous, flocculent precipitate, recognized as the enzyme present in the leaves. At the same time the leaves were washed, and after drying for 3 hours at a temperature of 100° C. were finely powdered, and part of the powder was again extracted with glycerin. This yielded an enzyme similar to that taken from the living leaves. Both the enzymes and the dried, powdered leaves were subjected to experiments to demonstrate their ability to carry on photosynthesis. As a result of numerous experiments the author found that the glycerin extract alone was unable to accomplish any photosynthesis, but the powdered leaves containing the enzyme, either alone or when the glycerin extract was added to them, were able to liberate oxygen forming formaldehyde. These experiments, the author believes, indicate that photosynthesis is due to the presence of a soluble ferment and the chlorophyll acts simply as a chemical screen or a sensitizer.

A preliminary account of this investigation is given in *Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 24, pp. 1128, 1129.

Methods in plant physiology, H. S. REED (*Jour. Appl. Micros. and Lab. Methods*, 5 (1902), Nos. 10, pp. 2004-2006; 11, pp. 2045-2048; 12, pp. 2084, 2085; 6 (1903), Nos. 1, pp. 2127-2129; 2, pp. 2174-2176; 3, pp. 2231-2234, figs. 10).—The author gives directions for a number of experiments in laboratory investigations on plant nutrition, osmosis, transpiration, photosynthesis, enzymes, etc.

Phyllobiology, A. HANSGIRG (*Phyllobiologie*. Leipzig: Borntraeeger Bros., 1903, pp. XIV+486, figs. 40).—In this volume the author gives the results of many years' observations on the biological phenomena which are associated with leaves of deciduous plants. The special modifications and adaptations of the leaves of 61 families of plants are described, and their grouping according to ecological types is discussed. The various protective adaptations of young leaves, leaves of seedlings, etc., are treated in a separate chapter.

Reports of Danish experiment stations for plant culture during 1900 and 1901 (*Tidsskr. Landbr. Planteavl*, 8 (1902), pp. 194-222; 9 (1902), pp. 141-164).—

Reports of investigations conducted at the State experiment stations at Vester Hassing, Askov, Tystofte, and Lyngby.

FERMENTATION—BACTERIOLOGY.

Further studies on nitrogen-assimilating bacteria, GERLACH and VOGEL (*Centbl. Bakt. u. Par., 2. Abt., 9 (1902), Nos. 22-23, pp. 817-821; 24, pp. 881-892*).—Experiments are described with *Azotobacter chroococcum* in cultures containing varying amounts of grape sugar. The authors and others had previously shown the possibility of nitrogen assimilation by this and other organisms when grown in nutrient media containing the proper carbohydrates. In the experiments here reported from 1 to 15 gm. of grape sugar were added to each liter of culture medium and after 5 weeks' growth of the organism the nitrogen content was determined by the Kjeldahl method. Uniformly increasing gains are reported for each culture up to the one receiving 12 gm. of grape sugar. Beyond this amount there was a decided falling off in the nitrogen increase. The amount of nitrogen taken from the air by these cultures varied from 7.4 mg. to 127.9 mg. per liter of media. When cultures were used to inoculate soils in which oats, mustard, and carrots were grown there was no gain in the total nitrogen even when cultures were employed that had shown active nitrogen assimilation in the laboratory. In no case was the condition of the plants improved by the inoculation, but in a number of instances decided losses were observed. These experiments were repeated several times in all, 60 pots and 3 different soils being employed.

Some recent investigations in nitrogen assimilation by bacteria without symbiosis, J. VOGEL (*Fühling's Landw. Ztg., 52 (1903), Nos. 5, pp. 178-180; 6, pp. 213-220*).—The results of pot and field tests of the so-called nitrogen assimilating bacteria which do not live symbiotically, particularly of *Azotobacter chroococcum*, are reported. Comparisons are made of the yield, dry matter, and nitrogen content of oats, mustard, and carrots grown in pots and in the field, the soil in each case having received the same kind of complete fertilizer. The effects of inoculating with pure cultures, adding grape sugar to the soils, and the presence of a comparatively large amount of nitrate of soda, were compared. In the pot experiments with oats and mustard increases were noted for the inoculated series, although those pots receiving nitrate of soda gave the largest yields. When subjected to field conditions all inoculated plats gave less yields of dry matter and nitrogen than the uninoculated. In this case the author states that inoculation seemed to have exerted an injurious influence upon the product.

Concerning the specific identity of the tubercle bacteria of the Leguminosæ and the agricultural importance of this subject, H. BUILETT (*Habilschr. Friedrichs-Universität Halle, 1902, pp. 55; also Centbl. Bakt. u. Par., 2. Abt., 9 (1902), Nos. 5, pp. 148-153; 6-7, pp. 226-240; 8, pp. 273-285*).—A discussion is given of the relation of tubercle bacteria to leguminous plants and their function in the assimilation of free atmospheric nitrogen. The author reviews the publications of a number of investigators on this subject and gives the results of his studies in which he claims that the bacteria of the root tubercles which are found on many leguminous plants are all identical with *Bacillus radicicola* of Beijerinck. From the root tubercles of some leguminous plants there were found bacteria which seemed to be very much specialized, but this specialization does not extend to differences that may be regarded as specific. The usefulness of bacteria for inoculating purposes is demonstrated, but it is thought to be confined within rather narrow limits. There does not yet appear to be any pure culture preparation that is entirely trustworthy, and on this account the author recommends recourse to soil inoculations to supply the required organism.

A contribution to the Alinit question, S. SEVERIN (*Centbl. Bakt. u. Par.*, 2. Abt., 9 (1902), Nos. 19, pp. 712-720; 20, pp. 746-756).—The results of cultures of various forms of Alinit bacteria, in which 2 well-marked varieties of *Bacillus ellenbachensis*, *B. megatherium*, and *B. subtilis* were grown in various media, are given. The author believes these organisms are specifically distinct, and points out some of their most marked differences. The results of culture experiments with commercial Alinit for oats are given in which negative results were obtained.

Bacteria in the soil, B. H. BUXTON (*Jour. Appl. Micros. and Lab. Methods*, 5 (1902), No. 9, pp. 1975-1980, figs. 5).—A description is given of methods for separating soil bacteria, their cultivation, and experiments with cultures of bacteria grown upon alfalfa. The article details methods for class demonstration, particularly of the nitrogen-assimilating bacteria.

Photobacteria in chlorophyll investigations, M. W. BEIJERINCK (*Proc. Soc. Sci. Koninkl. Akad. Wetensch. Amsterdam*, 1902, IV, pp. 45-49).—The value of photobacteria as indicators in investigations of chlorophyll functions is pointed out.

Pseudomonas fragariæ, a bacterium causing a strawberry-like odor, T. GRUBER (*Centbl. Bakt. u. Par.*, 2. Abt., 9 (1902), No. 19, pp. 705-712, pls. 2).—A description is given of a species of bacteria which was isolated from fodder beets and cultivated upon various media. The organism produces a very pronounced strawberry-like odor, from which fact it derives its name.

The bacterial flora of the acid fermentation of some foods and condiments, R. WEISS (*Arb. Bakt. Inst. Hochschule, Karlsruhe*, 2 (1902), p. 165; abs. in *Centbl. Bakt. u. Par.*, 2. Abt., 9 (1902), No. 22-23, pp. 844, 845).—The results of extensive studies of various plant and animal foods which have undergone fermentation are given. Particular attention is paid to the bacteria concerned in this fermentation, and 16 well known and 49 new species of bacteria were described. The new species, a list of which is given in the abstract, are fully described in the original publication.

Luminous bacteria, J. E. BARNARD and A. MACFADYEN (*Ann. Bot.*, 16 (1902), No. 64, pp. 587, 588).—An abstract is given of a paper read before the British Association for the Advancement of Science at its meeting in 1902, in which an account is given of experiments conducted on luminous bacteria. The authors have found that the phosphorescence produced by various dead objects, such as fish, etc., is due to bacterial forms of life. The bacteria require rather particular and exact conditions in order to exhibit their luminous properties. They must have a suitable nutrient medium containing the proper proportions of various salts. Luminosity on the part of the bacteria appears to be a function of the living cell, and can be readily disturbed by any process which interferes with its vitality. Free oxygen is essential but in the absence of oxygen the organisms continue to live but are nonluminous. The process of lumination is evidently a vital one and is the result of active oxidation occurring within the cell.

The light produced by these organisms was examined with a spectrum and it was found that the spectrum of none of the luminous organisms extended to the red rays, and it may be assumed that there is no heat given off by them. An exposure to the temperature of liquid air did not destroy the luminosity of the organisms, and when triturated at the temperature of liquid air the luminous bacteria were broken up in such a manner as to cease to give off light.

Concerning the mechanism of agglutination, R. G. SMITH (*Proc. Linn. Soc. New South Wales*, 27 (1902), pt. 1, pp. 66-72).—A review is given of some recent investigations regarding the mechanism of agglutination in bacteria, and attention is called by the author to a previous publication in which it was shown that the function of salts in promoting agglutination is to attack the precipitate on the bacteria, causing it to become agglutinated or flocculated.

International catalogue of scientific literature. R—Bacteriology (*Internat. Cat. Sci. Lit.*, 8 (1902), pp. XIV+314).—This is the first annual issue by the Inter-

national Council of titles of articles and books relating to bacteriology. As mentioned elsewhere (E. S. R., 14, p. 637) it is an outgrowth of the Catalogue of Scientific Papers relating to scientific literature, published by the Royal Society of London. The plan of treatment is similar to that previously described for Botany, an author and subject catalogue being given for the different articles. In all, 2,206 titles are indexed, and for the subject index a decimal system of grouping has been adopted. The value of the catalogue is greatly depreciated by the very evident omission of works by American authors. Only 66 articles and 14 books of authors publishing in the United States during 1901 are listed, and these are distributed through 19 publications. No reference could be found to the work of this Department nor to that of any of the experiment stations, although many contributions were made to bacteriological literature during the year. A saving clause is inserted in the catalogue to the effect that "those portions of the literature of 1901 which are not dealt with in this volume will be included in the volume of Bacteriology which will form a part of the second annual issue of the catalogue." It is to be hoped that a more careful survey of the literature will be given in subsequent volumes.

The practice of industrial fermentation, E. OZARD (*La pratique des fermentations industrielles*. Paris: Masson & Co., 1903, pp. 168, figs. 2).—In this book the author describes the manufacture of alcohol and gives a general account of the various agents used in fermentation. These are considered under the separate headings of yeasts, molds, and diastases, and the advantage accruing from the use of pure cultures is shown. The methods of manufacturing pressed yeast and pure yeasts are described, after which the processes of the fermentation of beets, molasses, potatoes, artichokes, etc., in the preparation for distillation of alcohol, rum, or beer, are described. The subject of the manufacture and use of yeasts in baking is discussed, as well as the use of yeasts in wine making. In the concluding chapter the author describes the process of fermentation in the manufacture of citric acid, gallic acid, and indigo.

Technical mycology: The utilization of micro-organisms in the arts and manufactures, F. LAFAR, trans. by C. T. C. SALTER (*Philadelphia: J. B. Lippincott Co., 1903, Vol. II, pt. 1, pp. VIII+189, figs. 68*).—This is in continuation of Lafar's work on technical mycology, the first volume of which appeared in 1898 (E. S. R., 10, p. 520), and is the first part of the volume treating of Eumycetie fermentation. The general morphology and physiology of the Eumycetes are described, in which the chemical composition, action of mineral nutrients, stimulative influences, presence and action of enzymes in this group of fermenters are discussed in detail. Fermentation by the Zygomycetes is discussed, the morphology, physiology, and fermentation by *Mucor*, *Rhizopus* and related organisms being treated. The use of some of these, such as the Chinese yeasts, *M. rouxii* and *Amylomyces* sp., in the fermentation of various kinds of spirits is described. The concluding portion of the book treats of the Saccharomycetes, the morphology, life history, and anatomy of the yeast cell being fully discussed. With the concluding part of this volume, which is promised by the publishers as soon as the proofs are received from the author, this volume will supplement the first, which treats of the Schizomycetes and their use in the arts and manufactures. The recent advances in applied biology can hardly be appreciated until brought together in some such work as this, and Doctor Lafar has well performed his task.

The general theory of the action of diastases, V. HENRI (*Compt. Rend. Acad. Sci. Paris, 135 (1902), No. 21, pp. 916-919*).—The action of diastases is said in many respects to be similar to that produced by acids acting upon carbohydrates. The author has studied the action of invertin, emulsin, and amylase on various carbohydrates, from which he concludes that when the rapidity of inversion of saccharose is studied it is found that for a given amount of diastase the rate of inversion increases more rapidly than the strength of solution decreases below 0.1 normal, but if the strength of solution is increased beyond 0.1 normal the rate is independent of the concentration of solution. The result is the same for the action of emulsin on

salicin and for amylase on starch or dextrin. The rapidity of inversion for invertin, emulsin, and amylase is proportional to the quantity of the ferment present. The addition of invert sugar to a mixture of saccharose and invertin checks the action of the diastase, and this is believed to be due to the levulose which is contained in the invert sugar. When a certain quantity of saligénin and glucose is added to salicin and emulsin the rapidity of inversion is checked in proportion as the amount of salicin is reduced. In a similar way a mixture of starch and amylase reduces the hydrolysis of starch. If the inversion of saccharose by invertin be carefully followed through, the reaction will be found to obey the same laws as those governing the inversion by acids. In the case of inversion of saccharose the action is more rapid than that by acids, and the hydrolysis of salicin by emulsion takes place more slowly. A theoretical discussion is given of the action of these different ferments.

Proteolytic enzymes in plants, S. H. VINES (*Ann. Bot.*, 17 (1903), No. 65, pp. 237-264).—Since the publication of the author's paper on tryptophane (E. S. R., 14, p. 335) he has continued his observations on the distribution of proteolytic ferments in plants. There appear, from direct and indirect evidence, to be enzymes capable of digesting proteids in certain algæ, some fungi, and various flowering plants. In all cases the process involves the peptonization of the more complex proteids and the proteolysis of the simpler ones. The author's investigations were made with the proteids found normally in the tissues of the plant or upon the Witte-peptone, the object sought being a proteolytic enzym and not a hydrolyzing one. The color test for tryptophane was employed as in the previous investigations, and a large number of fungi, seeds, fruits, latex-bearing plants, stems, leaves, bulbs, tubers, and roots were examined. He found tryptophane present in the expressed juice or watery extracts of banana, melon, ripe cucumber (but not in the green one), vegetable marrow, tomato, onion bulb, and turnip root, but not in the juice of the orange, apple, or grape, nor in the extracts of tubers of potato and Jerusalem artichoke, or green peas, wheat seedlings, or any shoots or leaves examined. The substance has also been found in the milk of cocoanut, in extracts made from bean and pea seedlings, but not in seedlings of maize apart from the seed nor in asparagus, potato, or Jerusalem artichoke shoots, although it was found present in the potato shoots after they had turned green as the result of exposure to light. In the case of the fruits the author believes that tryptophane is certainly associated with the process of ripening and in the case of seedlings with the presence of a supply of reserve proteids.

In summarizing his results, it is claimed that the juices or tissues of various parts of plants act upon proteids so as to give rise to substances having a reaction similar to that of tryptophane. So far the author has been unable to isolate the substance, but he concludes that from the reaction shown by his experiments there is such a chemical substance as tryptophane. The experiments cited above are held to indicate that the vegetable substances showed the effect of proteolysis, which is to be ascribed to a proteolytic enzym contained in the juices or tissues themselves. The distribution of this substance in various orders of plants is briefly summarized, and the author emphasizes the fact that the results given in his paper must be taken as applied only to the particular season of the year during which the experiments were performed.

The growth and reproduction of *Amylomyces rouxii*, J. TURQUET (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 21, pp. 912-915).—The results of investigation on the growth and reproduction of the fungus commonly known as Chinese yeast is reported. The author reports that this fungus possesses not only an asexual method of reproduction, but forms spores in the mycelial filaments. These spores are carried at the ends of the filaments, the mode of production being similar to that in *Mucor*. So far as his cultures are concerned, the author did not observe the formation of any zygosporos. From its mode of growth and asexual reproduction he believes that *Amylomyces rouxii* ought to be included in the genus *Mucor* and placed near *M. racemosus*.

ZOOLOGY.

A biological reconnoissance in the vicinity of Flathead Lake, M. J. ELROD (*Univ. Montana Bul.* 10, pp. 89-182, pls. 30, figs. 3).—This bulletin contains a description of the region about Flathead Lake, together with notes on the animals and plants which are to be found in that locality. Collections of mollusks, insects, and birds have been made and brief notes are given on the species collected. Among the miscellaneous material in the bulletin mention should be made of an account of the Flathead buffalo herd, which is maintained under the same conditions as range cattle and which numbers 220 pure-bred buffalo and 65 half breeds.

The thirty-first annual report of the board of directors of the Zoological Society of Philadelphia, A. E. BROWN (*Philadelphia: Allen, Lane & Scott, 1903, pp. 42*).—An account is given of the mammals, birds, reptiles, and batrachians in the gardens and menagerie, and of the species which were exhibited during the year for the first time. A list is also presented of animals born in the gardens during the period covered by the report, and notes are also given on the additions to the menagerie during the year. C. B. Penrose presents a list of animals which died during the season, together with notes on the causes of their death. A large percentage of these animals died of some form of tuberculosis.

The flame-breasted robin (*Petroeca phænicea*), C. FRENCH (*Jour. Dept. Agr. Victoria, 1 (1902), No. 9, pp. 906, 907, pl. 1*).—A brief discussion of the habits and food of this species of bird, which is considered as strictly insectivorous and recommended for protection.

The house sparrow, J. PERCIVAL (*Jour. Bd. Agr. [London], 9 (1902), No. 3, pp. 338-342*).—Notes are given on the destructive habits of the English sparrow, and this species is compared in its appearance and habits with other related species of sparrows. A scheme of rules is presented suitable for adoption by clubs and societies which may wish to form an organization for the destruction of this bird.

Contributions to the ornithology of São Paulo, H. VON IHERING (*Rev. Mus. Paulista, 5 (1902), pp. 261-330*).—Descriptive notes are given on the various families of birds with special mention of the feeding habits of some important species. A list of the birds which occur in the State of São Paulo is appended to the article.

Necessity of a federal game law and the protection of birds, H. VON IHERING (*Rev. Mus. Paulista, 5 (1902), pp. 238-260*).—Notes are given on the game birds which are at present protected by law at certain seasons of the year, and attention is called to the difficulties in the proper definition of the term "game" so as to exclude birds which should be protected during the whole season.

Destroying prairie dogs and pocket gophers, D. E. LANTZ (*Kansas Sta. Bul. 116, pp. 147-163, figs. 8*).—A copy is given of the State law of Kansas regarding the destruction of prairie dogs and pocket gophers. A circular letter of inquiry was sent out and the answers to this circular furnish the basis for an account of the distribution of these animals. At present it is estimated that the prairie dog villages in the State occupy an area of 2,000,000 acres. Experiments in destroying prairie dogs included the use of traps, fumigation with sulphur fumes and carbon bisulphid, and poisoning with arsenic, corrosive sublimate, barium carbonate, potassium cyanid, and strychnin. The best results were obtained from the use of carbon bisulphid and a proprietary poison formula which contained strychnin. In the destruction of the pocket gopher the author discusses briefly the value of bounties, poisonous gases, trapping, and the use of solid poisons.

Myriapods in the Museum of São Paulo, H. W. BRÜLEMANN (*Rev. Mus. Paulista, 5 (1902), pp. 35-237*).—A monographic account of this group of animals. The author presents an analytical key for the determination of genera and species and gives brief economic notes in connection with the numerous species described, a number of which are new.

METEOROLOGY—CLIMATOLOGY.

Report on international cloud observations. I, Historical, general circulation of the atmosphere. H. H. HILDEBRANDSSON (*Rapport sur les observations internationales des nuages. I, Historique, circulation générale de l'atmosphère. Upsala: Wretman, 1903, pp. 48, pls. 22*).—This report contains a brief historical summary of the theories of Dove, Maury, Ferrel, and Thomson regarding the general circulation of the atmosphere and a review of the results of cloud observations at stations in different parts of the world in their bearing on these theories. The results are shown graphically in a series of charts for stations selected because of their position in certain critical latitudes, for example, San José de Costa Rica; "Square No. 3" (Lat. 0 to 10° N., Long. 20 to 30° W.); Manila; Mauritius; San Fernando and Lisbon; Habana; Lahore, Allahabad, and Calcutta; Kurrachee, Bombay, and Cuttack; Blue Hill; Paris; several in England, Germany, and Denmark; Upsala, and others in Sweden; and places in Norway, Siberia, China, Japan, and other regions.

The author's conclusions, as translated by Professor Ward,^a are as follows: "(1) Above the heat equator and the equatorial calms there is, throughout the year, a current from the east which seems to have very high velocities at great altitudes. (2) Above the trades there is an anti-trade from SW. in the northern, and from NW. in the southern hemisphere. (3) This anti-trade does not extend beyond the polar limit of the trade; it is deflected more and more to the right in the northern, and more and more to the left in the southern hemisphere, and finally becomes a current from the west above the crest of the tropical high pressure belts, where it descends to supply the trades. (4) The districts at the equatorial margin of the trades are partly in the trades and partly in the equatorial calms, according to the season. Above them there is, therefore, an upper monsoon—the anti-trade in winter, and the equatorial current from the east in summer. (5) From the tropical high pressure belts the air pressure on the whole decreases continuously toward the poles, at least to beyond the polar circles. Further, the air of the temperate zone is drawn into a vast 'polar whirl' turning from west to east. This whirling movement seems to be of the same nature as that in an ordinary cyclone. The air of the lower strata approaches the center, while that of the higher strata tends out from the center, and this outward tendency increases with the altitude above sea level as far up as the greatest altitudes from which we have observations. (6) The upper currents of the atmosphere in the temperate zones extend over the tropical high pressure belts, and descend there. (7) The irregularities which are noted at the earth's surface, especially in the regions of the Asian monsoons, as a whole disappear at the lower or intermediate cloud levels. (8) We must entirely abandon the notion of a vertical circulation between tropics and poles which has up to this time been accepted in accordance with the theories of Ferrel and Thomson."

The climate of the Bermuda Islands. A. E. VERRILL (*The Bermuda Islands New Haven, Conn.: Author, 1903, pp. 82-91*).—This article is a part of a comprehensive treatise on the Bermuda Islands, published first in the Transactions of the Connecticut Academy of Arts and Sciences, volume 11. The principal factors determining the character of the climate of Bermuda are its insular position and proximity to the Gulf stream. These prevent extremes of temperature and sudden changes.

"The average temperature during the three winter months and March is from 63 to 66° F.; April, about 65.5°; May, 70.5°; June, 76°; July, 80°; August, 81.7°; September, 80°; October, 73.7°; November, 68°. The average for the year is about 70° F., but ranges from 69.5 to 70.5°. But temperatures as low as 50 to 53° are not uncommon in winter; 42° is rarely reached. It is rarely as high as 87° in summer, but the mean relative humidity, during the summer months, ranges from 80 to

^aScience, n. ser., 17 (1903), No. 436, pp. 752, 753.

91°. . . . The amount of rainfall is large, and it seems to be somewhat larger at Hamilton and Ireland Island than at St. George's. According to Lefroy's tables, covering 11 and 16 years, respectively, it was 54.66 in. at Ireland Island and 48.61 in. at St. George's. The amount near Hamilton in later years usually varied between 58 and 63 in., but in 1898 was only 48.19, and in 1900 it was 67.05 in. The rainfall is usually pretty well distributed throughout the year, but is generally greatest in October and November and least in the summer months, when droughts are not uncommon, but seldom very prolonged. Usually more or less rain falls on from 190 to 207 days; and on at least half of the days of all the months from November to April. But in many cases the rains are mere showers of very brief duration, . . . and in the summer time [the air] is often nearly saturated with moisture, so that it is very oppressive to many persons."

Fogs and hailstorms are rare. Thunderstorms are very common and sometimes violent. High winds are frequent, and destructive hurricanes sometimes occur. Frost, ice, and snow have been observed only a few times in the history of the islands, and no great damage has ever been done by them.

Meteorological observations for 1902 (*Colorado Sta. Rpt. 1902, pp. 153-199, 206-213*).—Tables prepared by R. E. Trimble give daily and monthly summaries of observations during 1902 on temperature, pressure, precipitation, dew point, relative humidity, terrestrial and solar radiation, direction and movement of wind, and occurrence of frost at Fort Collins, Colo.; monthly summaries of similar observations at Rockyford and Cheyenne Wells; and monthly summaries of observations on temperature and precipitation at Long's Peak House near Estes Park (elevation about 9,000 ft.), Gleneyre (elevation about 8,000 ft.), and Cowdrey (formerly Pinkhampton), North Park (elevation 8,400 ft.).

Tables are also given which summarize the monthly and annual precipitation at 7 different places in the State and show the monthly and annual rainfall at Fort Collins for the period from 1872 to 1902 with the normals for that period. The following is a summary of the principal meteorological data reported for Fort Collins: Mean temperature ($\frac{1}{2}$ maximum and $\frac{1}{2}$ minimum), 47.4° F.; maximum, 99.6°, August 1; minimum, -31.4°, January 6; precipitation, 18.43 in.; snowfall, 24.6 in.; mean relative humidity, 67 per cent. The normals for this place are, temperature, 46.6° F.; precipitation, 14.66 in.; mean relative humidity, 65.3 per cent.

The weather during the agricultural year 1901-2; rainfall, temperature, and bright sunshine during 1901 (*Jour. Roy. Agr. Soc. England, 63 (1902), pp. 457-469*).—Observations on temperature, rainfall, sunshine, etc., in Great Britain during 1901 and preceding years are reported and the general weather conditions of the different seasons of 1902 are discussed.

The cereal and other crops of Scotland for 1902, and meteorology of the year relative thereto, A. BUCHAN (*Trans. Highland and Agr. Soc. Scotland, 5. ser., 15 (1903), pp. 319-350*).—A summary is given of observations on pressure, temperature, rainfall, cloudiness, direction of wind, etc., during the year, with notes on the general weather conditions during each month and crop and live stock reports from a number of different localities in Scotland.

Variations in rainfall at Hawkesbury Agricultural College, (C. T. MUSSON (*Agr. Gaz. New South Wales, 14 (1903), No. 4, pp. 345-348, pls. 2*)).—The results of observations with a series of 50 rain gages are reported, which show considerable variations in rainfall over a very small area. "Even in the case of heavy falls the two edges of an acre of ground, of a square form, might receive rain varying by 20 per cent or more. An accumulation of such variations would mean an important factor in the fortunes of the plant inhabitants, which would be emphasized in cases of where plant water requirements were low with heavy rain or high with least rain, or where soils varied much in texture and in relation to water-carrying capacity."

Analysis of red rain of February 22, R. A. EARP (*Nature [London], 67 (1903),*

No. 1740, pp. 414, 415).—Analysis of a red rain which fell on this date at Buckfastleigh, England, is reported, showing 37 gr. of suspended matter per gallon. This suspended matter dried at 100° C. contained 36.4 per cent of organic matter, 45.6 per cent silica, 13.6 per cent alumina and iron oxid, 2.4 per cent magnesia, and 2 per cent of unclassified matter.

AIR—WATER—SOILS.

On the proportion of hydrogen in atmospheric air, A. LEDUC (*Compt. Rend. Acad. Sci. Paris*, 135 (1902), No. 26, pp. 1332, 1333).—A reply to Gautier, reiterating former conclusions.

A further examination of the objections of A. Leduc regarding the proportion of atmospheric hydrogen, A. GAUTIER (*Compt. Rend. Acad. Sci. Paris*, 136 (1903), No. 1, p. 21).

Evaporation, R. E. TRIMBLE (*Colorado Sta. Rpt. 1902*, pp. 205-218).—This is a monthly summary of observations during 16 years (1887-1902) on evaporation from a tank on the station grounds at Fort Collins, Colo.

Water supply and prevention of waste in leading European cities, C. O. JOHNSON (*New York: Merchants' Association of New York*, 1903, pp. 289, figs. 2, *dyns.* 3).—This contains reports on Glasgow, Liverpool, Manchester, Birmingham, London, Paris, Cologne, and Berlin.

New methods and apparatus for sterilizing water, KAUSCH (*Centbl. Bakt. u. Par.*, 1. Abt., 33 (1903), No. 5-6, Ref., pp. 129-136, figs. 7).

Report on artesian wells, L. WOOLMAN (*Geol. Survey New Jersey Rpt. 1902*, pp. 63-95).—A collection of data regarding the artesian wells of the State, especially the southern portion, and a record of the more important wells drilled during 1902.

The sinking of subterranean waters and the disappearance of springs, E. A. MARTEL (*Compt. Rend. Acad. Sci. Paris*, 136 (1903), No. 9, pp. 572-575).

Absorption of ammonia by sea water, J. THOULET (*Compt. Rend. Acad. Sci. Paris*, 136 (1903), No. 7, pp. 477, 478).

The Murray waters (*Agr. Gaz. New South Wales*, 14 (1903), No. 4, pp. 289-309, figs. 31).—This is an extract from the report of the royal commission and deals with the amount and utilization of the waters of the Murray basin.

A preliminary investigation of the soil and water of the Fayoum Province (*Jour. Khediv. Agr. Soc. and School Agr.*, 4 (1902), No. 5, pp. 184-188).—Analyses with reference to alkali content of water, soils, and efflorescences are reported and discussed. Injury from excessive irrigation and defective drainage is pointed out.

On the influence of commercial fertilizers on the water-holding capacity of soils, E. GROSS (*Zschr. Landw. Versuchsw. Oesterr.*, 6 (1903), No. 1, pp. 80-90, fig. 1).—The rate of capillary rise of water in sandy soil poor in humus, loam, and humus loam, in cylinders 1 meter long and 10 mm. in diameter, as affected by potassium sulphate, nitrate of soda, superphosphate, and caustic lime mixed with the soil at the rate of 2 per cent is recorded. The results of duplicate tests are summarized in the following table:

Capillary rise of water in soils treated with different kinds of fertilizing materials.

Fertilizing material.	Sandy soil.		Loam.		Humus loam.	
	Rise of water in 21 days.	Rise, assuming unfertilized soil as 100.	Rise of water in 42 days.	Rise, assuming unfertilized soil as 100.	Rise of water in 42 days.	Rise, assuming unfertilized soil as 100.
Unfertilized	55.5	100.0	60.2	100.0	46.2	100.0
Potassium sulphate	62.8	113.1	68.0	112.9	55.5	120.0
Superphosphate	50.8	91.5	70.2	116.6	48.5	104.9
Nitrate of soda	39.8	71.7	55.5	92.1	39.2	84.9
Lime	31.0	55.9	32.0	53.1	32.0	69.2

Soil temperatures (*Colorado Sta. Rpt. 1902*, pp. 200-204, 214-217).—This is a tabulated record, prepared by R. E. Trimble, of weekly observations on soil temperatures at different depths in irrigated and unirrigated soil.

Investigation of Illinois soils, C. G. HOPKINS (*Illinois Sta. Circ. 64*, pp. 26, figs. 5).—A report of progress in the general and detailed soil surveys of Illinois carried on under State appropriations. More detailed accounts are to be published later in bulletin form.

The soil of the Bermuda Islands: Its origin and composition, A. E. VERRILL (*The Bermuda Islands. New Haven, Conn.: Author, 1903*, pp. 78-82).—In this article, which is part of a comprehensive treatise on the Bermuda Islands, published first in the Transactions of the Connecticut Academy of Arts and Sciences, volume 11, it is stated that "with the exception of the black peat or muck of the swamps and marshes, all of the soil of the islands has been produced as an insoluble residue, or impurity, left after the solution of the limestones and shell-sands of the islands by rain water, but it is usually mixed with more or less disintegrated limestone, and some organic matter. . . . Where the decomposition has been complete, this soil is a reddish clay, the color being due to an excess of iron oxid, but in most places the clay soil is mixed with considerable shell-sand, or grains of undecomposed rock. In many places the latter forms the greater part of the bulk." The latter are the so-called white soils composed largely of calcium carbonate. The historical record of crop production in the islands as well as the analyses reported in this article show the soils to be as a rule naturally very fertile. They have, however, been reduced by years of exhaustive culture. According to the analyses reported the red soils, which are the more important, contain lime, 3.6 to 10 per cent; potash, 0.11 to 0.17 per cent; and phosphoric acid, 0.68 to 0.74 per cent.

On the nature of the nitrogen compounds found at different depths in the soil, G. ANDRÉ (*Compt. Rend. Acad. Sci. Paris, 135 (1902), No. 26, pp. 1353-1355*).—The total and ammoniacal nitrogen obtained by boiling (for 15 hours) samples of soil taken in April and October from the surface and from depths of 30 and 60 to 65 cm. in dilute hydrochloric acid (36 per cent) and potash solution (containing 20 times as much potash as there was nitrogen in the sample of soil) are reported. In case of the treatment with potash the ammonia was removed by means of a current of hydrogen and collected in dilute acid. The results indicate that the insoluble nitrogenous compounds of the surface soil are largely transformed into soluble compounds during the summer and are widely diffused through the deeper layers of the soil during the winter, so that in the spring the lower layers of the soil contain more soluble nitrogen than the surface soil. At the end of summer, however, the distribution is quite uniform in the different layers.

The analysis of reh, the alkaline salts in Indian usar land, E. G. HILL (*Proc. Chem. Soc. [London], 19 (1903), No. 262, pp. 58-61; abs. in Chem. Centbl., 1903, I, No. 17, p. 987*).—The upland usar or alkali lands of India, covering an area of about 2,000,000 acres, mainly between the Jamna and Ganges and also between the Ganges and Gogra, are described, and the attempts to utilize them are referred to. Analyses of 5 samples of the soluble salts or reh are reported and their possible utilization on a large scale is discussed. None of the samples examined contained less than 88 per cent of sodium carbonate.

Investigations on the influence of the volume of soil on the yield and composition of plants, O. LEMMERMANN (*Jour. Landw., 51 (1903), No. 1, pp. 1-40*).—The yield and composition of mustard grown on mixtures of sand and ordinary soil under different systems of manuring in series of pots containing 30, 22½, and 15 kg. of soil are reported and discussed. The results show that both the yield and composition were affected by the size of the pot, the fertilizer apparently being more thoroughly utilized and the yield being larger in the larger pots.

Nitrification in different soils, W. A. WITHERS and G. S. FRAPS (*North Carolina*

Sta. Rpt. 1902, pp. 31-41).—In continuation of previous work (E. S. R., 13, p. 122), a study was made of the rate of nitrification of ammonium sulphate and cotton-seed meal in 8 soils of known history from different parts of the United States. The results show that "calcium carbonate exerts a decided accelerating influence upon the nitrification of cotton-seed meal and ammonium sulphate, especially the latter. In some soils a greater per cent of nitrogen is nitrified in the form of ammonium sulphate than in cotton-seed meal; in other soils the contrary is the case, even in the presence of calcium carbonate. Other soils exhibited little nitrifying power, under the conditions of the experiments."

FERTILIZERS.

Manures in use in Egypt, G. P. FODDEN (*Jour. Khediv. Agr. Soc. and School Agr.*, 5 (1903), No. 1, pp. 1-34).—Attention is called to the increasing need for fertilizers in Egypt and the limited supply at hand. In addition to Nile mud, the principal fertilizers available are sebach beladi (barnyard manure), sebach coufri ("the remains of ancient villages mixed with debris of various kinds and organic matter"), tafla or marog (a blue nitrate-bearing clay or marl), pigeon manure, and minor products, such as those derived from sewage, refuse from slaughterhouses, tanneries, street sweepings, etc. The value and use of these manures, as well as of commercial fertilizers, are discussed. Nile water contains on an average in August 170 parts of suspended matter per 100,000, 130 of which is deposited on the soil. This deposit contains on an average 0.1 per cent nitrogen, 0.2 per cent phosphoric acid, 0.6 per cent potash. The sebach coufri generally contains less than 0.3 per cent of nitrogen, 0.5 per cent of phosphoric acid, and 1 to 3 per cent of potash. The tafla or marog is very variable in composition, the content of nitrate of soda varying from 1 to 24 per cent. The average barnyard manure of Egypt contains nitrogen 0.3 per cent, phosphoric acid 0.2 per cent, potash 1.5 per cent.

The results of preservation experiments with barnyard manure stored in heaps, BACHMANN (*Deut. Landw. Presse*, 30 (1903), Nos. 36, pp. 311, 312; 37, pp. 323, 324).—Heaps of 1,200 to 1,800 kg. were experimented with. In different cases the heaps were (1) loosely made, (2) closely packed, and (3) closely packed and treated with superphosphate ($1\frac{1}{2}$ per cent), phosphoric acid ($1\frac{1}{2}$ to 2 per cent), sulphuric acid, marl, ground calcium carbonate (5 per cent), and lime (5 per cent). After standing 4 months manure was removed from each of the heaps for comparative experiments on potatoes and beets. The changes in composition (water, total nitrogen, and ash) after 4 and 8½ months are reported. The loss of nitrogen was rapid for 3 months in the loose heap and then ceased. The loss in closely packed heaps covered with earth was as large as in the loosely made heaps. The superphosphate, phosphoric acid, and sulphuric acid reduced the loss of nitrogen, sulphuric acid apparently being most effective in this respect. Marl, calcium carbonate, and lime increased the loss of nitrogen. The manure treated with superphosphate gave the highest yields, followed in order by that treated with lime, phosphoric acid, calcium carbonate, marl, and sulphuric acid. The results in general show that the larger proportion of the loss of nitrogen occurs in the early stages.

Valuation of unexhausted manures obtained by the consumption of foods by stock, J. A. VOELCKER and A. D. HALL (*Jour. Roy. Agr. Soc. England*, 63 (1902), pp. 76-114, figs. 3).—A revision of Lawes and Gilbert's tables using current values of nitrogen, phosphoric acid, and potash in common fertilizers; paying for $\frac{1}{2}$ of the nitrogen, $\frac{3}{4}$ of the phosphoric acid, and all of the potash in the purchased foods; and reducing the period over which the manure is supposed to produce an effect from 8 to 4 years, the compensation value for the second, third, and fourth years being one-half of that of the year immediately preceding.

The wide variation in the effect of green manures plowed under at different times, CAUSEMANN (*Deut. Landw. Presse*, 30 (1903), No. 31, pp. 263, 264).—The yield of the following crop of rye on light sandy soil was in every case larger when lupines were turned under September 28 than when turned under July 31.

Phosphorus versus lime in plant ash, P. Q. KEEGAN (*Nature* [London], 66 (1902), No. 1722, p. 655).—Analyses of the ash of the leaves of a number of plants are reported in support of the view that a certain proportion of lime in the soil (say 3 or 4 per cent) interferes with the assimilation of phosphorus and is so inimical to the life of certain so-called calcifugous plants which require a definite amount of phosphorus for the healthy performance of their physiological functions.

An unusual result of fertilizing on a sandy moor soil, CLAUSEN (*Jour. Landw.*, 51 (1903), No. 1, pp. 77-80, fig. 1).—Pot experiments are reported in which the yield of grain of oats was much larger and of straw smaller in case of fertilizer containing no phosphoric acid than in one containing that element. The experiments are to be repeated.

Results of experiments with potash fertilizers on moor meadows, BACHMANN (*Fühling's Landw. Ztg.*, 52 (1903), No. 7, pp. 251, 252).—A comparison of kainit and 40 per cent potash salt in which the results favored the latter, both as fall application and as spring application. Applications of lime were apparently more beneficial in case of the kainit than in case of the other salt.

On potash and on alkaline phosphatic nitrogenous bone fertilizer, J. B. SOBRINHO (*Bol. Agr. São Paulo*, 3. ser., 1902, No. 12, pp. 801-806).—This article discusses the sources of potash and describes the method devised by Ilienkov and Engelhardt of the agricultural-chemical institute of St. Petersburg for preparing bone fertilizer by treatment with caustic potash.

The manufacture of animal fertilizers (*L'Engrais*, 18 (1903), No. 15, pp. 353-355).—The preparation of fertilizers from by-products of tallow refining, from poudrette, dried meat and blood, and ground bone is discussed.

Commercial fertilizers, H. A. HUSTON and W. J. JONES, Jr. (*Purdue Univ. Spec. Bul.*, Mar., 1903, pp. 40).—"This bulletin contains the detailed report and summary of fertilizer inspections made in 1902, the full text of the Indiana fertilizer law, a list of manufacturers who have registered raw materials (nitrogen and potash compounds), and a list of all fertilizers registered that were on sale April 1, 1903." Analyses of 679 samples are reported.

Analyses of commercial fertilizers, W. C. STUBBS (*Louisiana Stat. Bul.* 73, 2. ser., pp. 1-173, 177-189).—This bulletin gives the text of the State fertilizer law; statistics of the fertilizer trade in Louisiana; brief notes on the sources of fertilizing materials, the purchase and valuation of fertilizers; and tabulated analyses of several thousand samples of fertilizing materials, including mixed fertilizers, acid phosphates, cotton-seed meal, bone, tankage, dried blood, nitrate of soda, sulphate of ammonia, muriate of potash, sulphate of potash, kainit, bat guano, slag, floats, and boneblack.

Inspection of fertilizers in 1902 and analyses of wood ashes and miscellaneous fertilizing materials, F. W. MORSE ET AL. (*New Hampshire Sta. Bul.* 97, pp. 12).—Analyses of 81 brands of fertilizers inspected in cooperation with the State board of agriculture and 9 samples of ashes, 2 of superphosphate, 1 each of South Carolina floats, ground bone, tankage, cotton waste, nitrate of soda, and sulphate of potash, 2 of insecticides, and 5 of muck, are reported. The text of the fertilizer law which went into effect in 1901 is given.

Some facts about commercial fertilizers in New York State, L. L. VAN SLYKE (*New York State Sta. Bul.* 230, pp. 18).—This bulletin discusses the importance of the fertilizer trade in the State and points out "how better economy may be realized in purchasing plant foods." The recommendations include (1) the purchase of high-grade fertilizers, and (2) the purchase of unmixed materials. The more economical

sources of phosphoric acid, potash, and nitrogen are pointed out, and illustrations are given of 3 types of plant food mixtures.

Fertilizer analyses, fall season, 1902, B. W. KILGORE (*Bul. North Carolina State Bd. Agr.*, 24 (1903), No. 2, pp. 43-56).—Analyses and valuations of 194 samples of fertilizers are reported.

Fertilizer analyses, spring season, 1903, B. W. KILGORE (*Bul. North Carolina State Bd. Agr.*, 24 (1903), No. 3, p. 31).—This bulletin reports analyses and valuations of 59 samples of fertilizers.

Analyses of commercial fertilizers, J. L. HILLS and C. H. JONES (*Vermont Sta. Bul.* 98, pp. 27-48).—This bulletin gives the main provisions of the fertilizer law as amended by the general assembly of 1902, discusses the valuation of fertilizers, and reports analyses and valuations of 39 samples of fertilizers. A table showing the average composition of different brands examined during the past 5 years is given.

A consideration of water in its relation to the fertilization of the soil, with some analytical studies of the mud of the River Piave, R. ONOR (*Staz. Sper. Agr. Ital.*, 36 (1903), No. 2, pp. 107-132).

FIELD CROPS.

Report of the agriculturist, A. H. DANIELSON (*Colorado Sta. Rpt.* 1902, pp. 131-136).—Brief outlines of the different kinds of experimental work with field crops conducted at the station are given. In cooperation with this Department experiments are conducted with sugar beets, grasses and forage plants, and grains, including winter wheats. The other experiments comprise culture and variety tests with wheat, spelt, emmer, einkorn, alfalfa, brome grass, and field beets. Fertilizer tests with nitrate of soda for wheat and oats are also in progress.

Forage crops, grasses, alfalfa, clovers, etc., W. R. DODSON (*Louisiana Stas. Bul.* 72, 2. ser., pp. 95, pls. 8).—Notes are given on the present status and methods of cultivation of a large number of forage plants, including alfalfa, cowpea, Spanish peanuts, lespedeza, red clover, crimson clover, white clover, soy bean, burr clover, velvet bean, hairy vetch, beggar weed, various varieties of sorghum, oats, winter barley, rye, Bermuda grass, carpet grass, large paspalum, crab grass, Italian rye grass, teosinte, redtop, smut grass, Johnson grass, barnyard grass, switch cane, rescue grass, meadow barley, corn stover, dwarf Essex rape, and cassava. The cultivation of alfalfa is gradually becoming more extensive in Louisiana, especially along the Red River bottoms where very favorable conditions are found. The bulletin contains a copy of a paper on alfalfa read before a farmers' institute by W. L. Foster. Experiments with velvet bean showed that both as a forage and a fertilizer crop this plant is fully equal if not superior to cowpea.

Experiments with phosphatic fertilizers in 1900-1901, O. REITMAIR (*Ztschr. Landw. Versuchs. Oesterr.*, 6 (1903), No. 2, pp. 95-194, map 1a).—The results of extensive cooperative tests with phosphates conducted throughout Austria are given in tables. The method of conducting these tests is described, the use and value of phosphoric acid is discussed, and the general effect of this element in different forms is pointed out. The normal application consisted of 60 kg. of phosphoric acid per hectare. In all tests sulphate of ammonia furnishing 26 kg. of nitrogen and 40 per cent potash salt furnishing 42 kg. of potash per hectare were used.

Winter rye was much more responsive to phosphates than winter wheat. Of the different forms for wheat and rye superphosphate was the most effective. Comparing the results obtained with rye Thomas slag ranked very close to superphosphates in effectiveness and proved even more profitable. These 2 forms were closely followed by Algerian and Belgian phosphates. Of the phosphoric acid furnished in

superphosphate 8.2 per cent was utilized by the crops, and of the quantity given in the other 3 forms 7 per cent was used. Doubling the application of Algerian phosphate gave but a slight increase in yield and was not profitable. The effect of the crude phosphates on rye was quite marked but on wheat it was very slight. From the results with rye the author concludes that 60 kg. of phosphoric acid per hectare is beyond the optimum for all the phosphates used. Winter rye utilized on an average 20 kg. of phosphoric acid per hectare. The quantities taken up by the crop on different plats varied considerably. Owing to this variation in the results with rye and to the limited number of tests with wheat no definite applications are recommended.

The progress of absorption of nitrogen by cereals, J. HENRY (*Bul. Agr. [Brussels], 19 (1903), No. 1, pp. 154-156*).—A record is given of the growth, weight, and nitrogen content of barley, wheat, and rye at different periods, which shows that the absorption of nitrogen varies widely at different stages. Two periods of maximum absorption were observed in case of wheat, viz, from May 7 to 17 and at the time of the formation of the grain. Similarly for rye the periods of greatest absorption were April 19 to 29 and June 11 to 26 (the time of formation of grain). In case of barley the maximum absorption was at time of heading, June 12 to 26.

Review of agricultural experiments, A. P. AITKEN (*Trans. Highland and Agr. Soc. Scotland, 5. ser., 15 (1903), pp. 94-134*).—This is a review of experiments in agriculture which are being carried on by various institutions in Great Britain, with a view to showing the amount and source of this work, the direction it is taking, and the progress which is being made. Special attention is called to the lack of knowledge regarding the soils of the country, and the way in which this affects the experimental work and its interpretation.

Corn experiments in Illinois (*Illinois Sta. Circ. 66, pp. 14*).—This is a report of progress on the different lines of investigation with corn which have been carried on under State appropriations at the station.

The acidity of corn silage, F. W. MORSE (*New Hampshire Sta. Bul. 96, pp. 115-117*).—Analyses are given of several samples of corn silage made from different varieties of corn and analyzed at different times during the years 1895 to 1899. The average total acid content of samples of Sanford corn silage varied from 1.5 per cent acetic acid in 1895 to 1.95 per cent in 1897. With Leaming corn the variations ranged from 0.67 per cent in 1896 to 1.47 per cent in 1897. The average of 5 samples of Mosby Prolific, taken between March 17 to 31, 1896, was 0.82 per cent. Analyses in 1899 of silage made from Leaming corn showed that the acidity of the surface silage was usually lower than that of the silage 6 or 8 in. below the surface, the average results being 0.83 per cent for surface silage and 1.03 per cent acetic acid for silage not less than 6 in. below the surface.

Cotton culture, R. J. REDDING (*Georgia Sta. Bul. 59, pp. 221-250*).—Experiments similar to those conducted in previous years are reported (*E. S. R., 13, p. 1038*). In 1902, 26 varieties were under test. Moss Improved, Peterkin Improved, Schley, Allen Prolific, Texas Bur, Woodfin Nonpareil, and Prize, given in the order of their value of total products, head the list in profitable returns, their values ranging from \$31.22 to \$35.02 per acre. The first 5 varieties mentioned ranked in the same order in the production of lint cotton. Considering the general results for the last 9 years in this line of work, large bolls, large seeds, and a high percentage of lint are closely related to the greatest value of lint and seed. Brief notes on some of the varieties under test are given with directions for selecting a variety and for selecting seed in the field.

As in previous years, a mixture of an early and a late maturing variety was tested. The varieties used this season were Schley and King Improved, of which 15.5 and 10 lbs. of seed per acre, respectively, were planted. King Improved, the early variety, yielded much less than Schley and the mixture was also found unprofitable. Average

results for 5 years show that the yields per acre of medium varieties were 90 cts. greater in value than the yields of early varieties, while the yields of the mixtures exceeded those of the medium varieties by \$1.34. If the 2 varieties are equally productive from year to year it is considered expedient to mix them.

The results of distance experiments conducted for 4 years are in favor of spacing plants 12 in. apart in 4-ft. rows. This test had reference only to the distance between plants in the row. From a series of experiments the author concludes that on upland middle Georgia soils, capable of yielding 800 to 1,200 lbs. of seed cotton per acre, the rows should not be wider than 36 in. and the plants in the row not over 12 in. apart.

An unfavorable season and the appearance of rust interfered with the results of a fertilizer test made for the purpose of determining the best proportion of nitrogen in a mixture containing available phosphoric acid and potash in the constant proportion of 4:1. As the nitrogen was diminished in the applications the phosphoric acid and potash were increased to the extent of making the money value of the application uniform in all cases. The general application of nitrogen was given in the form of cotton-seed meal, but in each case 15.6 lbs. of nitrate of soda were applied when the seed was planted. The experiment was made in duplicate. Where cowpea vines had been turned under before planting to cotton the crop practically escaped injury from rust. In a general way, the results of one experiment indicated that the yield increased quite regularly as the supply of nitrogen was diminished. In the duplicate test lack of moisture interfered with the results.

In the second fertilizer experiment potash in the form of muriate was successively diminished and the quantity of acid phosphate and cotton-seed meal correspondingly increased so that in all cases the cost of the fertilizer amounted to \$4.17 per acre. In this test the fertilizers were practically without effect.

The weather conditions during the growing season for a series of years are tabulated. Fertilizer formulas for various crops on different kinds of soils are given in an appendix.

Cotton culture, J. S. NEWMAN (*South Carolina Sta. Bul.* 75, pp. 13, figs. 3).—Popular directions are given for the culture of cotton in South Carolina.

Peas and the pea weevil, C. A. ZAVITZ and W. LOCHHEAD (*Ontario Agr. Col. and Expt. Farm Bul.* 126, pp. 32, figs. 9).—This bulletin contains a summarized account of the cultural work with peas at the Ontario Agricultural College, together with the results of experiments in the control of the pea weevil. The pea weevil is described in detail and a map given showing the present distribution of this insect in Canada. More than 100 varieties of peas have been grown in the experimental grounds at the college during the past 14 years. A table is given showing the character of the vines as regards growth and susceptibility to weevils, yield, etc., of 26 leading varieties for a period of 7 years.

Some varieties of peas, like New Canadian Beauty, are double in size those of other varieties like Common Golden Vine, and hence in seeding it has been found necessary to vary the amount sown from 2 to 3½ bu. per acre. The time of maturity has varied for 26 varieties from 94 to 101 days and the extremes in length of vines from 19 to 52 in. The yields per acre have varied from 23 to 38 bu. The average weight per bushel has been 59.4 lbs. for whole peas. Weevilled peas varied in weight from 38 to 52 lbs., and usually the smaller the peas the greater amount of injury done by weevils. The best yielding varieties for the whole province, averaging upward of 25 bu. per acre, are the Egyptian Mummy, Chancellor, Prussian Blue, and Striped Wisconsin Blue. Other varieties averaging between 24 and 25 bu. per acre are Early Britain, Canadian Beauty, and Canada Cluster. The reports of experimenters show that with but few exceptions there are no pea weevils north and east of a line drawn from Brockville to Midland.

Experiments for a number of years in selecting large and small seed of the same variety resulted in an average yield of 30.3 bu. of grain and 1½ tons of straw per acre

for large seed as against 23.9 bu. of grain and 1.1 tons of straw per acre for small seed. Using the split pea seed as it came from the thrasher in comparison with whole seed, the average yields were 10 bu. of grain for the former and 30.7 bu. for the latter. Only about 30 per cent of weevilly peas were found to germinate. In seeding peas at different dates between April 18 and May 23, the average yield for the former date was 21 bu. per acre and for the latter 9 bu. per acre. There has been an average increased yield in 30 experiments of 1.3 bu. per acre from seeding peas in drills rather than broadcasting.

Peas were grown in combination with a number of different crops for both forage and grain. The average results of 6 years' experiments with 11 different mixtures indicated peas and oats in the proportion of 2 bu. of oats to 1 bu. of peas as the best mixture. The best results as to fodder were obtained when the Siberian oats and Prussian Blue peas constituted the mixture. In cooperative experiments with farmers throughout Ontario for a period of 5 years, a mixture of tares and oats has exceeded in yield a mixture of peas and oats by about 600 lbs. of green fodder per acre, and it is therefore recommended that in those portions of the province where the pea weevil is troublesome spring tares be used instead of peas to mix with oats. Where peas and oats are grown together for green fodder in weevil-infested districts it is recommended that the crop be cut when the peas have reached the blossoming stage. As regards the yield of grain of several different mixtures, the best results were obtained from a mixture of oats and barley. Peas have been seeded with oats as a pasture crop for cattle, but without very satisfactory results, the oats being eaten much more readily than the peas. The mixture, however, is believed to be very suitable for either sheep or swine. The value of peas as a green manure for wheat is shown in the average results obtained during the period of 4 years in which wheat grown after peas averaged 36.1 bu. per acre, after rape 30.4 bu. per acre, and after buckwheat 29.6 bu. per acre.

Grass peas have proved perfectly resistant to the weevil in Ontario and have yielded at the rate of about 25.7 bu. of grain and 2.2 tons of straw per acre. One year the yield was slightly over 43 bu. per acre. From the average results of 27 cooperative experiments conducted throughout Ontario in 1901, the Grass pea yielded about $\frac{3}{4}$ bu. per acre less than the Early Britain variety and $\frac{1}{2}$ bu. more than White Wonder variety. The yield of forage has been about the same as that obtained from common tares. The Egyptian or chick-pea (*Cicer arctinum*) has been grown at the station, yielding at the rate of about 35.6 bu. of grain and 1 ton of straw per acre. This grain is slow in reaching maturity and the straw is of poor quality.

Directions are given for destroying the pea weevil by the use of carbon bisulphid, and it is recommended that the growing of both field and garden peas be discontinued for at least 2 years in those districts where the weevil is now abundant, and that such crops as Early Yellow soy beans, Grass peas, emmer, mixed grains, etc., be substituted.

Experiments with oats, Aberdeen, 1901-2, J. WILSON and W. M. FINDLAY (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 15 (1903), pp. 183-196, figs. 9).

Sisal, the Yucatan fiber, E. H. THOMPSON (*Amer. Inventor*, 10 (1903), No. 12, pp. 239-241, figs. 13).—An account of the culture and the manufacture of fiber from sisal.

Sugar-beet investigations in Illinois, C. G. HOPKINS and L. H. SMITH (*Illinois Sta. Circ.* 62, pp. 6).—This is a brief report of progress on cooperative experiments with farmers throughout the State and on investigations at the station.

Macaroni wheat in South Dakota, E. C. CHILCOTT (*South Dakota Sta. Bul.* 77, pp. 3-28, pl. 1, figs. 2).—In addition to reporting experimental results this bulletin describes macaroni wheat and discusses its adaptability to South Dakota and its present and prospective market.

A list of farmers who entered into a cooperative culture and variety test with macaroni wheat is given, together with extracts from reports on the results obtained

by the different parties. At the station in 1901, 12 varieties of macaroni wheat yielded on an average at the rate of 21 bu. 26 lbs. per acre as compared with 10 bu. 33 lbs. for 9 varieties of bread wheats. In 1902 the results in yield were also largely in favor of the macaroni wheats, but the conditions this season did not warrant definite conclusions; the bread wheats being later than macaroni wheats were more subject to rust attacks. In several cases the same variety of macaroni wheat gave widely different results on different plats.

The general conclusions drawn from the results are that macaroni wheats are adapted to South Dakota, produce greater yields than Blue Stem and Fife wheats, and are more drought resistant than bread wheats. The following varieties have given good results: Pellissier, Berdiansk, Kubanka, Arnautka, Gharnovka, Yellow Gharnovka, Taganrog, Argentine, Medeah, Velvet Don, and Black Don.

Wheat and milling, A. GIRARD and L. LINDET (*Le froment et sa mouture*. Paris: Gauthier-Villars, 1903, pp. VII + 355, pls. 6, figs. 82, dgm. 3).—A comprehensive work treating of the composition, storage, and milling of wheat, as well as the nutritive value of wheat and its milling products and related topics.

HORTICULTURE.

A selected list of vegetables for the garden, F. W. RANE (*New Hampshire Sta. Bul.* 99, pp. 25-43, figs. 18).—As a result of experimentation the author has compiled a list of vegetables for culture in New Hampshire. This list is as follows:

Green-Pod Bush Beans.—Giant Stringless Green-Pod Valentine, Stringless Green-Pod, Early Six Weeks, Dwarf Horticultural. *Bush Wax Beans*.—Wardwell Kidney Wax, Currie Rust-Proof Wax, Market Wax. *Lima Beans*. Bush Lima Beans. *Beets*.—Eclipse, Crosby Egyptian, Arlington Favorite. *Cabbage*.—Early Spring, Winingstadt, Early Summer, Succession, Lupton. *Carrots*.—Danvers Half-Long, Chantenay. *Cauliflower*.—Snowball, Erfurt. *Celery*.—Golden Self-Blanching, Boston Market, Pascal. *Sweet Corn*.—Early Cory, Crosby Early, Potter Excelsior or Squantum. *Cucumbers*.—White Spine. *Eggplant*.—New York Improved Large Purple. *Lettuce*.—Big Boston, New York or Wonderful, Grand Rapids, Crumpled Leaf. *Muskmelon*.—Emerald Gem, Rockyford or Nettle Gem, Montreal, Long Yellow. *Watermelon*.—Cole Early, Boss, Black-Eyed Susan. *Onion*.—Yellow Danvers. *Parsnip*.—Hollow Crown. *Early Peas*.—Gradus or Prosperity, Claudit, Nott Excelsior. *Late Peas*.—Telephone, Stratagem. *Peppers*.—Sweet Mountain, Large Bell or Bull Nose, Improved Thick Long Red. *Potatoes*.—Early Rose, Delaware, Green Mountain, Washington. *Pumpkin*.—Small Sugar, Golden Oblong. *Radish*.—Early Scarlet Globe, French Breakfast, Wood Early Frame. *Squash*.—Early Prolific Marrow, Essex Hybrid, Warren, Hubbard. *Tomatoes*.—Earliana, Dwarf Champion, Stone, Beauty. *Turnip*.—Early Milan, Early Snowball, White Egg, Red Top Globe. *Sweedes or Ruta-Baga*.—American Purple Top Ruta-Baga.

Cultivation of vegetables, and notes on varieties, G. COOTE (*Oregon Sta. Bul.* 74, pp. 20).—Popular directions are given for the culture of onions, peas, string beans, Lima beans, horse or broad beans, vegetable marrows, cauliflower, and broccoli. Notes on the behavior of varieties of these vegetables when grown at the station are included. Lima-bean seed grown at the station gave stronger and more productive plants than seed of the same variety obtained from an Eastern seed firm.

Report of the horticultural division, W. F. MASSEY (*North Carolina Sta. Rpt.* 1902, pp. 18-28).—This is a brief review of experiments with grapes, tomatoes, lettuce, roses, potatoes, sweet corn, bulbs, and cantaloupes.

Cucumbers under glass, G. E. STONE (*Massachusetts Sta. Bul.* 87, pp. 3-29, 42, 43, figs. 9).—A discussion of the botany of the cucumber seed, types of cucumber houses with estimates as to their relative economy, importance of light in cucumber culture,

and the details of forcing, including varieties, temperature, watering, transplanting, pruning, pollination of flowers, etc. Relative to houses the author says: "The cheapest and most economical house to build and operate in the production of cucumbers is an even or two-thirds span house of large dimensions, such as is most frequently used by lettuce growers. The construction, heating, and management of a large house are proportionally cheaper than of a small house."

The variety of cucumber chiefly grown is the White Spine or some similar sort, though in many instances a cross between White Spine and the English forcing variety Telegraph is used. Giant Pera sometimes crossed with White Spine does not produce a desirable hybrid. A night temperature of 65° and a day temperature of 85° F. is considered the most desirable, and a higher temperature in sunshiny weather. Transplanted plants have not been found to grow faster or make better plants than plants grown directly in the seed bed. The results secured in experimenting on the effects of various amounts of light show a difference of 10 to 80 per cent in the maturity of cucumber plants caused by exposure to single, double, and triple layers of glass. These experiments and others in which the activity of starch development in the leaves of the plants on sunny days was observed, using first and second quality glass, clean and unclean glass, etc., brought out clearly the much greater carbon dioxid assimilation of the plants with every increase in the amount of light. Shadows caused by heavy frames or adjacent buildings retarded assimilation and gave rise to immature plants. With plants in the greenhouse 24 to 30 in. apart the author believes the 1-shoot system of training preferable to training 2 shoots.

In pruning experiments with White Spine, in which a single leader and several laterals were allowed to grow without pruning, "the average yield of fruit on the main shoot was 18 per cent higher than upon the laterals. The lowest laterals, or those nearest the base of the plant, came next in the production of fruit, and the others or higher laterals followed in uniform succession in fruit production. The fruit matured earlier upon the main shoot than upon the laterals, the lowest laterals more nearly approaching the main shoot in this respect, and the other laterals following in uniform succession. The main shoot showed a gain of 36 per cent in the length of time required to mature its fruit over the first lateral. Of the fruit formed on the laterals, 61 per cent occurred in first axils. The number of internodes between the successive formation of fruit on the plant was in the largest number of cases seven."

Considerable other data along this same line are given with 4 varieties in which the plants were allowed to develop a single leader and as many laterals as appeared, the laterals being pruned at the second leaf, or in case fruit did not set in the first axil of the lateral they were pruned just beyond the axil where it did set. In the latter experiments 93 per cent more pistillate flowers were found on the laterals than on the leader.

"Cutting the leader of the main shoot or pruning the laterals caused an increase in the number of laterals. Where laterals are not cut, they are not formed as a rule in the axil of every leaf. Pruning causes a larger amount of fruit to set in the first axils of the laterals, as it was found that in the experiment where pruning was practiced 91 per cent of the axils produced fruit, against 55 per cent where no pruning took place. In some instances where the leader was nipped on unpruned plants, this resulted in causing a slight increase in the amount of fruit in the first axil of the laterals. In conclusion it may be stated that from our experience the advantages of pruning seem to be an increase in the yield of fruit, and a concentration of fruit on the plant."

Notes are given on the lack of color in cucumbers, productiveness, and the vitality of cucumber seeds.

The origin of various varieties of American muskmelons, F. W. RANE (*New*

Hampshire Sta. Bul. 96, pp. 125-133).—The author has made a study of the origin and history of all of the well-known varieties of American muskmelons. A table showing the origin, introducer, and year of introduction of 54 varieties is given in the bulletin, together with a number of letters from various seed firms giving data and notes along the same lines. It was believed when the experiment was undertaken that a large number of American muskmelons would be found to be of definite origin. This belief was not substantiated. Very few varieties of known parentage were found. For the most part the varieties are chance seedlings or strains of well-known kinds.

From the notes obtained from seed firms it appears that the Green-fleshed Osage muskmelon came from a variety called Grand View, which in turn was an impure strain of Emerald Gem. Long Island Beauty is a variety of the Hackensack type originated on Long Island. Miller Cream was originated by John D. Miller, of Elmira, N. Y., in 1878, and is believed to have been a cross between Sill Hybrid and Cassava. Osage is believed to be an improved selection from Miller Cream. Osage Gem was a cross between Osage and Netted Gem. Paul Rose is a selected form of Osage. The winter muskmelons Eden, Khiya, and N. E. Hansen have been brought to prominence chiefly through the influence of J. F. Brown, of Utah. Ideal was originated by Professor Price of the Texas Agricultural College and Station.

Onion growing in the Cache la Poudre Valley, W. PADDOCK (*Colorado Sta. Bul.* 81, pp. 10, figs. 3).—A popular discussion of the onion-growing industry in the Cache la Poudre Valley, dealing with soils, preparation of land, fertilizing, seeding, cultivation, irrigation, harvesting, markets, varieties, etc. Yellow Globe Danvers is practically the only variety grown. Sowing the seed in the seed bed and transplanting to the open field has not been found profitable in that section. The cost of growing the crop is estimated to be from \$50 to \$90 per acre, averaging probably about \$60 per acre. The prices received vary from 65 to 75 cts. per 100 lbs. in the fall.

The tomato industry of the Arkansas Valley, H. H. GRIFFIN (*Colorado Sta. Bul.* 78, pp. 20).—This bulletin records the results of 3 years' experiments and observations with tomatoes in the Arkansas Valley, and gives suggestions on the culture of tomatoes, including irrigation, the control of pests, diseases, etc. At present 5 canning factories are located in the valley. These are not always fully supplied with tomatoes. Factors tending to lower yields in the valley are strong winds, aridity, dashing rains, and too late planting or planting on impoverished soil. As the result of experiments in 1900 it was decided that pruning the plants in field culture was not advisable. Plants started in the hotbed and transplanted to the field produced fruit earlier and gave a greater total yield than plants grown from seed sown in the field. The variety Perfection ripened fruit about 3 weeks earlier than Stone, and yielded heavier. Hail interfered with the station experiments of 1901. Observations in the neighborhood that year showed that the heaviest yields were obtained from plants set early in May rather than later. On one farm the crop on land manured with 9 loads of sheep manure per acre ripened fruit about 3 weeks earlier than where no manure was used. Strong, stocky plants grown at the station produced larger and earlier crops than plants that had not been transplanted before setting in the field, or plants grown from seed sown in the field. The author found that it required about 40 to 45 days after setting for the fruit to ripen.

The best results in tomato growing were found on virgin sandy soils. Much adobe is not desirable. Transplanting tomato plants is of no advantage unless done early enough to permit of an increase of the root system. A good stocky plant should be 6 to 8 in. high and about as thick as a lead pencil when set in the field. On well fertilized land plants should be set 4 ft. apart each way. In irrigation the greatest quantity of water should be applied when the fruit is growing. Too much water early in the growth of the crop produces a tender growth of yellowish color. Irrigation late in the season after the nights have become cold may retard ripening.

In a test of 17 varieties of tomatoes Beauty was the most satisfactory for canning purposes. It is an early variety, of good appearance and quality, and one of the most productive varieties grown. It also stands shipping well. Acme is a somewhat earlier variety and may be preferred for early shipment. Fordhook First is also considered a good early variety.

Fertilizers for market-garden crops, B. DYER (*Jour. Biol. Agr. [London]*, 9 (1903), No. 4, pp. 461-481).—This work has been noted from another source (*E. S. R.*, 14, p. 981).

Experiments in orchard culture, R. A. EMERSON (*Nebraska Sta. Bul.* 79, pp. 33, figs. 12).—This bulletin reports the results of (1) tests of various methods of orchard culture to determine the effects of each method on soil moisture and the growth of young orchard trees, (2) tests of cover crops to determine their effects on fall development and winter injury of young peach trees, and (3) tests of soil covers and of various amounts of soil moisture on the root killing of apple and cherry stocks.

In the first instance a young orchard set in the spring of 1901 was divided into 8 plats, each plat containing 30 apple, 12 cherry, 10 peach, 10 pear, and 14 plum trees. One plat was cropped with watermelons and kept cultivated throughout the season, another with pole beans, and one with corn. One plat was given clean cultivation throughout the two seasons of 1901 and 1902. Another was cropped with oats both seasons. Three plats were given clean cultivation during the early part of both seasons and then seeded, one to millet, one to oats, and weeds allowed to grow on the third. In addition to the above plats, a ninth smaller plat on which no trees were grown was seeded to rye to note the effect on soil moisture. During the season for the 4 months from May to August, inclusive, only a little over 7 in. of rain fell in 1901, while during the same period in 1902 28 in. fell.

In these experiments rye, during the first season, dried the ground most of all the different methods of cultivation. This plat became dry earlier and remained dry nearly a month longer than any other plat. Next to rye the oat crop dried the ground most seriously, though not to a much greater degree than did corn and cover crops. The oat plat became dry, however, about 2 weeks earlier in the season and the drought lasted much longer than on the corn plat. The soil in the cover-crop plats did not become dry for a week or two after the corn ground did. Clean cultivation dried the soil the least of any of the different methods of culture, while vegetables dried the soil but little more than clean cultivation. There was from two to three times as much moisture available to plants during the dry season in the clean cultivated plat as in the oat plat. Both the oat and cover-crop plats absorbed more moisture during heavy rains than the clean cultivated plat, but this was counterbalanced by the more rapid loss during periods of dry weather.

The effect of drought on the young orchard was especially noticeable on the oat plat, where more than 50 per cent of the trees died. On the other plats the loss varied from 2 trees on the clean cultivated plat to 5 where vegetables were grown, 7 on the corn plat, and 9 where cover crops were used, out of a total in each case of 76 trees set. Tables are given showing the average height and breadth of the top and diameter of the trunks of trees on the different plats.

In summarizing the results of these tables the author states that all things considered—drought killing, height of tree, breadth of top, and diameter of trunk—"the vegetable and clean cultivation plats rank first, the former being slightly ahead of the latter. The next in rank are the cover crop and corn plats, the former being very slightly ahead of the latter. The oats plat naturally ranks lowest, much lower than the corn and cover crop plats."

The serious drying effect of rye is noted in one other case where rye was seeded in a bearing orchard. During the summer of the drought only a few trees died, but the following season the spring was very dry, and although abundant rains came in

June all the trees in this orchard died of drought during one of the wettest seasons on record in Nebraska.

In the study of the effect of cover crops on fall development and winter injury of young peach trees, 2 orchards of 48 trees each were set, one orchard on bottom land and the other on upland. Both orchards were given clean cultivation up to about the middle of July each year, then each orchard was divided and one-third seeded to oats, one-third to millet, and the remaining third given clean cultivation throughout the fall. In 1901 all the trees on the upland stopped growth early in the fall and no great difference was noticeable in the maturity of the wood of the trees in the different plats. On the bottom lands the trees on the cover crop plats stopped growing about the middle of August, but growth was continued on the cultivated plat until much later. The following spring it was found that many of the trees on the bottom lands had been badly injured, half the trees on the late cultivated plats being dead and the remainder seriously injured. On the cover-crop plats about half the trees were badly injured, while the remainder were unhurt. Not a single tree was dead. About $\frac{1}{3}$ more trees were injured where oats were seeded than where millet had been used. None of the trees on the uplands was seriously injured by the winter's cold, though on the late cultivated plat nearly all the trees showed considerable brown coloration beneath the bark. The results secured in 1902 are not yet complete. They show, however, a better ripening of the wood on the cover-crop plats than on the cultivated plats.

In the third experiment 7 boxes, each 2 ft. square and 18 in. deep, were filled with loam soil of varied water content. In each box 25 apple and 10 cherry seedlings were planted. Six of the boxes were set outdoors about the middle of December. Hay was placed between and around the boxes and covered with soil. One box of trees was stored in a cool, dry cave. Of those left outdoors one box was covered with a mulch of straw 4 in. deep, one was protected with a covering of snow about 4 in. deep whenever snow fell, and the remaining boxes were left without any covering, snow being swept off when it came. The following February, when the boxes were examined, none of the cherry roots had been injured enough to prevent their growing, and there was practically no difference in the degree of injury in the different boxes. The apple roots, however, were considerably injured, the greatest injury occurring in the drier soils.

Out of 25 apple trees set in the unprotected box containing 10.4 per cent of moisture, 20 trees were dead and 5 injured. In the unprotected box containing 15.2 per cent of moisture, 19 trees were dead and 6 injured. In the box with a moisture content of 19.8 per cent, 3 were dead, 10 injured, and 12 uninjured. In an unprotected box containing 25.6 per cent of soil moisture, 8 trees were dead, 4 injured, and 13 uninjured. The box covered with the straw mulch contained 16 per cent of soil moisture, and none of the trees were dead in this box and but 7 injured. In the box covered occasionally with snow, and containing 15.8 per cent of moisture, 7 were dead and 8 injured. Not a tree was injured in the box stored in a cool, dry cave, though it contained but 10 per cent of soil moisture. This is believed to show that the winter injury to apple roots is not alone due to dryness of the soil, but to cold and dryness combined. The mulch was advantageous in preventing the alternate freezing and thawing which took place in bare soils. A record is given showing the depth of frost in bare ground and ground covered with a millet cover crop.

In conclusion, the author states that a cover crop is one of the best means for protecting the roots of trees from winter injury. Likewise any method of culture that leaves the ground moist in fall has an advantage over methods that leave the ground dry. In the station experiments the soil under cover crops that have been killed by early frosts has been as moist on the approach of winter as soils given clean cultivation throughout the fall. For the young orchard, thorough cultivation in early summer, followed by a cover crop in the fall, is advocated.

"Good cultivation in early summer can often be given young trees by growing some cultivated crop in the orchard. Tender crops are best, since they can not be sown so early as to dry the ground seriously in spring, and are killed by fall frosts, thus preventing very late drying. Cropping with corn, for instance, insures fairly thorough early cultivation, and corn is a fair substitute for a cover crop in fall and winter."

A study of Northwestern apples, N. E. HANSEN (*South Dakota Sta. Bul. 76, pp. 143, figs. 84*).—This bulletin discusses methods of propagating apples and of originating new varieties, best varieties of orchard and small fruits for planting in the Northwest, and the terms used in describing apples; and gives descriptions of more than 300 varieties of apples, including notes on their origin. A key or system of classification is proposed by means of which the names of unknown varieties of apples may be determined. The necessity of very hardy varieties of apples for the Northwest is discussed in some detail by the author, and the standing offer of the Minnesota State Horticultural Society of \$1,000 to the originator of a variety of apple that shall be as hardy as the Duchess, equal in quality, size, and appearance to Wealthy, and possess the keeping quality of Malinda, is noted. As a stock for apples the station has found the Siberian crab (*Pyrus baccata*) perfectly hardy. The Russian Apple Nomenclature Commission, appointed in 1898 by interested societies in Minnesota, Iowa, Wisconsin, and South Dakota, of which the author was secretary, defined and described 14 groups of apples, strongly favoring Duchess, Hiberna, Chathamoff, Anisim, Yellow Sweet, Repka Malenka, Longheld, Cross, and Christmas as the best for the average planter. Since then a number of seedlings have arisen in the different States, but it will require a "test" winter such as that of 1884-85 before their hardiness can be fully determined.

In growing apples from seed the author has found that seeds obtained from cider mills should be separated from the pomace before planting, since the fermenting pomace contains an acid injurious to their germination. Clean seed washed from the pomace within 24 hours after pressing should be spread out to dry for a day or two, then mixed with moistened sand and buried in small boxes with holes in the bottom for drainage in well-drained spots in the garden over winter. The author has been most successful at the station in planting the seeds in beds 4 feet wide surrounded by boards a foot high and given half shade by means of a lath screen as soon as the seedlings appear above the ground. Fall planting 1 in. deep in rows 10 in. apart and heavily mulching over winter with coarse rotten manure is preferred. In discussing the reproduction of varieties the author quotes G. P. Peffer, originator of the Pewaukee, Peffer, and other varieties of apples, as holding that any apple will reproduce itself from seed if inbred by covering the blossoms to prevent access of pollen from other varieties.

South Dakota is divided by the author into 12 districts, and varieties of apples, plums, cherries, native fruits, raspberries, blackberries, currants, gooseberries, strawberries, and grapes are recommended for each section.

Propagation of plums, third report, F. A. WAUGH (*Vermont Sta. Rpt. 1902, pp. 249-260, figs. 5*).—The work here reported is in continuation of that of the two preceding years (*E. S. R.*, 14, p. 43). The nursery work in 1900 consisted in propagating 5 different varieties of plums, each representative of a class, on 5 different stocks. The varieties used were Stoddard, Bavay, Chabot, Milton, and Newman, and the stocks Americana, Miner, Marianna, Peach, and Sand Cherry. Each variety was grafted on each stock, thus making 25 different lots. There were 60 grafts made in each lot. One-half of the grafts in each lot were planted in Vermont and the other half in Maryland. The grafts at the Vermont Station practically failed. This result taken in connection with other work indicates that nursery stock can not be profitably produced in Vermont. All the grafts produced a satisfactory growth in Maryland except Bavay, which was wholly unsatisfactory. Data on the growth of the tops and

roots of the other varieties are recorded in detail. In general, trees on Miner roots were poor, while those on Peach and Sand Cherry were especially good. Milton and Newman showed the largest number of live trees on the different stocks and Chabot the least. The striking feature of the experiment was the excellent results obtained on Sand Cherry stock (*Prunus pumila besseyi*).

The root systems of the different stocks are illustrated and described, and the orchard characters of the trees noted. In the author's opinion too much stress has usually been laid on the value of fibrous roots in transplanting trees. Freshness and vigor should constitute the chief desiderata in the roots of the nursery tree. The root system of trees on Americana stocks was rather small, but vigorous and hardy, and the union with most plums, especially Americana varieties, was excellent. The root system of trees on Miner stocks was weak in every respect. There were no tap or fibrous roots, and the lateral branches were scattering and irregular. The best root system on the whole was found on Marianna stocks, while the union of this stock with most varieties was excellent. Fairly good root systems were produced on Peach stocks, but the union was generally poor. The Sand Cherry stocks, while used at the station for only a year, have given remarkably fine root systems. }

A summary is given of the experiments made during the past 3 years with different stocks and varieties, from which it appears that Chabot makes a comparatively slow growth and nearly always gives a lower percentage of trees than any other variety. Americana roots make good unions and give comparatively stout, stocky trees which, however, are measurably dwarfed. Marianna stocks have generally given long, tall, sound trees but a low percentage of successful grafts, averaging but 32 as against 46 Americana and 44 Peach. Attention is called to the fact, however, that these results are averages and that actual quality and vigor of the stock often exert a greater influence than its botanical name.

A review of Americana plums, F. A. WAUGH (*Vermont Sta. Rpt. 1902, pp. 260-265, pls. 4*).—Of the different groups of American plums, *Prunus americana* is considered by far the most important. The various types of American plums are briefly reviewed and their botanical names given, with the principal synonymy. At the present time there are about 200 named varieties of American plums. Many of these, however, are indistinguishable from each other. Lists are given containing the names of varieties of (1) proved value, (2) those of doubtful value requiring further test, and (3) culls or varieties which should be discarded.

The Japanese hybrid groups of plums, F. A. WAUGH (*Vermont Sta. Rpt. 1902, pp. 265-267*).—In a previous report (*E. S. R.*, 14, p. 44) the Gonzales group of hybrid plums containing Japanese blood was classified and named botanically. In the present report hybrids of the Japanese with the Americana and Simon plums are discussed. Hybrids between the Japanese and the Americana plums are classified as the Omaha group, using the variety of that name as the type of the group. The group is described and given the botanical name of *Prunus triflora rustica*. Hybrids of Japanese and Simon plums (*P. simonii*) are classified as the Wickson group and given the new name of *P. triflora reda*. In this group the variety Wickson is especially typical as regards fruit, and Bartlett as regards tree and foliage.

A résumé of what I know about my specialty—plums, J. W. KERR (*Trans. Peninsula Hort. Soc.*, 16 (1903), pp. 41-44).—The author states that wherever the peach is entirely hardy it is a very satisfactory stock for plums and that root grafting is incomparably superior to budding in propagating on this stock. The varieties Abundance and Chabot are considered the best of the Japanese or hybrid plums. Milton and Whitaker are considered the best among native plums. The author states that there is more profit in an acre of Milton plums than of any other variety.

Laying down of peach trees, W. PADDOCK (*Colorado Sta. Bul. 80, pp. 8, figs. 4*).—In many sections of Colorado peaches are destroyed 4 years out of 5 by late spring frosts. The methods of laying the trees down over winter and covering as a

protection are described. The practice of laying down is begun on trees the first years they are set in the orchard. Some time in November after the leaves have fallen a circle of earth about 4 ft. in diameter is removed from around the tree. Water is then poured in and the tree worked back and forth until the roots are loosened and the tree bent to the ground in the direction of least resistance. The branches are then tied together and the tree covered with burlap held in place with earth. A light layer of earth is then thrown over the tree. As the blossom buds begin to open the following spring the covering is loosened to admit of light and air. The blossoms are exposed to the sun gradually and after all danger from frost is considered over they are raised to an upright position and held in place by a couple of props. In placing the trees in the upright position the ground is again watered and when wet enough the trees are raised without difficulty. Old trees can not be very successfully handled in this manner. The practice must be begun with the young trees and continued. It is stated that the process seems to be in no way detrimental to the health of the trees since they live as long and bear as much fruit according to the size of the top as those grown in peach sections. The author believes that by laying down the trees in winter according to the plan outlined, peaches may be grown in nearly all parts of Colorado.

A remarkable pineapple (*Queensland Agr. Jour.*, 12 (1903), No. 4, p. 254).—A curious pineapple having the characteristics of the smooth-leaved Queen and the ordinary rough-leaved pine is described. The fruit is described as being full of seeds, the juice very abundant but of poor flavor.

A remarkable mango (*Queensland Agr. Jour.*, 12 (1903), No. 4, p. 254, pl. 1).—A mango fruit having a kind of horned protuberance is described. The fruit is borne on a tree between 4 and 5 years old and yields quite abundantly. The description is accompanied by a full-page illustration of the fruit.

Report of central station at Ames, H. C. PRICE (*Trans. Iowa Hort. Soc.*, 37 (1902), pp. 219-221).—Notes on the crosses made between varieties of apples, plums, and cherries, and on the distribution of orchard pollen among fruit growers. An experiment in stratifying whole fruits in sand out doors, stratifying the core of the apple containing the seed, and stratifying the seed after they have been removed from the apple resulted in favor of removing seeds entirely from the pulp before stratifying.

An Iowa plant breeder; some of his creations, H. C. PRICE (*Rural New Yorker*, 62 (1903), No. 2776, pp. 277-279, figs. 3).—An account, with illustrations and descriptions, is given of the varieties of crab apples, grapes, and dewberries originated by Newton K. Fluke in Iowa.

The influence of stock on scion, LACLERC DU SABLON (*Compt. Rend. Acad. Sci. Paris*, 136 (1903), No. 10, pp. 623, 624).—A pear grafted on a quince produces larger fruit and yields more abundantly than when grafted on pear seedlings. The author studied one of the causes of this phenomenon. He found that the reserve material accumulated during the autumn and winter in the trunk and limbs was considerably greater in the pear grafted on the quince than in trees grafted on pear seedlings. In the spring, therefore, when growth starts, the trees grafted on quince are better able to contribute to the formation of fruit a large quantity of food than trees grafted on pear seedlings. No cause could be assigned as to why more starch should accumulate in the trees grafted on quince than in the trees grafted on pear seedlings.

Hardiness of some grafted stocks, J. M. GUILLON (*Rev. Vit.*, 19 (1903), No. 482, pp. 301-305, figs. 5).—An account of the growth of several species of grafted stocks in shallow and deep soils.

Comparative structure of calluses in grafted plants, L. DANIEL (*Rev. Vit.*, 19 (1903), No. 482, pp. 324, 325).—A microscopical study of the calluses of a large number of grafted plants.

Grafting nutmegs (*Agr. News [Barbados]*, 1 (1902), No. 6, p. 84).—Detailed directions are given for grafting nutmegs.

The white blackberry "Iceberg" (*Sci. Amer.*, 88 (1903), No. 19, p. 358, fig. 1).—An account of the origination by Luther Burbank of a white blackberry. The fruit is white and of good quality, being as firm when ripe as Lawton. The plant is said to be very productive.

Unfruitful currants, EWEERT (*Gartenflora*, 52 (1903), No. 8, pp. 210-218, figs. 6).—The author made an investigation of certain varieties of currants that flowered profusely but failed to produce fruits. The flowers were first examined as to the amount of nectar they might contain, when it was found that the amount of dextrose in flowers of unfruitful sorts was practically equal to that in fruitful varieties. The pollen of the unfruitful sorts was found to germinate in a 3 per cent sugar solution containing $1\frac{1}{2}$ per cent of gelatin. The pistils of a large number of varieties were then examined and it was found that while the pistils of the unfruitful currants were practically as long as any of a number of other varieties, the width was very much less. Drawings are given showing the difference in the appearance of the stigmas of sterile and fruitful currants, and the opinion is expressed that the sterility in the case under observation was largely due to some malformation of the pistils.

Grafts in moss, R. C. DE BRIAILLES (*Prog. Agr. et Vit. (Éd. L'Est)*, 24 (1903), Nos. 10, pp. 308-310; 11, pp. 326-333, figs. 4).—An account of the handling of grape bench grafts. As soon as the grafts are made they are placed in boxes containing a layer of moistened moss and charcoal mixed in the proportion of 1 of charcoal to 3 of moss. A layer of this mixture about 10 cm. deep is placed in the bottom of the box. The grafts are then put in and surrounded with a layer of the mixture about 5 cm. thick. The top of the grafts are covered over with cut moss and charcoal 6 to 8 cm. deep. Boxes of grafts thus prepared when covered are ready for shipment. In the future care of these grafts the boxes are placed in warm rooms having a temperature of 30 to 35°. Within about 24 hours thereafter the buds begin to swell; in 4 or 5 days they lengthen rapidly, and within 8 days have a length of several centimeters. At this time the layer of moss over the grafts is removed completely and the condition of the growing buds noted. If all is going well a layer of recently prepared chopped moss and charcoal about 2 cm. deep is replaced over them. If any appear to be rotting these are left exposed for about 24 hours and then covered. If transpiration is taking place too rapidly in some portions of the box a thicker layer of moistened moss and charcoal is placed over them. The plants are watered by placing the boxes in a tank so that the water rises through holes in the bottom nearly up to the callus. The water should have the same temperature as the room. No water is applied above; since it is likely to cause mildew and rotting. Watering from below is practiced about every 8 days. Within 15 to 20 days the grafts will have become well calloused and a considerable leaf growth have appeared. The plants may be then hardened off as rapidly as desired and transplanted to the field.

Some of the advantages of growing grafts in moss rather than out of doors are as follows: The work of grafting is simplified, the grafts being put in boxes as soon as made and no tying required; a degree of vegetation is attained in 20 days that in outdoor practice would require about 2 months; a more perfect callus and union is obtained; disbudding of the stock is unnecessary.

Grape pollen and pollination, F. H. HALL, S. A. BEACH, and N. O. BOOTH (*New York State Sta. Buls.* 223 and 224, popular ed., pp. 8, pls. 2).—This is a popular edition of these bulletins (*E. S. R.*, 14, pp. 869, 870).

The use of plaster in viticulture: Its application in connection with manures, L. GRANDEAU (*Jour. Agr. Prat., n. ser.*, 5 (1903), No. 14, pp. 432-434).—Experiments extending over a number of years are reported. These showed that applications of gypsum alone or in connection with barnyard manure largely increased the yield of grapes.

Direct shipments of grapes from Spain, A. E. CARLETON (*U. S. Consular Rpts.*, 72 (1903), No. 273, pp. 81, 82).—Notes on the shipment of fresh grapes from Spain to the United States and possibilities of the further development of this trade.

Fertilizing by means of leguminous plants applied to tea culture, A. E. KERKHOVEN (*Teyssmannia*, 13 (1902), No. 1, pp. 15-21).—The experiments first undertaken in 1899 have not been definitely completed, but the author gives the results of work done up to January, 1902. Small tea plantations were fertilized with various commercial fertilizers, with stable manure, and by planting with a native leguminous tree called "dadap." The results so far obtained indicate that the first effect of the planting of "dadap" in the tea plantations is injurious because of the shade, but that the subsequent influence is more beneficial than the heaviest application of stable manure. This is due to the nitrogen stored in the root nodules.

Experiments were also made to learn how the leguminous shade tree should be treated to minimize the injurious effects of the shade and at the same time to retain the advantages of the nitrogen-gathering properties of the tree. The best practice appears to be to prune the tree heavily, so as to reduce the shading and also to encourage the tree to renewed growth and thus extend the root system.

Observations were also made on the influence of leguminous shade trees on plantations of cinchona and *Ledgeriana* trees, and it was noted that when the plantations were shaded with *Albizia* they remained in good health for a longer time than when not so shaded. The stems, though more slender, were longer and yielded more bark under shade than without it.—H. M. PIETERS.

Fruit storage experiments (*Illinois Sta. Circ.* 67, pp. 3-10, 21-23, fig. 1).—A report of progress is given on the cold-storage work with apples which is being carried on in Illinois under the direction of the station. An account of the construction of a cold-storage house, capable of holding 2,500 bbls. of fruit and of storing apples in cellars insulated for the purpose, has been previously noted (*E. S. R.*, 14, p. 356). During the season of 1901-2, 2,000 bbls. of fruit were placed in the cold-storage house October 5 and 70 tons of ice put in the refrigerator. The temperature of the storage room fell rapidly after the ice was put in to about 33° F., and this temperature, or a little lower, was maintained throughout the experiment. The cost of storage per barrel of fruit up to April 23 (about 7 months) was 19.1 cts., or 30.9 cts. less than the usual charge for apple storage. Based upon these results it is estimated that the building if stored to its full capacity each year would pay for itself in 5 years.

The fruit in the building was examined from time to time during storage. Without exception the fruit kept well. "There was no scald, no withering. The fruit remained plump and in perfect condition, and the percentage of rotten fruits was very small." The results are believed to plainly show the utility of buildings of this character cooled by ice. "Commercial growers of apples can well afford to invest in similar houses and thus add greatly to their profits." The experiences in cellar storage in southern Illinois show pretty clearly that horticulturists can not afford to insulate a cellar for storing fruit. The earth is too good a conductor of both heat and cold. Fruit stored in these cellars was more or less wilted and the percentage of rot was quite high.

Experiments were made with Ben Davis and Winesap apples in storing at temperatures of 31, 33, 35, and 37° F. The Ben Davis variety kept better and scalded less at 31° than at any other temperature. The difference was not so striking with the Winesap variety, but was in favor of the lower temperatures.

Another problem investigated was the degree of maturity most suitable for picking apples to be held in cold storage. The results obtained indicate a great superiority in the keeping qualities of mature over immature fruit. The mature fruit in storage showed a much smaller percentage of rot, was less subject to scald, did not shrink as much, had better color, and better selling qualities when removed from storage.

Notes are given on an experiment in orchard drainage and fertilization under way, and of the growing of a number of different cover crops in the orchard.

Cold storage, H. T. GALPIN (*Jour. Soc. Chem. Ind.*, 22 (1903), No. 6, pp. 346-348).—A technical account of the use of different brines for producing cold and of

the various problems involved in cold storage. Calcium chlorid is believed to be a much better solution for producing cold than common salt, and it has the further advantage of not freezing at even 50° below zero. A 30 per cent solution will freeze at about 54° below zero. For ice making, where a brine temperature of 10 to 20° F. is carried in a tank, a brine ranging from 12 to 18 per cent is all that is required.

Some remarks on the canning industry, and details of processing fruits and vegetables, W. B. ALWOOD (*Virginia State Hort. Soc. Rpt. 1902, pp. 202-216*).—A discussion of the importance of the canning industry, buildings and equipment, contracting for growth and delivery of crops, principles underlying the processing of canned goods, germs which cause fermentation and putrefaction, critical temperatures, and crops commonly canned in Virginia.

Report of the Nova Scotia School of Horticulture, F. C. SEARS (*Rpt. Sec. Agr., Nova Scotia, 1902, pt. 1, pp. 70-90, figs. 8*).—A brief report is given of the work of the school during the year, with lists of orchard fruits and of the principal trees and shrubs, including climbers, roses, etc., planted at the school, and an account of various experiments in orchard culture and the treatment of apple canker. Crimson clover and tares have been found very effective orchard cover crops, as well as alfalfa. Twelve model orchards have been established in as many different counties in the province during the year. In 5 of these orchards experiments were made in cutting back the fruit trees at the time of setting in the orchard. Five trees in each orchard were pruned in the usual way and 5 allowed to grow without pruning. The results for the season were generally in favor of cutting back the limbs at the time of setting in the orchard. Some data are given showing the number of trees of different varieties of apples affected by canker, from which it appears that Ribston Pippin, Nonpareil, and King of Tompkins are specially subject to this disease.

The American carnation; how to grow it, C. W. WARD (*New York: A. T. De La Mare Printing and Pub. Co., Ltd., 1903, pp. 296, pls. 5, figs. 94*).—This is a comprehensive work on the culture of carnations in America. Various chapters deal with the origin and early history of the carnation, soils, fertilizers, greenhouse and field culture, diseases and insect pests, greenhouse heating and management, raising carnations from seed, cross breeding, etc. Sketches are given of methods of carnation culture in different sections of the country, with brief biographical sketches of 10 prominent carnation growers in those sections.

Breeding hybrid carnations, C. W. WARD (*Proc. New Jersey State Hort. Soc., 28 (1903), pp. 227-233*).—The author secured better results by breeding between varieties originating from a common source than between varieties of widely different origin. Working along this line, colors were definitely fixed and finally bred upon plants of definite habits of growth and freedom of bloom. The first colors fixed in the author's work were of the crimson varieties General Gomez, General Maceo, Governor Roosevelt, President Roosevelt, Octaroon, Creole Beauty, etc. For the purpose of systematic work, carnations were divided by the author into 10 different groups based on color. The crimson section has been so well fixed that good varieties can be produced from seed. Experimental crossing in the pink and white sections has resulted in fixing these sections fairly well, but attempts to fix the yellow and white variegated type, as well as the fancy and purple and blue sections, have not been very successful. The greater number of plants grown from cross-fertilized seed contain the dominant characteristics of both parents. In many instances 90 to 95 per cent of the seedlings held to the dominant color, and in some cases even 100 per cent held true to the color of both parents.

So far as the author has been able to judge "the pollen parent, apparently, has no positive determinating influence upon the color, the color of the seed parent prevailing fully as much in the progeny as that of the pollen parent. But where the desired color predominates in several generations of the ancestry of both parents it is comparatively easy to reproduce it. The seed plant also apparently has no positive determinating influence upon the habit."

In breeding carnations the continuation of a series of experiments was frequently interrupted by the production of plants producing neither pollen nor seed. Again, other plants might produce seed but no pollen, and vice versa.

The chief advancement in carnation culture during the past 70 years, in the author's opinion, has been in the improvement of cultural methods, and the growing of improved hybrids and varieties which do not burst the calyx in growing.

The fertilization of chrysanthemum flowers (*Rev. Hort. [Paris]*, 75 (1903), No. 9, p. 195).—It is stated that chrysanthemum flowers with small heads will yield a larger quantity of seed than flowers with large heads. In hybridizing chrysanthemums it is believed that better results will be obtained if the plant employed as a mother has both large and small heads. Pollen should be taken from plants grown naturally, that is, not pruned or disbudded.

Soil for blue hydrangeas, E. ANDRÉ (*Rev. Hort. [Paris]*, 75 (1903), No. 3, pp. 55-57).—Hydrangeas sometimes produce red and sometimes blue flowers. The reasons for this have not been definitely known. The author states that the soil coming from near Angiers and composed of granite, schist, sand, and considerable quantities of iron, and covered with a thick turf formed of decomposed vegetable matter, always produces blue hydrangeas. This soil is sold to horticulturists in different parts of France as a blue hydrangea soil. If, however, the roots of hydrangeas potted in this soil are permitted to permeate ordinary soil the flowers produced are likely to be of a red or dirty violet color. The author analyzed this soil, obtaining the following results:

Analyses of soil used for growing blue hydrangeas.

Physical analysis.	Percent.	Chemical analysis.	Percent.
Pebbly	24.00	Nitrogen	0.4103
Black silicious	61.80	Phosphoric acid1168
Clay	2.16	Lime0504
Calcareous09	Magnesia2000
Organic matter	7.55	Potash0850
Humus91	Soda0043
Water	3.49	Iron oxid	3.4100
	100.00	Sulphuric acid0857

It is seen that this soil is essentially silicious, very rich in organic matter and in humus, quite poor in nitrogen and phosphoric acid, and excessively poor in lime and potash. This analysis is believed to demonstrate that the presence of iron in the soil is not the only unique factor in the production of blue hydrangeas, but that there should be in addition an exclusion of lime. With the knowledge of the composition of soil in which blue hydrangeas flourish, it is now believed that it will be possible to synthetically produce a soil that will grow blue hydrangeas.

Blue hydrangeas (*Rev. Hort. [Paris]*, 75 (1903), No. 5, pp. 114, 115).—Observations are given which show that when débris from a slate roof was mixed with the soil, the color of the hydrangeas grown in such soil was blue. Where the broken slate was absent the color was red.

Nicotiana hybrids of the second generation, G. BELLAIR (*Rev. Hort. [Paris]*, 75 (1903), No. 3, pp. 54, 55, figs. 4).—The author pollenized *Nicotiana sylvestris* by *N. tabacum* in 1901. The hybrids obtained were all similar in character. Seed obtained from these plants was planted in 1902. The resulting crop varied greatly resembling neither the original parents nor the hybrids of the first generation. Four distinctive types obtained are described. One type resembled *N. virginica*, two were profusely flowering sorts, and the fourth type was noticeable on account of the color and unusual proportions of the flowers.

Etherization and chloroforming of dormant plant parts, W. JOHANSEN (*Norsk Høvetidende*, 18 (1902), No. 12, pp. 194-203, figs. 5).—The method of etheriza-

tion and chloroforming of dormant plants worked out by the author for the purpose of shortening the resting period and thus accelerating the forcing of plants, flowers, bulbs, etc., is described in outline in the paper. The plants are placed in an airtight etherization chamber lined with tin foil or with soldered sheet zinc; a layer of 2 to 3 cm. of dry sand is placed at the bottom of the chamber; when this has been carefully closed ether is poured in through a funnel at the top of the box and caught in a dish suspended directly under the same. The most convenient temperature for conducting the etherization is 17 to 19° C. The higher the temperature the more violent is the action of the ether. The ether vapor is generally left to act on the plants for 48 hours; toward the end of the rest period 24 to 30 hours will be found sufficient. As to quantities of ether required, 30 to 45 gm. of ordinary sulphuric ether per hectoliter (26.4 gal.) of air space is used in case of different plants, viz, lilacs, 32 to 40 gm.; *Marie Legraye*, not to exceed 38 gr.; *Viburnum*, 38 to 40 gm.; *Prunus triloba*, *Amgdalus persica*, *Spiraea*, etc., 30 to 35 gm.; *Azalea mollis* and other deciduous plants, 30 to 35 gm.; *Pyrus "floribunda"* forms, *Staphylea*, *Deutzia*, and *Magnolia*, 35 to 40 gm.; lily of the valley (before planting), 30 to 35 gm. After the etherization the plants are preferably forced at once; it is not necessary to use as high temperatures for etherized plants as is ordinarily the case. As the flowers of etherized plants are apt to be of a paler color than those appearing later in not etherized plants, it is advisable to place the plants, after the buds have opened, at a temperature of 12 to 15° C., where a deep color is a desideratum.

Chloroform may be used in the place of ether for shortening the resting period of plants, but it acts much more intensely and must be used in smaller quantities; three-tenths of the quantities recommended with ether will suffice. The highly inflammable character of both ether and chloroform renders extra care necessary in handling the liquids, especially where the etherization method is used under commercial conditions.—F. W. WOLL.

A woman's hardy garden, HELENA R. ELY (*New York: The Macmillan Co., 1903, pp. XVI+215, pls. 49, figs. 4*).—This book presents in a popular manner methods of planting home grounds with hardy flowers and shrubs. Directions are given for laying out borders and planting with annuals, perennials, biennials, etc. A feature of the book is that in carrying out the work no greenhouse, hotbed, or cold frame is required.

How to make school gardens, H. D. HEMENWAY (*New York: Doubleday, Page & Co., 1903, pp. XVI+107, pls. 8, figs. 16*).—This is a popular work dealing with the details of making a school garden, such as laying out beds and planting seeds, sowing seeds in window boxes, making cuttings, grafting, and budding. A short bibliography of school-garden literature is appended.

The nature study idea, L. H. BAILEY (*New York: Doubleday, Page & Co., 1903, pp. 159, figs. 2*).—"An interpretation of the new school movement to put the child in sympathy with nature."

FORESTRY.

A German method of oak reproduction, W. F. HUBBARD (*Forestry and Irrig., 9 (1903), No. 4, pp. 199-202, pls. 3*).—A description is given of a method followed in Germany for the substitution of oak forests for beech. The demand for beech timber is a depreciating one, while that for oak is continually increasing and the method described was devised in the neighborhood of Karlsruhe. A portion of the beech forest is annually cut over and put in oak in the following manner: In the autumn before cutting and while the trees are still standing the ground is strewn with acorns which are superficially worked into the ground with picks or mattocks. After the acorns have been scattered and worked in the forest is cut clean, the lum-

bering operations serving to still further work the seed into the ground. The succeeding year the ground is heavily covered with a germination of oak and birch, the latter coming in of its own accord. The birch acts as an excellent nurse crop, since it grows faster than the oak and protects the oak seedlings from frost and sudden evaporation. By the time the seedlings are 6 years old they form a complete cover and very dense stand. At this time the poorly developed oaks are topped, the dead ones removed, and the birches cut away. The subsequent growth of the oak trees is looked after, and straight well-developed trunks secured by a continual pruning. At the age of about 50 years the whole area is to be underplanted with beech or spruce to protect the soil, and the oak allowed to develop as a high forest.

The cultivation of the locust tree, L. R. JONES and W. J. MORSE (*Vermont Sta. Rpt. 1902*, pp. 239-243, fig. 1).—The authors recommend for certain types of sterile soil in Vermont the cultivation of the locust tree (*Robinia pseudacacia*). In 1897, 100 seedling trees were set in rows 4 ft. apart each way. At 11 years old they averaged 16 ft. in height and 5 in. in diameter. Encouraged by this small planting 5,000 more seedling trees were planted in 1902 and 92 per cent of the trees were alive at the time of the report and making rapid growth. This planting was made at a total expense of from \$27 to \$32 per acre. Estimates are made of the possible value of the crop which it is believed at the twentieth year will be about \$256 per acre. Suggestions are given for planting, and where there is danger from attacks of insects mixed plantations are recommended in which white and pitch pines, birch, elm and box-elder are believed valuable.

The black walnut, G. O. GREENE (*Industrialist*, 29 (1903), No. 15, pp. 231-238).—An account is given on the distribution and value of the black walnut, and notes are given on the rate of growth of a number of trees of known age which have been measured in different parts of Kansas. On account of the high price of walnut lumber the author argues that the planting of black walnut trees could be made a profitable investment.

Notes on *Pseudotsuga glaucescens*, G. BELLAIR (*Rev. Hort. [Paris]*, 75 (1903), No. 9, pp. 208, 209, figs. 2).—A description is given of *Pseudotsuga glaucescens* which is said to have been derived from the Douglas fir (*P. douglasii*) but is held to be sufficiently distinct to warrant its separation as a species.

A research on the eucalypts, R. T. BAKER and H. G. SMITH (*New South Wales, Dept. Pub. Instr., Technolog. Mus., Tech. Education Ser. No. 13, 1902*, pp. XI+295, pls. 46, dgm. 1).—The results of an extended study of the genus *Eucalyptus* are given in which the authors treat the systematic classification, hybridization, and evolution of species, together with their description, and the essential oils produced by them. The species described, of which there are more than 100, are grouped into 8 classes based according to the chemical constitution of the oils contained in their leaves. Special studies are reported on the different constituents of the oils, and the timber and forest characteristics of the different species are briefly mentioned.

A revision of the genus *Eucalyptus*, I, J. H. MAIDEN (*Sydney: Gort.*, 1903, pp. 48, pls. 4).—The author has begun a critical revision of *Eucalyptus*, which is without doubt the most important genus of forest trees in Australia. The general habits of the trees are described and their value as timber as well as their economic production is shown. The characters which have been used at different times to aid in the classification of the species are mentioned, and a study reported of *Eucalyptus pilularis* and *E. pilularis muelleriana*. These species are technically described, and their characters as forest trees and the value of their timber shown.

Progress in national forestry, J. S. PEYTON (*Forestry and Irrig.*, 9 (1903), No. 4, pp. 194-197).—A review is given of the forest reserves in the United States and their management.

Recent forest reserve consolidation (*Forestry and Irrig.*, 9 (1903), No. 2, p. 60).—By Presidential proclamation the Teton, Yellowstone, and Absaroka forest reserves

have been consolidated, the total area embraced by the present reserve being about 7,200,000 acres.

Forestry for southern New England wood lots, R. T. FISHER (*Forestry and Irrig.*, 9 (1903), No. 3, pp. 120, 121).—When taken as a whole southern New England is said to be more or less covered with an immature growth of mixed hard woods. Few stands are to be found where the trees are more than 60 years old, and fully 75 per cent are of sprout origin. In many places comparatively worthless species of trees have taken possession of the ground to the exclusion of more valuable ones. In order to determine the proper management of these areas the Bureau of Forestry of this Department has caused surveys to be made of 25 tracts in southern New England, and a working scheme has been devised for each. The object in view was to bring the grown-over wood lands into a productive condition. In suggesting methods of treatment an essential consideration was to make the forest have a permanent value to its owner. What is chiefly required for success in these regions is a knowledge of the results to be desired and the ways of bringing them about. Extensive investigations have been carried on in this line which are to be published in a future bulletin of the Bureau of Forestry of this Department.

Forestry at an experiment station, W. MULFORD (*Forestry Quart.*, 1 (1903), No. 3, pp. 81-86).—A description is given of the forestry work which has been taken up and developed at the Connecticut State Station. This work was largely the result of legislation which directed the appointment of a State forester and placed in the control of the experiment station the purchase and planting of such lands in the State as are suitable for the production of oak, pine, or chestnut lumber. Under the call for offers of land at a price not exceeding \$4 per acre, 24 tracts were offered aggregating about 7,000 acres. These have been examined and negotiations for their purchase are in progress.

The farm wood lot in Michigan, F. G. MILLER (*Forestry and Irrig.*, 9 (1903), No. 4, pp. 187-189).—Attention is called to the rapid deforestation of the northern parts of Michigan, and the value of the wood lot particularly in the southern portion of the State is indicated. In the southern part of the State the wooded area is rapidly decreasing, and with the increased value of forest products the author believes that under proper management the wood lot could be made a source of considerable revenue. The preservation and proper management of the natural wood lot as it now exists is said to be more important than artificial plantations, and for the management of such areas the author recommends the system adopted in the management of a successful wood lot in Pennsylvania. This consists of the removal of all dead, diseased, or otherwise undesirable trees, thinning as the trees become crowded, pruning and trimming to secure straight, clear stems, and the underplanting of all vacant and thin spots with some valuable tree, usually the white pine.

Minnesota's system of preventing forest fires, C. C. ANDREWS (*Forestry and Irrig.*, 9 (1903), No. 2, pp. 84, 85).—The Minnesota system for preventing forest fires is now in operation over about 9,000,000 acres of forest lands, and the execution of the law is placed in the hands of the town supervisors who are made fire wardens. A chief fire warden is provided for by the law and it is made his duty to investigate the various aspects of forestry and report annually to the proper State authorities. The present appropriation for carrying out this law is \$5,000, and a scale of compensation is given by which citizens who are called upon to help extinguish or control fires are remunerated. A considerable part of the expense of fighting fires is charged against the county, and the writer thinks that the law would be more effective if the State should pay two-thirds of the expense and the counties one-third.

The most profitable trees for planting on the waste lands of farms in New Jersey, F. R. MEIER (*Proc. New Jersey State Hort. Soc.*, 28 (1903), pp. 208-215, pl. 1).—According to the author, there is considerable land in New Jersey which is not adapted to general agriculture and it is thought possible that it may be made more

productive by planting it with trees. Some of these areas are described, and the planting of willow, cottonwood, black locust, black walnut, tulip tree, yellow and white pines, and white cedar is recommended. Particular stress is paid to the planting of willows for osier purposes. The methods for preparing the ground are described, as well as the distance of planting, and subsequent cultivation and preparation for market. A report is given of a 15-acre osiery planted 8 years before at an expense of \$73.60 per acre which yields annually a net profit of \$85 per acre.

Forestry in Ohio, W. R. LAZENBY (*Forestry and Irrig.*, 9 (1903), No. 2, pp. 99, 100).—According to the writer, less than 14 per cent of the area of Ohio is forested and the destruction of this small proportion is still going on. Attention is called to the desirability of retaining forests, and forest planting for timber, shelter, and ornamentation is recommended. The different kinds of lands and different methods of planting for these purposes are described. In order to foster scientific foresting the author recommends the exemption from taxation of a certain percentage of wood land on each farm, the appointment of a State commissioner of forestry, the establishment of a school of forestry in connection with the State university, the establishment of a State arboretum where every species of forest tree could be grown, and the securing by the State of large tracts of cheap lands to be managed as State reserves for permanent forests.

Conservative lumbering at Sewanee, Tennessee, J. FOLEY (*U. S. Dept. Agr., Bureau of Forestry Bul.* 39, pp. 36, pls. 12).—An account is given of the results of the management of the forest owned by the University of the South, at Sewanee, Tenn., the work being carried on under direction of the Bureau of Forestry of this Department. The forest in question had been badly used and was steadily declining in value. In 1900 the Bureau of Forestry undertook its management, the principal condition being that it should be done at no cost to the university. A plan of management was devised which has proved profitable and has left the forest in good condition after lumbering. When the cooperative plan was begun a conservative estimate of \$3,000 was the value placed upon the timber. Under the plan of management a net profit in 1900-1 of \$1,500 was secured, the following year about \$1,200. It is said that 4 years more of lumbering remain to be done and for at least 3 years the annual profit should be about \$1,500 a year, making the forest yield a profit of about \$7,000 from timber formerly valued at \$3,000. These profits were made possible through the careful planning of the lumbering in order to prevent waste and to secure the largest returns from the merchantable trees. In all the cuttings provision was made that the land should again produce valuable timber.

The report describes the forest in detail, enumerating the various species of trees, their characteristics and distribution, and gives recommendations for the future management of the tract. The recommendations can not be considered specific for the management of similar tracts in other regions of the South. The effects of fire, overgrazing, insect injuries, and improper cutting are described, and the methods of lumbering which were adopted are given at considerable length.

Evidence taken before departmental committee of the board of agriculture on British forestry (London: Wyman & Sons, Ltd., 1903, pp. 117+241, dms. 4).—This consists of the evidence taken before a departmental committee appointed by the board of agriculture to inquire into and report upon the condition of British forestry. The general impression is given that the management of British forests is unskillful and that it could be readily improved. This condition is due to a great degree to the fact that the wood lands are not always planted or managed for revenue, but often as game preserves or for ornamental purposes. The forests of Scotland on the whole are said to appear better than those in England, but, according to the evidence, while the planting in Scotland is to be commended there is much subsequent mismanagement. Public forests are well managed on the whole, as is shown by reports of the condition of different crown lands.

The effect of deforestation on climate is mentioned and attention called to the fact that the forest area of Great Britain is considerably smaller than is believed to be the proper proportion for the best agricultural conditions. Considerable attention is paid to the subject of planting, in which it is shown that the cost of planting ranges from \$7.20 to \$20 per acre, as it appears from the returns from a number of large plantations. Among the species suggested for extensive planting the Scotch fir and larch are generally recommended, although the larch suffers considerably by disease. In addition to these trees a number of species of pines, as well as silver fir, cedar, and hard woods, are recommended.

In the appendices supplemental statements are made on a number of subjects, such as the relative merits of British and foreign timbers, the income from a mixed larch and fir wood at the end of its seventy-fifth year, receipts and expenditures from the clearance of an 18-acre mixed forest of about 75 years' growth, suggestions for the improvement of British forestry, outline of courses in forestry, description of various schools of forestry and their courses of instruction, timber tests of telegraph poles and cross arms, and area of crown forests in the United Kingdom.

Report of the forestry bureau July 1, 1901, to September 1, 1902, G. P. AHERN (*War Dept., Bureau of Insular Affairs, Philippine Com. Rpt. 1902, pt. 1, pp. 451-527, pls. 37, map 1*).—A detailed report is given of the progress made by the bureau of forestry during 1901-2. Numerous additions to the scientific staff are noted and also the organization of several new divisions and laboratories. The personnel of the scientific and administrative staffs is shown, the administrative staff consisting of 4 assistant inspectors, 10 assistant foresters, and 65 forest rangers.

Descriptions are given of the facilities provided for work in the different lines of investigation. Summaries are given showing the licenses granted between July 1, 1901, and August 31, 1902, for cutting timber, also the number of sawmills, employees, output, market value and income derived by the Government from all franchises for the utilization of forest products. The revenue derived during the time covered by the report was \$348,073.08 Mexican, the Government charges being between 5 and 10 per cent of the market price of the timber in Manila. Valuation surveys have been begun and the results already obtained indicate a conservative estimate of an average stand of 3,500 cu. ft. of timber 20 in. in diameter, on over 20,000,000 acres of virgin forest. The total forest area of the archipelago is estimated at 48,112,920 acres, less than 1,000,000 of which is held by valid private title.

The forests are described and their principal species indicated, together with their groupings under the forest regulations adopted by the bureau. A preliminary working plan of Bataan Province, prepared by R. C. Bryant, is given in which the necessary operations for conservative lumbering are described. Investigations by P. L. Sherman on the forest products of the islands are also reported, particular attention having been given to the gutta-percha industry, the permanency of which is threatened by wasteful methods of exploitation.

Progress report of the forest surveys in Bengal, India, 1901-2, P. J. GORDON (*Calcutta: Supt. Govt. Printing, 1903, pp. 17, map 1*).—A progress report is given of forest surveys in India for 1901 and 1902 in which the character of the survey is indicated, and the extent of the surveyed and unsurveyed forest area is shown. The cost of the survey by provinces is given. The survey during the period covered by this report was quite extensive, and attention is called to the fact that it will be impossible to continue the work at the present rate without more adequate provisions for carrying on the work.

The production of timber in Algeria, J. TRABUT (*Bul. Agr. Algérie et Tunisie, 9 (1903), Nos. 2, pp. 25-28; 3, pp. 55-59*).—A description is given of the forest conditions of Algeria, and attention called to the rapid disappearance of the Algerian forests wherever they occur in accessible regions. On account of the disappearance of trees of a size adapted to construction timber, the author suggests the artificial

planting and describes a number of species which either have been tried or are believed to be adapted to Algerian conditions.

The forester and the lumberman, G. PINCHOT (*Forestry and Irrig.*, 9 (1903), No. 3, pp. 176-178).—An address, in which the author points out the necessity for cooperation between the lumber industry and the scientific forester, in order to secure the greatest measured benefits to both. A review is given of the methods of forestry and some of the results already obtained in this country. Attention is also called to the forestry operations conducted under governmental authority in the Philippines.

A profitable cutting of insect-killed timber, A. CARY (*Forestry and Irrig.*, 9 (1903), No. 3, pp. 149, 150).—An account is given of a method of lumbering by which timber destroyed by bark beetles was profitably lumbered and at the same time the ravages of the bark beetles greatly reduced. The presence of the bark beetles in the spruce forests has been known for about 15 years, their ravages constantly increasing. In some tracts fully half the standing timber has been destroyed. The author arranged for the cutting of a considerable portion of dead timber, which belonged to the Berlin Mills Company, in such a way that the expense was not so great that contractors would be unwilling to undertake the lumbering. The ravages of the bark beetle appear to spread from centers, so that nearly all the trees in definite regions would be destroyed. By cutting these, together with enough green timber to justify the lumbering, it was found that contractors would undertake the necessary operations.

Preservation of soil fertility in plantations, A. C. FORBES (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 15 (1903), pp. 69-94).—An argument in favor of more attention to the preservation of fertility in the soil of forest plantations.

Shade tree suggestions, A. NELSON (*Wyoming Sta. Bul.* 57, pp. 14, pls. 5).—This bulletin is prepared to show what may be done in improving the conditions of Wyoming in the way of street, lawn, and other plantings, the principal object being to give impetus to the movement for the ornamentation of homes, municipal buildings, parks, etc.

Creosoting timber, S. W. LABROT (*Tradesman*, 49 (1903), No. 6, pp. 77, 78).—A description is given of the processes of treating timber by the zinc-creosote method. This consists in two operations—the sterilizing and drying of the timber and the forcing into the wood of the antiseptic chemical. In sterilizing the timber great care must be taken to avoid overheating, as excessively high temperatures have a very damaging effect upon the strength of the timber. This is particularly true of those which contain resinous substances. These resins are evaporated at about 305° F. and their removal greatly weakens the structure of the wood. After sterilization the chemical is forced into the wood under pressure, and in the method described zinc chlorid is mentioned as the cheapest and most common substance used in this country. Timber treated in this manner is said to have its durability increased by 12 to 16 years in the case of white pine railroad ties, or from 18 to 30 years in railroad structural timbers.

SEEDS—WEEDS.

Timothy, alsike, and red clover seeds, G. H. CLARK (*Canada Dept. Agr., Comr's Branch, Seed Division Bul.* 8, n. ser., pp. 30).—The purpose of this bulletin is to call attention to the trade conditions in timothy, alsike, and red clover seeds, and to give the results of analyses of more than 500 samples of seeds collected from various parts of Canada. A summary is given of the methods of seed testing and seed control that have been adopted in other countries, and other information which it is believed would be helpful to seed growers, merchants, and consumers. Inquiries were sent to a large number of correspondents from whom 513 samples were received

and subjected to the usual seed analysis. Tables are given showing the market price of different lots of seed, the percentage of germination, number of weed seeds, and the actual cost of the living seed per bushel. A list is given of 25 of the principal weed seeds found in the different lots of seed and the proportion in which they occurred in the different samples.

Seed-testing stations in Hungary, J. SPEIR (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 15 (1903), pp. 53-62, fig. 1).—An account is given of the organization of seed-test laboratories in Hungary, their equipment and methods are described, and results of tests shown. Tables are also given in which the rate of compensation demanded for making tests, together with the form of the report given for all seed testing, are shown.

Rules for seed examinations adopted by Danish seed control stations (*Tidsskr. Landbr. Planteavl*, 8 (1902), pp. 223-233).

Influence of the remedies employed in combating smut on the germination of seeds, B. MEZENTZOV (*Yuzh. Russ. Selsk. Khoz. Ghas.*, 1902, No. 42; abs. in *Zhur. Opitn. Agron. [Jour. Expt. Landw.]*, 3 (1902), pt. 6, pp. 738, 739).—The author presents results of experiments carried out on the Derebchinsk experiment field and at the Sobyeshinsk Experiment Station. Seeds were treated with copper sulphate solutions and were soaked with hot water. In one case the following results were obtained: (a) In dry earth there germinated: Nontreated seeds 80 per cent, soaked in copper sulphate solution 36 per cent, soaked in vitriol and washed with lime water 46 per cent, dipped in hot water 82 per cent. (b) In moist earth: Nontreated seeds 95 per cent, soaked in copper sulphate solution 75 per cent, soaked in copper sulphate solution and washed with limewater 85 per cent, steeped in hot water 96 per cent. Other series of experiments gave approximately the same results.—P. FIREMAN.

On the influence of salt water on the viability of seeds, O. ROSTRUP (*Tidsskr. Landbr. Planteavl*, 8 (1902), pp. 37-40).

On the viability of seed buried in the ground, O. ROSTRUP (*Tidsskr. Landbr. Planteavl*, 8 (1902), pp. 35-37; 9 (1903), pp. 27-29).

On the viability of weed seed, O. ROSTRUP (*Tidsskr. Landbr. Planteavl*, 8 (1902), pp. 33-35).—A cow was fed freshly cut weeds of different kinds and for 5 days the manure was examined for weed seeds. The viability of the weed seeds and other seeds found in 217 gms. of dung was subsequently determined. The total number of seeds and their viability are shown in the accompanying table:

Viability of weed seed from cow dung.

Name of seeds.	Total number of seeds.	Viability.	Name of seeds.	Total number of seeds.	Viability.
		<i>Per cent.</i>			<i>Per cent.</i>
<i>Solanum nigrum</i>	3,355	52	<i>Plantago major</i>	125	87
<i>Chenopodium album</i>	1,270	51	<i>Atriplex patula</i>	119	8
<i>Stellaria media</i>	377	49	<i>Veronica agrestis</i>	44	25
<i>Sonchus asper</i>	209	27	<i>Spergula arvensis</i>	44	9
<i>Senecio vulgaris</i>	191	5	<i>Polygonum aviculare</i>	31	35
<i>Thlaspi bursa-pastoris</i>	166	24	<i>Petroselinum sativum</i>	21	86
<i>Urtica urens</i>	164	11			

A large number of other seeds were identified, but being found in only small numbers the results of the determinations of viability can not be considered of general value. In order to ascertain whether the length of time during which the seeds remain in the digestive tract influences the results of the viability determinations, the germination of seeds of *Solanum nigrum* on subsequent days was determined, with results as follows: First day after feeding, 48 per cent; second day, 53

per cent; third day, 55 per cent; fourth day, 52 per cent, and fifth day, 5 out of 7 seeds germinated. The percentage viability of seeds does not therefore appear to differ whether the seeds take 1 or 5 days to pass through the digestive tract of the cow.—P. W. WOLL.

Notes on weeds, W. CARRUTHERS (*Jour. Roy. Agr. Soc. England*, 63 (1902), pp. 279-288, figs. 8).—Illustrated notes are given of a number of the more troublesome weeds to which the author has had his attention called by means of specimens received and inquiries regarding the habits and methods for eradication. A brief study is also reported on the British brome grasses and a key is added for the determination of the different species known to occur within the Kingdom.

Killing weeds in lawns, L. R. JONES and W. J. MOUSE (*Vermont Sta. Rpt.* 1902, pp. 243-248, figs. 2).—Notes are given on the destruction of chickweed and crab grass in lawns. For the destruction of chickweed raking the lawns or sowing them with salt, or both methods combined, were found effective when made the last week of June. The application of 2 qt. of salt to the square rod, followed by thorough raking of the chickweed and a liberal sowing of grass seed, was completely successful in exterminating chickweed and in securing a full stand of grass. It is suggested that where salt is used on a lawn it should be done cautiously on a small scale, as the effects will vary in different soils and seasons. For the eradication of the crab grass the authors suggest care in selection of seed to avoid the introduction of this plant, which is an annual; the use of grass seed, fertilizer, and water freely so as to keep the grass in vigorous growth; and the hand weeding of the crab grass if it should appear.

DISEASES OF PLANTS.

Report of the vegetable pathologist, D. McALPINE (*Jour. Dept. Agr. Victoria*, 1 (1902), No. 3, pp. 801-808, pls. 2).—Among the subjects reported upon an account is given of experiments on the resistance of varieties of wheat to the rust, and the fact is brought out that so far as economic importance is concerned the only rust occurring in Victoria is that known as summer rust (*Puccinia graminis*). So far as it has been determined this rust, which is very abundant in Australia, produces uredospores—which would retain their vitality only during comparatively mild weather—and teleutospores, but the relationship between the teleutospores and the subsequent production of rust has not been determined. Notes are also given on the treatment of grain for the prevention of stinking smut, formalin, copper sulphate, and corrosive sublimate solutions being used. The different solutions were efficient in preventing the occurrence of stinking smut, but the most satisfactory treatment was that where the seed was soaked for 10 minutes in a solution of 1 lb. of formalin to 100 gal. of water. Notes are given on the black spot of apples and pears due to *Fusicladium* sp., as well as the bitter rot of apples.

Attention is called to experiments for the prevention of a fungus disease of grasses. This fungus (*Isaria graminiperda*) is figured and described, and it is shown that a liberal application of nitrogenous manures, sulphate of ammonia being the most satisfactory, gave absolute exemption from attacks of the fungus. The application of the fertilizer not only prevented the occurrence of the disease but stimulated a greater production of forage.

The diseases of cultivated plants, G. DELACROIX (*Maladies des plantes cultivées. Paris: Min. Agr., 1902, pp. 73, figs. 81*).—Illustrated descriptive notes are given of a large number of diseases of cereals, potatoes, beets, forage plants, vegetables, orchard and vineyard fruits, etc., together with brief suggestions of the most approved methods of combating these troubles.

Notes on some important plant diseases of the Tropics, F. NOACK (*Ztschr. Pflanzenkrankh.*, 12 (1902), Nos. 4, pp. 227-234; 5, pp. 285-291).—Brief critical notes are

given on recent investigations in many tropical countries of some of the more important diseases of economic plants. Among those reviewed are the diseases and insects affecting coffee, cacao, tea, sugar cane, cotton, pineapples, bananas, citrus fruits, rubber trees, and cork oak.

Notes on some plant diseases, K. MALKOFF (*Ztschr. Pflanzenkrankh.*, 12 (1902), No. 5, pp. 282-285, fig. 1).—Brief notes are given on a number of diseases of plants which the author observed in the vicinity of Göttingen. The first described is the anthracnose of clover due to *Glaeosporium caulivorum*. The author claims that red clover grown from seed from different countries seems to be unequally affected, that from eastern North America being most subject to disease, while the south Russian, Polish, and Canadian was least attacked. In addition to the red clover, the author reports the fungus as attacking *Trifolium purpureum* and *T. medium*. The early mowing of clover fields is recommended to prevent the spread of the disease. A second disease which also attacks clover is due to the fungus *Macrosporium sarcinaeforme*. This fungus attacks the leaves, giving them a ragged appearance and later causing them to turn brown and fall from the plants. Inoculation experiments were carried on with cultures of this fungus which seem to demonstrate that it was due to this particular organism. The third disease described is that of leaf spot of rye, caused by the presence of *Rhynchosporium graminicola*. The extent of injury due to this cause was not determined.

The distribution of the anthracnose of red clover, G. LINHART (*Ztschr. Pflanzenkrankh.*, 12 (1902), No. 5, pp. 281, 282).—The distribution of *Glaeosporium caulivorum*, the cause of clover anthracnose, or stem browning, as it is called, is said to cover practically all of Europe wherever red clover is grown. The author says that plants grown from American or European seed suffer alike and in some places as much as 50 per cent of the plants were observed to be dead as a result of the fungus. Weather conditions are said to exert an important influence on the occurrence of the diseases, unusual wet weather greatly favoring its spread. So far as the author's observations go, alfalfa does not appear to be subject to this disease. The fungus attacks all of the above-ground parts of the plant, the stems and petioles in particular, causing them to turn brown as though burned. There is thought to be some evidence of the transmission of the disease by means of infected seed, and it is recommended that seed be treated with a 1 per cent solution of Bordeaux mixture before sowing.

Investigations on cereal rusts, E. MARCHAL (*Bul. Agr. [Brussels]*, 19 (1903), No. 1, pp. 114-153).—After briefly reviewing the present status of the cereal rust problem the author gives descriptions of the more common species which he has investigated. Among those described are the black rust (*Puccinia graminis*), brown rust (*P. triticea*), yellow rust of wheat (*P. glumarum*), brown rust of rye (*P. dispersa*), pale rust of barley (*P. simplex*), and crown rust (*P. coronifer*). Most of these rusts have specialized forms which are also described. Analytical keys are given for the determination of the kind of rust found upon a plant, and a tabulated statement is presented showing the distribution and frequency of occurrence of the different species in Belgium.

The author states that wheat is most frequently attacked by the brown rust, followed by the yellow and black rusts in order of frequency. The figures upon which this conclusion is based are the averages of observations made during 2 seasons although slight differences are noted, particularly in the relative occurrence of the yellow and black rusts. Upon the rye the principal species is the brown rust, the black rust being rather rare and spasmodic in its appearance. The common barley rust is the pale rust which was found present in 92 per cent of all the specimens examined. The black rust is frequent in certain years, while the yellow rust which is so destructive in Sweden is unknown in Belgium. The oats suffer most from the crown rust, and the black rust is comparatively rare. The varying susceptibility of

different varieties to disease is shown and the influence of soils, meteorological conditions, fertilizers, seeding, etc., on rust development are discussed. The rôle of barberry and boraginaceous and other plants on the alternate generations of the rust fungus is commented upon at considerable length. The losses due to cereal rusts are discussed and suggestions given for their prevention. Among the suggestions offered are the sowing of resistant varieties, early seeding, and rational fertilizing.

The treatment of stinking smut in wheat, J. REED (*Colorado Sta. Bul.* 79, pp. 8).—A description is given of the stinking smut of wheat caused by *Tilletia foetens*, and 2 methods of treating the seed for smut prevention are described. In these treatments the seed was either soaked or sprinkled with solutions of copper sulphate, corrosive sublimate, potassium sulphid, and formalin. The results obtained showed the efficiency of copper sulphate, corrosive sublimate, and formalin, and demonstrated that potassium sulphid, besides being very expensive, is not an efficient remedy. Sprinkling the solutions over the grain and thoroughly mixing by raking or shoveling is recommended as the quickest and easiest, as well as most efficient treatment.

Potato diseases and their remedies, L. R. JONES and W. J. MORSE (*Vermont Sta. Rpt.* 1902, pp. 209-230).—A report is given of the potato diseases as they occurred in 1901 and 1902, the results of spraying experiments, the relation of date of digging to development of potato rot, the effect of top pruning potatoes, and potato scab experiments. During 1901 and 1902 there was an unusual prevalence of the late blight and rot due to *Phytophthora infestans*, and the conditions are believed favorable for the destructive occurrence of the disease in 1903 unless the summer should be an unusually dry one. In order to prevent serious losses from this cause the authors suggest the selection and saving of seed from the earlier planted crop on light soils so that there will be as little fungus as possible introduced to the seed potatoes, and the thorough spraying of the plants with Bordeaux mixture during the season.

The spraying experiments reported were begun in 1901, comparison being made between Bug Death and a Bordeaux-Paris-green mixture. The results are given at some length, from which it appears that although Bug Death was used in very large amounts its inefficiency as a fungicide was demonstrated. During the second year the spraying experiments were continued but Bordeaux mixture and Paris green alone were used. The results of these experiments are shown and a tabular statement is given showing the average gain for 12 years attributed to the use of Bordeaux mixture on late potatoes. The average increased yield attributed to this cause was 115 bu. per acre.

While carrying on the spraying experiments during the summer the soil of certain rows was sprayed to ascertain whether this treatment would prevent the development of the spores falling upon the soil and reaching the tubers. The results obtained are not considered conclusive, and although there was some evidence of eradication of disease this method of spraying is not recommended as practicable.

The question of how soon blighted potatoes should be dug has been frequently asked the authors, and a series of investigations was undertaken to ascertain the proper time of digging. The size of the plats and the extent of the experiment are considered too limited to admit of generalizations, but it appears that there was usually a greater loss from the earlier digging. So far as the investigations go, they seem to show that where there is danger of potato rot it is best to delay the digging for 10 days or more after the tops have died.

The effect of top pruning was studied on account of the unusual luxuriance of the potato tops, especially where they had been properly sprayed. The common belief was expressed that such a growth would interfere with the production of tubers, consequently the stalks of alternate rows were clipped back so as to present only about a foot of growth above the soil. The yield from the different rows at harvest is shown, from which it appears that practically $\frac{1}{3}$ of the crop was sacrificed by the cutting of the tops.

Potato scab experiments were carried on during the seasons covered by the report in which the susceptibility of different varieties was tested. In 1901 11 varieties were tested and in 1902 14 varieties. A comparison of the results shows considerable difference in the behavior of the different varieties, and the results are such as to lead to the hope that scab-resistant varieties may be secured by breeding and selection. Disinfection experiments in which formalin, corrosive sublimate, and formaldehyde vapor were tested for scab prevention were carried on and, as in all previous trials, both corrosive sublimate and formalin solutions proved equally efficient. The experiments with sulphur fumes and formalin vapor are to be continued.

Diseases of the potato in Ireland, T. JOHNSON (*Jour. Dept. Agr. and Tech. Instr. Ireland*, 3 (1902), No. 1, pp. 8-21).—Attention is called to a number of diseases of potatoes which occur more or less abundantly in parts of Ireland, at times causing serious losses. The potato blight (*Peronospora infestans*) and the sclerotium disease (*Sclerotinia sclerotiorum*), as well as the bacterial and Rhizoctonia diseases of potato are described, and an account given of the attack of *Phellomyces sclerotiphorus* upon the potato. So far as the author is aware this fungus has not previously been observed in Great Britain, and while truly parasitic may cause considerable unsuspected damage to the potato crop. It gives rise to a skin disease or scab of the potato tuber, followed by the rotting of the potato. In the earlier stage the presence of the fungus is indicated by the appearance of white shining patches on the skin of the tubers, and later the epidermal layers peel off leaving the underlying tissues exposed to the rot fungi. The disease may be carried over from one crop to another by planting with infected tubers and care should be taken to exclude them when observed.

Notes are given on a number of diseases of other plants, most of which are of common occurrence.

Some diseases of the potato and of fruit trees, A. LINTON (*Jour. Khediv. Agr. Soc. and School Agr.*, 4 (1902), No. 5, pp. 197-208, pls. 4).—A description is given of a number of diseases of the potato and of various fruit trees that are caused by attacks of fungi, insects, or other animals. Among the diseases of the potato the most loss is occasioned by attacks of the early blight (*Macrosporium solani*). The early planting of potatoes, the use of less susceptible varieties, and spraying with Bordeaux mixture are recommended as preventive measures. The enemies of the fruit trees described are mostly insects, stem borers and scale insects predominating, with notes on peach-leaf curl, plum rust, grape downy mildew, etc.

A new fungus disease of potatoes, R. S. MACDOUGALL (*Trans. Highland and Agr. Soc. Scotland*, 5, ser., 15 (1903), pp. 312-319, figs. 4).—A description is given of a disease of potatoes caused by the fungus *Chrysophlyctis endobiotica*. This disease has been previously described (E. S. R., 14, p. 979), and attributed to attacks of this fungus as well as to *Oedomyces leproides*. The life history of the fungus is described, and its occurrence on the potato crop is said to have first been noticed in 1899. In 1900 it was less abundant, but in the following years was quite prevalent. It is characterized by a peculiar warty outgrowth in the tubers, and commences about July or August, developing with the potatoes. Infection is usually through the eyes of the tubers, and may result in warty excrescences that are sometimes even larger than the potato itself. The disease is likely to manifest itself most seriously in damp places, although no perceptible deficiency has been noticed in the crop. After the potatoes are dug there appears to be no further development of the disease, nor do the affected potatoes seem more liable to decay. In planting the seed tubers should be carefully examined, and all affected ones rejected.

A bacterial disease of sugar beets, G. G. HEDGCOCK and H. METCALF (*Ztschr. Pflanzenkrankh.*, 12 (1902), No. 6, pp. 321-324).—A description is given of a disease of sugar beets which was recognized by the authors in various parts of Nebraska during the autumn of 1901 and later reported to them as occurring in Arizona and Colorado. As a result of the attacks of the bacteria the roots begin rotting at their tips and later the leaves and all the above-ground parts of the beets become entirely infested. The

organism, which has been isolated and cultivated through various media, is described at some length. The bacterium seem to be somewhat similar to that described by Kramer as the cause of bacteriosis of beets, but differs in being anaerobic, growing upon gelatin and potatoes and developing a brown pigment with the evolution of gas on sugar-beet cylinders. The disease seems to be most prevalent in wet soils and it is possible that the draining of these soils would tend to the restriction of the organism.

Nematode diseases of bananas, sugar beets, etc., V. MOSSEMI (*La maladie vermiculaire*. Cairo: Inst. Français, 1903, pp. 40, pls. 3, figs. 4).—An account is given of nematode diseases of bananas, sugar beets, and a number of other economic plants which are caused by the presence of the nematode *Heterodera radiculicola*. The effect of these parasites upon their host plants is described, and a complete description is given of the organism and its life history. Mention is made of 31 families of plants, embracing more than 100 species, which are known to the author to be subject to the attacks of this nematode. The effect of the disease on the composition of sugar beets is shown by analyses, and suggestions are given for combating the trouble. These consist in sterilizing the soil wherever possible, the rotation of crops, submersion of land from irrigation ditches, use of certain fertilizers, naturally resistant varieties, etc.

Nematodes in out-of-door plants, A. OSTERWALDER (*Ztschr. Pflanzenkrankh.*, 12 (1902), No. 6, pp. 338-342, figs. 5).—The occurrence of nematodes in the leaves, stems, and flowers of a number of wild plants is mentioned, and their effect upon the appearance of the plant is described. The species of nematode most commonly observed was *Tylenchus devastatrix*.

Anagallis arvensis as a host plant for stem nematodes, C. J. J. VAN HALL and M. W. V. VAN BILJEVELT (*Tijdschr. Plantenziekten*, 8 (1902), pp. 144-149, pl. 1).—The authors found that *Anagallis arvensis*, a common weed, especially on the light soils used for onion and hyacinth culture, was a favorite host plant for the nematode *Tylenchus devastatrix* that is so injurious to the onion and hyacinth culture. This fact is thought to account for the difficulty of ridding infected land of the nematode, even after years of cultivating with immune crops.—H. M. PIETERS.

Some diseases of sugar cane in the West Indies, A. HOWARD (*Ann. Bot.*, 17 (1903), No. 66, pp. 373-411, pl. 1).—An account is given of the "rind" disease of sugar cane and also a root disease which is quite prevalent. The author claims that the Melanconium found on diseased sugar canes in the West Indies is not the cause of the rind disease, as has been claimed by other authors, but it is wholly saprophytic in its growth. The phases of *Trichosphaeria sacchari*, which are claimed to be identical with those of *Thielaviopsis ethacetica*, cause a disease of cane cuttings in the West Indies which is identical with the pineapple disease of cane cuttings in Java, and in addition the fungus is parasitic on the growing cane. The rind disease of the sugar cane in the West Indies is identical with that known as red smut in Java, and is caused by the fungus *Colletotrichum falcatum*. This fungus readily attacks ripening canes at wounds and at the old leaf bases, as well as the young canes which are capable of active growth. The Melanconium referred to above infects the canes at the points where they have been invaded by the Colletotrichum. The common root disease of sugar cane in Barbados is that caused by the fungus *Miracium sacchari*. Under certain conditions the mycelium of this fungus attacks the growing tissues of the roots, causing their destruction.

The gummosis of the sugar cane, R. G. SMITH (*Proc. Linn. Soc. New South Wales*, 27 (1902), pt. 1, pp. 21-47, pls. 2).—A description is given of the disease of sugar cane caused by *Bacterium vascularum*. The substance of this paper has been previously noted (E. S. R., 14, p. 876).

An ascobacterium from the sugar cane, R. G. SMITH (*Proc. Linn. Soc. New South Wales*, 27 (1902), pt. 1, pp. 137-145, pl. 1).—A description is given of *Bacterium sacchari*, n. sp., which has been noted elsewhere (E. S. R., 14, p. 876).

A gum-forming bacterium from *Eucalyptus stuartiana*, R. G. SMITH (*Proc. Linn. Soc. New South Wales*, 27 (1902), pt. 2, pp. 230-236, pl. 1).—A description is given of *Bacterium eucalypti*, n. sp., which is found in the saccharin exudate of *Eucalyptus stuartiana*. The occurrence of this organism has been previously mentioned (E. S. R., 14, p. 876).

The bacterial origin of gums of the arabin group, R. G. SMITH (*Proc. Linn. Soc. New South Wales*, 27 (1902), pt. 3, pp. 383-407).—A study was made of various gums to determine the possibility of their bacterial origin. Fresh material was obtained from *Acacia penninervis*, and from the twigs of this tree small portions of gum were removed, the exterior portion sterilized, and cultures made from the fragments. In nearly every case 2 forms of bacteria were found present. The first, to which the name *Bacterium acacie* is given, the author believes is the cause of the production of the principal portion of the gum found on this plant. This organism in the laboratory was found to form a gum which behaved in all its reactions the same as the natural gum. The formation of gum on this tree is considered a bacterial disease, the bacteria elaborating the plant juices into gum which resembles the gum arabic in its properties.

The second organism, to which the name *B. metarabinum* is given, is believed to produce the more insoluble gums which occur associated with the others. In conclusion the author states that gums of the arabin group occur not only in the Acacias, but among other plants, particularly certain Rosaceae, and he believes it probable that they are produced by the work of similar organisms to those described above.

Cucumber diseases, G. E. STONE (*Massachusetts Sta. Bul.* 87, pp. 29-42, figs. 8).—Descriptions are given of a number of cucumber diseases, particular attention being paid to those occurring on cucumbers grown under glass. Among those described are a leaf curl, in which the leaves assume a spherical form due to the inrolling of the wilted edges of the leaves; a stem curl, which is said to be a more pronounced form of the same disease; and a cucumber wilt, all of which are attributed to improper conditions of cultivation. Among the diseases caused by fungi are the anthracnose, downy mildew, timber rot, damping off, powdery mildew, nematode diseases, etc. These different diseases are described and preventive means suggested where such are known. The author recommends the fumigation of the houses before planting with sulphur or potassium cyanid. The sulphur treatment is less expensive, but for most purposes the cyanid is to be preferred. Either of the treatments will remove some of the more common pests of greenhouses, and it is believed that growers will find the practice of fumigation highly advantageous.

Orchard diseases and their remedies, L. R. JONES and W. J. MOISE (*Vermont Sta. Rpt.* 1902, pp. 230-239).—A description is given of the destructive presence of the apple scab fungus during the summer of 1902. Owing to the excessive amount of rainfall spraying was much interfered with, and in many cases where applications of Bordeaux mixture and Paris green were made early in June a rusting or russetting of the fruit was reported and in a few cases there was a decided spotting of the foliage. Similar troubles were reported during the season from a number of localities, and after a careful examination the authors reached the conclusion that the trouble is due primarily to weather conditions and is aggravated by the spraying. An inspection of the orchards of Grand Isle gave abundant evidence of gain from spraying, and while there was a serious amount of damage due to the russetting the quality of the well-sprayed fruit was much higher than that from the unsprayed. The experience derived during the season suggests that the strength of solutions should be varied to suit the period of growth, climatic conditions, and fineness of the spray. The coarser the spray the weaker should be the solutions, and in early spring stronger mixtures may be used than during the summer.

Studies are reported upon plum blight which have already been noted (E. S. R., 14, p. 880).

A destructive apple rot following scab, H. J. EUSTACE (*New York State Sta. Bul.* 227, pp. 367-389, pls. 9).—During the autumn of 1902 in western New York there appeared a white, mildew-like fungus upon apples which was associated with the scab which had been unusually prevalent during the season. There was no relation between the 2 fungi except that the apple scab, by breaking the epidermis, made it possible for the second fungus to infest the fruit. An examination showed that this new disease was caused by the fungus *Cephalothecium roseum*, a fungus which had hitherto been regarded as a saprophyte. A description is given of the organism and the effect which it produces, as well as statements regarding the susceptibility of various varieties to the disease. Rhode Island Greening, Fall Pippin, and Fameuse seemed more affected than any other varieties, the Rhode Island Greening suffering by far the most.

While the author's investigations were confined to western New York, replies which were received from a number of other localities indicate that the same trouble existed in Michigan, Ohio, and Nebraska. The fungus, which grows commonly as a saprophyte, was studied and attempts made to discover its means of being carried over from season to season. So far the author has been unable to find the organism on any portion of the apple tree except its fruit, but it has been reported as occurring on maple trees in a way that suggests it may possibly be parasitic. This point will be determined by subsequent investigations. The fungus has been found saprophytic on the black knots of cherry and plum trees, as well as on firewood, and also on the fruiting pedicels of grapes.

Inoculation experiments are reported in which the rot was easily produced, and preventive measures are suggested. Spraying the trees for the prevention of scab would greatly reduce the liability of attacks of rot, and the apples when gathered should be carefully assorted and placed in cold storage where a dry, low temperature would restrict the further development of the fungus. The effect of dipping apples in solutions of copper sulphate and of formalin was tested in which different strengths of solutions were used, and both the fungicides materially checked the growth of the fungus. A soft rot caused by *Penicillium glaucum* made its appearance upon the treated apples, being more abundant upon those than upon the check.

Apple troubles in 1902, F. H. HALL, F. C. STEWART, and H. J. EUSTACE (*New York State Sta. Buls.* 220 and 227, popular ed., pp. 8, pls. 4).—This is a popular edition of previous publications (see above and E. S. R., 14, p. 774).

Botanical investigations on fruit diseases (*Illinois Sta. Circ.* 67, pp. 15-19, fig. 1).—The botanical investigations reported were mostly made upon the bitter-rot fungus, preliminary accounts of which have already been given (E. S. R., 14, pp. 367, 581). Some other diseases were studied, among them the black rot, brown rot, apple canker, etc. Investigations were also conducted on the effect of spraying fruit trees while in bloom, the results obtained showing that spraying during the blossoming period prevents the setting of fruit in the case of those blossoms which have but recently opened. The fungicide seems to kill the stigmas and prevents the germination of the pollen.

Spraying for bitter rot (*Illinois Sta. Circ.* 67, pp. 10-15).—A brief report is given of the spraying which has been carried on by the station during 1901 and 1902 for the control of the bitter rot of apples. In 1902 the value of different times and numbers of applications was investigated, the work being carried on in 3 different orchards. The fungicide used was Bordeaux mixture composed of 4 lbs. of lime, 4 lbs. of copper sulphate, and 50 gals. of water.

In one orchard the trees sprayed were Ben Davis and Huntsman, the latter being extremely susceptible to bitter rot. A tabular statement shows that the Ben Davis trees sprayed 5 times before the appearance of the rot and once afterwards contained 3.93 per cent infected fruit, while those sprayed once shortly before the appearance of the disease and twice afterwards gave 16.84 per cent of fruit which was infected

with bitter rot, and the check trees which were not sprayed gave 44.94 per cent. The variety Huntsman, which is particularly susceptible to disease, was given a somewhat similar treatment. Trees sprayed 4 times before the appearance of the rot and twice afterwards yielded a crop 54.76 per cent of which was infected with the bitter rot. Trees sprayed twice after the rot appeared had 83.54 per cent of their fruit affected, while those not sprayed were attacked to the extent of 89.27 per cent.

In the other orchards the effect of treatment after the appearance of the disease was investigated. In one the trees of the Ben Davis variety sprayed 5 times after the disease had become fully established gave a crop 48.26 per cent of which was affected. Those which were sprayed 3 times after the disease was established were affected to the extent of 59.96 per cent, and the check trees 68.53 per cent. In the third orchard where Willow Twig trees were sprayed the percentage of infection was 57.82 per cent on trees sprayed 5 times after the disease appeared, 62.34 per cent on those sprayed 3 times after the appearance of the disease, and 63.81 per cent upon the nonsprayed trees.

From these experiments the conclusion is drawn that it is possible by the use of Bordeaux mixture to reduce the amount of bitter rot to less than 4 per cent in orchards where nearly 45 per cent of the fruit of unsprayed trees were affected. Applications should be made before the first appearance of the disease to be of the greatest value, although those made after the bitter rot had become established were not without some effect. The fruit should be well covered with the Bordeaux mixture and this can only be secured by several successive applications of the fungicide. The investigations for spraying are to be continued during the present year.

Apple canker, F. C. SEARS (*Nova Scotia School Hort. Rpt. 1901-2*, pp. 17-20, figs. 2).—A description is given of apple-tree canker, and results of treatment for its prevention are shown. Based upon his investigations the author recommends the cutting out of the cankers and painting over the exposed surface with copper sulphate followed by some heavy paint.

Report of the laboratory of vegetable physiology and fermentations, H. MÜLLER-THURGAU (*Jahresber. Vers. Stat. u. Schule, Wädenswil, 1899-1902*, pp. 66-94).—A report is given of investigations on frost injuries to fruit trees and grapes, the Monilia disease of stone fruit trees in which the twigs suffered severe injury, the browning or scorching of grape stock due to attacks of *Pseudopeziza tracheiphila*, testing wine ferments, on the fermentation of tannin-free pear must, and on the affections to which various wines are subject. Two papers by A. Osterwalder on the morphology of some species of *Saccharomyces* used in fermenting fruit wines and the formation of sulphureted hydrogen in fruit and grape wines are added.

Two diseases of vanilla, G. DELACROIX (*Reprint from Bul. Soc. Mycol. France, 18 (1902), No. 3, pp. 14, figs. 2*).—A description is given of 2 fungus diseases of vanilla, the first of which has previously been attributed to *Calospora vanillæ* and the second to *Uromyces joffrini*. According to the author, the fungus causing the first disease is a form of *Gloeosporium* or *Colletotrichum vanillæ*. It causes considerable injury to the vanilla plants, and for its prevention spraying with Bordeaux mixture or similar fungicide is recommended, care being taken to prevent the fungicide from coming in contact with the fruits. The second disease described produces a rust of vanilla and so far has not proved of any particular injury.

At the conclusion of this paper the author describes the development of *Gloeosporium musarum*, a fungus which causes a blackening of the banana fruit.

The gooseberry mildew in Europe, E. S. SALMON (*Jour. Roy. Hort. Soc. [London], 27 (1902), pt. 2-3, pp. 596-601, fig. 1*).—A review is given of the occurrence and distribution of the gooseberry mildew *Sphaerotheca mors-uvæ*. This disease seems to be widely spread throughout northern Europe and there is apparently evidence to show that the fungus is endemic in Russia and possibly elsewhere. Since the first report of the outbreak of this disease it has appeared in widely separated dis-

tricts and in every case assumed a serious character. A thorough spraying of the affected plants with potassium sulphid or Bordeaux mixture is recommended as a preventive treatment.

The distribution of the gooseberry mildew in Russia, P. HENNINGS (*Ztschr. Pflanzenkrank.*, 12 (1902), No. 5, pp. 278, 279).—The presence of the gooseberry mildew (*Sphaerotheca mors-uvæ*) in various parts of Russia is mentioned, and a number of new stations are added.

Chemical and physiological studies on the mulberry dwarf disease, U. SUZUKI (*Ztschr. Pflanzenkrank.*, 12 (1902), Nos. 4, pp. 203-226; 5, pp. 258-278, pls. 2).—This is essentially the same article as that previously noted from the bulletin of the College of Agriculture of the University of Tokyo (E. S. R., 13, pp. 61, 866).

Diseases of trees and plants, W. CARRUTHERS (*Jour. Roy. Agr. Soc. England*, 63 (1902), pp. 288-295, figs. 2).—Notes are given on the *Monilia* disease of plums, the apple scab, the cherry fungus (*Gnomonia erythrostoma*), clover disease caused by *Sclerotinia trifoliorum*, black mold of currants (*Capnodium salicinum*), and Rhizoctonia disease of mangel-wurzels. Attention is called to the diseased condition of potato tubers which is due to attacks of *Chrysophlyctis endobiotica*. Attention is also called to a previous publication in which it was claimed that this disease was due to *Ædomyces leproides*. The two fungi are said to be identical and the previous name is the proper one to be used.

Æcidium elatinum as the cause of witches' brooms of the silver fir, E. FISCHER (*Ztschr. Pflanzenkrank.*, 12 (1902), No. 4, pp. 193-202, pls. 2).—In continuation of his previous investigations (E. S. R., 14, p. 162) the author reports additional notes on *Æcidium elatinum* as the cause of the witches' broom of the silver fir. Numerous inoculation experiments are reported upon in which the acidio, uredo, and teleuto forms of the fungus were employed and the definite cause of the disease determined. The alternate generations of the fungus and their host plants are described.

The perithecial forms of *Phleospora ulmi* and *Gloeosporium nervisequum*, H. KLEBAK (*Ztschr. Pflanzenkrank.*, 12 (1902), No. 5, pp. 257, 258).—It is claimed that the perithecial form of *Phleospora ulmi*, a common fungus on elm leaves, occurs on the leaves that winter over attached to the tree or sometimes detached, and this form has been described as *Mycospharella ulmi*. The perithecial form of *Gloeosporium nervisequum*, the cause of the leaf blight of sycamores and other trees, is said to be *Lastadia veneta*.

A disease of lilacs caused by *Botrytis vulgaris*, C. J. J. VAN HALL (*Tijdschr. Plantenziekten*, 8 (1902), pp. 142, 143, pl. 1).—The author observed that the variety of lilac known as Madame Lemoine was affected by a disease caused by *Botrytis vulgaris*. No other variety of lilac was found similarly affected, although several nurseries were examined. The disease begins at the apex of the leaf and works back, drying up the leaf as it progresses. The dead portion of the leaf is marked with a series of rings, showing that the disease proceeds irregularly rather than steadily. The reason for the special susceptibility of this variety is thought to be its sensitiveness to wet weather, of which there had been a great deal during the season, and that therefore the plants were not in condition to resist the attacks of the parasite.—H. M. PIETERS.

Some pests of the flower garden, M. C. COOKE (*Jour. Roy. Hort. Soc. [London]*, 27 (1902), pt. 2-3, pp. 369-406, pls. 3, figs. 55).—Descriptive notes, together with suggestions for prevention, are given of a large number of diseases of many of the common plants in the flower garden. The diseases are popularly described, the distribution of the fungus indicated, and sufficient technical descriptions given for the specific identification of the different species of fungi.

A disease of the carnation, M. C. PORTER (*Jour. Roy. Hort. Soc. [London]*, 27 (1902), pt. 2-3, pp. 428-430, figs. 3).—A description is given of the leaf spot of carnations caused by *Septoria dianthi*. This disease has been under observation for

about 4 years, and the presence of the fungus in Great Britain has not hitherto been recorded. The fungus is described and the results of successful inoculation experiments are reported.

The treatment of fungus pests, A. HOWARD (*Imp. Dept. Agr. West Indies, Pamphlet No. 17, 1902, pp. 43, figs. 5*).—Brief popular descriptions are given of a number of the more common plant diseases known to occur within the West Indies, and suggestions made of measures to be adopted to prevent their spread.

Annual review of the literature relating to plant diseases, 1901, M. HOLLUNG (*Jahresbericht über die Neuerungen und Leistungen auf dem Gebiete der Pflanzenkrankheiten. Berlin, 1903, pp. VII+305*).—A review is given showing the progress that has been made in protecting useful plants against fungus, insect, and other depredations, and means for preventing loss from these agencies. The literature, which is quite voluminous, is for the most part grouped as in the previous reports (*E. S. R.*, 12, p. 658; 14, p. 62), the classification being essentially the same. In the present number the author gives a short summary of the present status of knowledge regarding the various topics discussed, followed by abstracts of the more important contributions relating to them and a list of related papers, some of which are briefly abstracted. The new grouping of all the references to a single topic will be found a decided advance over the former arrangement, in which the important abstracts were separated from the briefer ones and those which were only mentioned by title.

ENTOMOLOGY.

Proceedings of the fifteenth annual meeting of the Association of Economic Entomologists (*U. S. Dept. Agr., Division of Entomology Bul. 30, n. ser., pp. 124, pls. 2, figs. 6*).—An account of this meeting, held in Washington, D. C., December 26 and 27, 1902, has been previously given (*E. S. R.*, 14, pp. 535-538). In addition to the papers there noted, the following are included in the proceedings:

The lime-sulphur-salt mixture in Connecticut, W. E. Britton (p. 38).—This mixture proved to be as effective as any other remedy in the destruction of scale insects and did not injure trees in any case. It was also used in several large orchards with satisfactory results.

Development and hibernation of mosquitoes, H. A. Morgan and J. W. Dupree (pp. 88-92).—From these studies it is concluded that the 24 species of mosquitoes upon which notes were made can breed successfully in small pools. Most of the mosquitoes deposit their eggs singly upon the surface of the water. Water is believed not to be essential to the pupae of some species so long as moist soil is accessible. The only 2 stages in which the mosquitoes were found hibernating were the egg and adult conditions.

Some insect inhabitants of the stems of Elymus canadensis, F. M. Webster (pp. 92, 93).—This species was much more extensively infested by insects, especially those of the genus *Isosoma*, than other related species of the same genus.

Some insect notes of the year, F. M. Webster (pp. 93-96).—A brief discussion of the Hessian fly, apple aphid, *Scutellonotus zabriski*, *Ceratonia catalpa*, etc. It was observed that the red rust was more prevalent on wheat which had been attacked by the Hessian fly than on that which was not thus affected.

Mosquitocides, J. B. Smith (pp. 96-108).—Experiments were made to determine whether any insecticide substances could be mixed with water so as to prevent the development of mosquitoes. In these experiments the author tested permanganate of potash, Mosquitocide, salt, naphthaline, lime, copperas, crude petroleum, Phinotas oil, Phinotas disinfectant (5 per cent and 20 per cent), Phinotas Mark G, soluble blast furnace oil, Chloro-naphthalum, Puraline, Tarola, Milky Disinfectant, cretol, soluble creosote, Cresol (100 per cent), Phenol-septol, Synol Liquid, etc. These experiments indicate that there are several preparations which may serve as disinfect-

ants and larvicides, even when highly diluted. Good results were obtained from the use of Puraline and Phinotas oil.

Vernacular names of insects, E. W. Doran (pp. 108-111).—The author compiled a list of 3,500 compound vernacular names of insects and suggests certain rules to be observed in writing these compound words.

Notes on the larger sugar-beet leaf beetle, F. H. Chittenden (pp. 111-113).—*Monoxia puncticollis* was very injurious to sugar beets at Rocky Ford, Colo. Notes are given on the appearance, habits, and life history of this insect. For controlling the beetle the author recommends spraying with Paris green or arsenate of lead.

Some insects recently injurious to truck crops, F. H. Chittenden (pp. 113-120).—Biological and economic notes on the fall army worm, white grubs, leaf-footed plant bug, various species of blister beetle, *Scapteriscus didactylus*, *S. abbreviatus*, *Nysius minutus*, *Corizus hyalinus*, strawberry weevil, mealy bug on peanuts, *Elasmopalpus lignosellus*, etc.

Report of the entomologist, C. P. GILLETTE (Colorado Sta. Rpt. 1902, pp. 103-126, pls. 6).—During the season considerable loss was suffered from the attacks of grasshoppers, especially *Melanoplus differentialis*, *M. bivittatus*, and *M. femur-rubrum*. The author recommends plowing to destroy the eggs or the use of poisoned bran or hopper-dozers. About 400 tubes containing cultures of South African grasshopper fungus were distributed in various parts of the State and a few of the persons who used this fungus reported good results while a large number had no results. Experiments at the station with this fungus were an utter failure. No evidence was obtained to show that a single grasshopper had been killed by the fungus. In a few cases an investigation was made of localities where success had been reported and it was found that the grasshoppers were dying from another fungus (*Empusa grilli*).

Aspidiotus howardi is reported as injurious to pear and white-ash trees. Plant lice were unusually abundant, especially *Aphis pomi* and *A. riburni*. Sugar-beet leaf beetle (*Monoxia puncticollis*) destroyed about half of a 14-acre field of beets near Rocky Ford and also caused injury to beets at Ft. Collins. The beetles were found throughout the summer and the insect is double brooded. Paris green, London purple, and Paragrene gave good results when mixed with flour at the rate of 1:20. The native food of the insect consists of a number of plants which grow in alkali regions. The cherry slug was unusually abundant in the northern part of the State. Good results were obtained in combating this insect by spraying with Paris green, London purple, or Paragrene at the rate of 1 lb. to 160 gal. water, arsenate of lead at the rate of 1 lb. to 25 gal. water, white hellebore, 1 oz. to 3 gal. water, or by the use of pyrethrum or lime. Zenoleum used at the rate of 1 lb. to 50 gal. water killed the insects but injured the plants somewhat. Road dust was of little value.

Notes are given on the Western strawberry sawfly by S. A. Johnson. The species is described as new by A. D. MacGillivray, under the name *Empphytus gillettei*. The adult insect appears in May and early June and lays its eggs in the leaves. The larvae hatch in a few days and live for a week or longer on the lower epidermis of the leaf. At the end of 4 to 6 weeks they become full grown and crawl into the ground to pupate. There is 1 brood annually. White hellebore is recommended as a remedy.

Tychea brevicornis is reported as injuring beets. In preventing the attacks of this insect the author recommends that the beets should not be planted in ground that was previously occupied with corn or salt grass. Considerable injury is reported as having been suffered by pine trees in Platte Canyon. *Pinus ponderosa* was attacked by a number of bark beetles, including *Tomicus calligraphus*, *T. integer*, *T. oregoni*, *Dendroctonus ponderosa*, *D. valens*, etc. The author recommends cutting and burning dead trees and the cutting for timber or fuel of such trees as show signs of weakening.

A list of bee plants is given showing the more important flowering plants from

which bees gather honey in Colorado. Records kept showing the dates at which colonies of bees make their first gain in weight indicate that these dates correspond with the dates at which alfalfa begins to bloom. The dates varied from June 8 to 25.

Report of the State entomologist, A. L. QUAINANCE (*Rpt. Maryland State Hort. Soc.*, 5 (1902), pp. 22-27, fig. 1).—The author discusses the extent of orchard-inspection work done during the year and describes the method of procedure adopted in the case of infestation by San José scale. This insect was found in 1,280 localities in the State. The most satisfactory results in combating the San José scale were obtained from the use of lime-sulphur-salt wash applied just before the buds began to swell in the spring. For summer treatment the author recommends kerosene emulsion.

Principal injurious insects of the year, A. L. QUAINANCE and R. I. SMITH (*Rpt. Maryland State Hort. Soc.*, 5 (1902), pp. 39-110, figs. 11).—Biological and economic notes on the strawberry weevil, flea beetles, imbricated snout beetle, onion maggot, squash ladybird, pear-tree slug, rose chafer, *Melanophus bivittatus*, pea louse, and black peach aphid.

Report of the entomologist, C. FRENCH (*Jour. Dept. Agr. Victoria*, 1 (1902), No. 8, pp. 793-800, pl. 1).—Brief notes on the correspondence, publications, investigations, and experiments of the entomologist for the past season. Many additions have been made to the Museum of Economic Entomology and Ornithology and to the library. Notes are also given on the inspection of orchards, nurseries, and fruits, and a list is presented of the insects and fungi which are considered as dangerous under the Vegetation Diseases Act.

Annual report for 1902 of the zoologist, C. WARBURTON (*Jour. Roy. Agr. Soc. England*, 63 (1902), pp. 296-307, figs. 2).—The author discusses maggots in sheep, root-knot eelworm, oak tortrix, and black-currant gall mite. In preventing the attacks of the sheep botfly the author recommends the application to the sheep of some malodorous preparation, such as tar water. In the destruction of the root-knot eelworm considerable success was obtained from the use of carbolic acid applied at the rate of 33 oz. to 15 cu. ft. of soil. The use of remedies in the destruction of the black-currant gall mite was not attended with promising success. The author urges the desirability of securing uninfested plants at the start. Brief notes are also given on wireworms, *Eriophyes arellanae*, and *Oribata orbicularis*.

Orchard and bush fruit pests and how to combat them, C. WARBURTON (*Jour. Roy. Agr. Soc. England*, 63 (1902), pp. 115-134, figs. 12).—Formule are given for the preparation of Paris green, arsenate of lead, kerosene emulsion, and quassia mixtures. Among the injurious insects noted by the author special mention is made of winter moth, cherry sawfly, red spider, apple-blossom weevil, codling moth, apple sawfly, pear midge, woolly aphid, oyster-shell bark louse, leopard moth, currant sawfly, currant borer, currant gall mite, raspberry beetle, etc. Notes are given on the habits, life history, and approved methods of combating these species of injurious insects.

Entomology, M. V. SLINGERLAND (*Proc. West. New York Hort. Soc.* 1902, pp. 46-50, figs. 3).—Notes on the palmer worm, cankerworm, Hessian fly, striped cucumber beetle, cherry fruit fly, and fall webworm. The author discusses the value of lantern traps. It is believed that injurious insects may be combated much more cheaply and effectively by other means than by lantern traps.

Insects injurious to fruit trees, H. FAES (*Chron. Agr. Canton Vaud*, 15 (1902), No. 18, pp. 521-532, figs. 5).—Notes are given on the habits, life history, and means of combating codling moth, *Balaninus nucum*, *Cheimatobia brumata*, and other less important species injurious to fruit trees.

Observations and experiments in combating animal pests on fruit trees, grapevines, and garden vegetables, HOFER (*Jahresber. Vers. Stat. u. Schule, Wädenswil*, 1899-1902, pp. 108-121).—The author discusses the injurious habits of

Diplosis pyrrivora, *Cephus compressus*, *Lecanium vini*, and a number of species of gall mites. Experiments with mixtures containing soft soap showed that a 4 per cent solution was sufficient to kill the young lecanium. For destroying plant lice the author used a mixture containing soft soap, hard soap, and coal tar; also Nicotianin and mixtures containing soft soap and insect powder, and soft soap and quassia. A dilute tobacco decoction was also tested. All of these remedies proved very efficient in destroying the insects on the various fruit trees. In combating cabbage butterflies the author dusted flowers of sulphur, lime, and pulverized naphthaline on infested plants. Fluid sprays were used containing quassia, benzine, petroleum, tobacco extract, and a number of proprietary remedies. The dry insecticides had little effect, while quassia, benzine, and petroleum gave excellent results.

San José scale investigations, IV, V. H. Lowe and P. J. PARROTT (*New York State Sta. Bul.* 228, pp. 389-446, pls. 7).—The experiments reported in this bulletin were carried on in several localities in the State. No count of scales was made, since this method was considered inadequate as a check upon results. In laboratory experiments with infested apples, however, the scales were counted. As a rule the trees were sprayed once and then such portions as had been missed were later covered with the spray. A number of nozzles were used, the Seneca and Vermorel proving most satisfactory. An orchard of peach and plum trees on Long Island was sprayed March 25-29, the amount of mixture used averaging about $1\frac{1}{2}$ gal. per tree. The weather following the application was rather wet. The buds of the peach trees were delayed about a week in opening, but at the time of the final examination these trees were in better condition than the control trees. A slight injury appeared in the fruit buds of the plum trees, but this was not permanent. The scales were nearly all destroyed. The wet weather had little effect on the spray, the mixture remaining upon the tree until May.

Another orchard of plum and peach trees in Columbia County was treated March 31-April 1, with the same general results. There were severe rains for 30 days after the application, but the killing effects of the wash were apparently not diminished. An orchard of pear trees in Columbia County was sprayed April 1 and 2, the weather conditions being the same as those just mentioned. The results were likewise satisfactory, the scales being nearly all destroyed and the wash remaining on the tree for about 2 months. Similar results were obtained from the treatment of another pear orchard in Columbia County with but 1 application and no respraying. An apple orchard in Ontario County was sprayed April 23-26, when many of the buds had already opened. Rainy weather followed for a period of 30 days. The foliage appeared to be considerably injured, but the trees recovered from the burning. The average yield of apples in this orchard had been 80 bu., while after treatment the yield was 275 bu. The same satisfactory results were obtained from the treatment of apple trees in the station orchard. An orchard of pear and peach trees in Niagara County was treated April 7-16. Frequent heavy showers occurred during April and May. The leaf buds were somewhat burned, but no permanent injury was caused. The spray remained on the trees 2 months and the results were highly satisfactory. In these experiments 710 trees were treated, with uniformly good results in the destruction of the scales without serious injury to the trees and with evidence that rainy weather does not diminish the effectiveness of the wash.

In the laboratory experiments the principal object was to determine whether the insecticidal property of the wash is due to the soluble ingredients or precipitates in the wash. The mixture was sprayed on a glass plate, and after being allowed to dry was subjected to a water spray from an atomizer. The solution thus obtained was applied to infested apples. A large percentage of the insects were killed by this solution. Solutions obtained within 72 hours after the application of the wash to the plate were more efficient than those obtained later. An experiment to determine the length of time during which the wash retains its insecticidal properties showed

that the solution obtained from the first application to the dried wash killed all the scales, while that obtained 6 days later killed only 10 to 13 per cent.

In testing the effect of an excessive amount of precipitates upon the scale the author found that the precipitates exercised a pronounced mechanical effect, while soluble ingredients killed the scales immediately. The authors found by experiments that the solution due to a falling of rain upon the wash upon the trees destroyed scales which had not been touched by the first application. The effect of the precipitates in the wash without the soluble ingredients was most marked on the young scales, while the adults were but little affected. In these experiments 50 apples were used, the number of scales varying from 1 adult and 11 young to 63 adults and 1,250 young on each apple. In the test of lime-sulphur compounds as a summer treatment, peach and pear trees were sprayed on June 14. The leaves were nearly all killed, but new leaves formed and a good crop was produced. The scales were all destroyed. Similar results were obtained in experiments with plum trees. It was found possible to produce a lime-sulphur wash without boiling, by slaking lime, adding sulphur in the form of a dust to the lime while slaking, and then adding caustic soda to the mixture. This insecticide promises to prove satisfactory.

The authors experimented with a number of other washes, including resin wash according to the California formula and the station formula, lime-water-kerosene wash, ammonia-casein wash, lime-sulphur-salt wash and casein, lime-sulphur-salt wash using the liquid only, lime-sulphur-salt wash and Bordeaux mixture, and potash-sulphur wash. Of all these mixtures the lime-sulphur-salt and Bordeaux mixture gave the best results, and this is of practical importance on account of its combining both insecticidal and fungicidal properties. This mixture was obtained by making lime-sulphur-salt wash in the usual way, to which 1 lb. copper sulphate was added to 11 gal. of the mixture. The authors conclude as a result of their experiments that no special apparatus is required for the application of the lime-sulphur-salt wash, that the wash does not readily spread, and hence should be applied carefully, that the application should be made a short time before the buds begin to swell, and that this wash is a highly effective and safe treatment for trees infested with San José scale.

Spraying for the San José scale with the lime-sulphur-salt and other washes, F. H. HALL, V. H. LOWE, and P. J. PARROTT (*New York State Sta. Bul.* 228, *popular ed.*, pp. 8).—A popular summary of the above bulletin.

Orchard treatment for the San José scale, H. T. FERNALD (*Massachusetts Sta. Bul.* 86, pp. 15).—In the fall of 1901 the station orchard was found to be badly infested with San José scale. The orchard consisted of apple, pear, cherry, peach, plum, prune, and quince trees, numbering 612 in all. On the following March 27 treatment was begun and was continued until April 14. No injurious effects to the trees were produced by any of the different methods of treatment. The method of determining results consisted in inspecting the trees as soon as the first young larvae appeared, June 23, followed by a reinspection every week or two during the summer and fall. A potash-whale-oil soap, used at the rate of 2 lbs. to a gallon of water, freed only 28.12 per cent of the trees from the scale. Another potash-whale-oil soap gave better results, freeing 52.6 per cent from the scale. A whale-oil-tobacco soap was perfectly effective in 53.8 per cent of cases, while the following percentages of effectiveness were obtained by the other insecticides: Insect soap, 40.7 per cent; agricultural soap, 33½ per cent; crude petroleum in a 30 per cent mixture with water, 43.2 per cent; kerosene in a 36 per cent mixture with water, 44.4 per cent; lime-sulphur-salt wash, 65.6 per cent. The relative cost of materials per tree was as follows: Fumigation, 8 cts.; potash-whale-oil soap, 8 cts.; potash-whale-oil-tobacco soap, 9 cts.; agricultural soap, 4 cts.; crude petroleum, 4 cts.; kerosene, 4½ cts.; lime-sulphur-salt wash, 5 cts.; insect soap, 12 cts. A few badly infested trees were sprayed July 2 with 10 per cent kerosene, and good results were obtained. A major-

ity of the young scales were destroyed without injury to the trees. The author concludes from his experiments that the best method of treatment of orchard trees, where they are small, is by fumigation, while lime-sulphur-salt wash is the most satisfactory and effective spraying material.

San José scale, E. D. SANDERSON (*Delaware Sta. Bul. 58, pp. 16, pls. 4*).—This insect is described and notes are given on its origin, life history, means of distribution, and food plants. The remedies suggested by the author are cutting and pruning badly infested trees and treating other trees with kerosene emulsion, mechanical mixtures of kerosene or crude petroleum with water, whale-oil soap, and lime-sulphur-salt wash. Plum and pears treated with a mixture of crude petroleum containing 20 to 25 per cent of oil killed the scales without injuring the leaves. Fumigation with hydrocyanic gas is recommended as the most satisfactory treatment for small and medium sized trees.

Canadian experience in the use of lime, sulphur, and salt for San José scale, G. E. FISHER (*Proc. West. New York Hort. Soc. 1902, pp. 134-137, figs. 2*).—Brief notes are given on the use of crude petroleum, kerosene, and kerosene emulsion in the destruction of San José scale, together with an account of the use and value of the lime-sulphur-salt wash for this purpose. The latter remedy was found to be very satisfactory and is recommended as being perfectly effective and safe, even when applied by ordinary farm workmen.

Notes on lime-sulphur-salt wash as an insecticide, C. W. MALLY (*Ent. News, 13 (1902), No. 7, pp. 223-230*).—The author's experiments with this insecticide in combating *Diaspis pentagona* in Cape Colony is briefly related. Various formulæ were used, in which the amount of lime was varied and in some of which the sulphur and in others the salt and sulphur were omitted. From the author's experiments it is concluded that none of these formulæ is very efficient under South African conditions in the destruction of *D. pentagona* in the adult condition. The young larvæ are destroyed for a period of 3 months after the application. Frequent rains seem to have a favorable action upon the effectiveness of the insecticide.

Insect enemies of the apple tree and its fruit, L. BRUNER (*Trans. Amer. Apple Growers' Cong., 1902, pp. 100-106*).—Notes on the extent of insect injuries to apples throughout the country, together with a brief account of general remedies to be applied in controlling these insects and an analytical key for use in determining the various species.

Tent caterpillars, W. N. HUTT (*Utah State Farmers' Inst. Rpt. 1902, pp. 70-74, fig. 1*).—The tent caterpillar is reported as causing great injury to the terminal branches of fruit trees. Notes are given on the habits, life history, and remedies for this species.

A study of the parasites of the American tent caterpillar, W. F. FISKE (*New Hampshire Sta. Tech. Bul. 6, pp. 181-230, figs. 7*).—The author made continued observations on the parasites of the American tent caterpillar for a period of 4 years. It is estimated that the average number of caterpillars destroyed by parasites annually varies from 15 to 20 per cent. In 1900 it was 17.4 per cent. A table is given showing the comparative seasonal abundance of the 11 primary parasites of the tent caterpillar which were studied by the author. The primary parasites are as follows: *Pimpla conquisitor*, *P. inquisitor*, *P. pedalis*, *Limneria fugitiva*, a species of *Anomalon*, *Ameloctonus clisiocampæ*, *Cryptus extrematus*, *Rhogas intermedius*, *Bracom gelechias*, *Diglochis omnivorus*, and *Apanteles clisiocampæ*. The latter species and *Ameloctonus* are described as new. A number of the primary parasites serve in turn as hosts to secondary parasites, or sometimes become themselves secondary parasites. Notes are given on a number of the more important secondary and tertiary parasites.

Grapevine-root worm, E. P. FELT (*New York State Mus. Bul. 59, 1902, pp. 49-84, pls. 6*).—An outbreak of this insect occurred in Chautauqua Co., N. Y., in the neighborhood of Ripley, where about 80 acres of grapes were destroyed. The infested

area is described and notes are given on signs by which the presence of the insect may be known, and on the present conditions of infestation by this insect in the Ohio grape belt. The species is described in its different stages and notes are given on its life history. The number of eggs laid by female beetles varied between 106 and 184. The duration of the egg stage, as determined by the author, was from 9 to 12 days. Experiments were devised for the purpose of testing the burrowing power of the larvæ. A glass tube $\frac{1}{2}$ in. in diameter and 17 in. in length was bent so that 4 in. were vertical, and filled with loose earth. Grubs placed on the surface of the soil in the vertical part of the tube made their way down into the soil and through the whole length of the tube within a few days. One grub made its way through $7\frac{1}{2}$ in. of tightly packed soil within 6 days. It was found that the larvæ were able to exist for a considerable time without food. The insect feeds chiefly on grapes, but is also known to attack the Virginia creeper and occasionally other plants. A number of experiments were made in testing remedies for controlling this insect, and as a result of these experiments it is recommended that the soil be thoroughly stirred between the rows and near to the vines, so that the insects may be exposed in their pupal condition. The beetles may be collected by special catchers so constructed that they may be operated rapidly, and these remedies may be supplemented by thorough spraying, preferably with arsenate of lead. It appears that no one method can be entirely relied upon to control the insect. A brief bibliography of the species since 1866 is also given.

Some diseases of the potato and of fruit trees, A. LINTON (*Jour. Khediv. Agr. Soc. and School Agr.*, 4 (1902), No. 5, pp. 197-208, pls. 4).—Brief notes on the biology of insects, with a special account of the habits and life history of leopard moth, plum-stem borer, and a number of scale insects, together with a brief discussion of peach-leaf curl.

Sugar-cane borers—insecticides and fungicides, P. BONÂME (*Sta. Agron. Mauritius, Bul. No. 7, 1902, pp. 28*).—The common sugar-cane borer of Mauritius is not *Diatraea saccharalis*, but *Sesamia nonagrioides*. Notes are given on the habits and life history of this species, a translation of a note on the sugar-cane borer by H. Maxwell-Lefroy is presented, and a brief discussion is given of the formulæ and method of applying common insecticides and fungicides.

Cabbage-root maggots, G. H. CARPENTER (*Jour. Dept. Agr. and Tech. Instr. Ireland, 3 (1902), No. 1, pp. 109-113, pl. 1*).—Biological and economic notes on *Phorbia brassicæ*. The species is reported as having occurred in unusual numbers during the year 1901. In combating this insect it is recommended that close attention be given to the plants in order to determine the egg-laying period, and that eggs should be destroyed at once. A dressing of gas lime has been found useful in keeping off the flies. The use of tarred cards around the stem of young plants may be relied upon to some extent in preventing the deposition of the eggs. Brief notes are given on the natural enemies of this insect.

Australian ladybird beetles, W. W. FROGGATT (*Agr. Gaz. New South Wales, 13 (1902), No. 9, pp. 895-911, pl. 1*).—Notes are given on the habits and life history of a number of species of Coccidæ belonging to the genera *Epilachna*, *Coccinella*, *Callineda*, *Verania*, *Leis*, *Oreus*, *Novius*, *Rhizobius*, *Cryptodemus*, and *Scymnus*. A short bibliography of works relating to Australian Coccidæ is appended to the article.

The flea beetles—their life history, economical importance, and remedies against them, A. C. JENSEN (*Tidsskr. Landökon.*, 21 (1902), No. 6, pp. 379-393).

Screw worms in St. Lucia, St. G. GRAY (*British Med. Jour.*, 1903, No. 2204, pp. 724, 725).—Descriptive biological and economic notes are given on this insect. The author briefly discusses the distribution of this species and the nature of its attacks upon man and animals.

New Geometridæ and microlepidoptera from the European faunal region, A. FUCHS (*Stettin. Ent. Ztg.*, 63 (1902), No. 1, pp. 315-330).—Descriptive and eco-

onomic notes on *Crambus pascuellus*, *Tortrix corylana*, *Gelechia caminariella*, and related species.

Hymenoptera of Valais, E. FREY-GESSNER (*Bul. Murithienne, Soc. Valais. Sci. Nat.*, 1902, No. 31, pp. 21-80).—A monographic account of the genus *Haliectus*. A brief bibliography relating to this genus is compiled by the author and analytical keys are presented for the determination of the males and females belonging to the various species, some of which are described as new.

On the Hymenoptera collected by Mr. Robert Shelford at Sarawak, and on the Hymenoptera of the Sarawak Museum, P. CAMERON (*Jour. Straits Branch Roy. Asiatic Soc.*, 1902, No. 37, pp. 29-140).—Descriptive and biological notes on a large number of species of sawflies, Ichneumonidae, Mutillidae, and other families of Hymenoptera. Many of the species are described as new.

The wharf borer (*Nacerdes melanura*), T. BROWN (*New Zealand Dept. Agr. Rpt.* 1902, pp. 460-463, pl. 1).—This insect was found in large numbers in wooden blocks used for paving purposes. The upper surface of the blocks had been asphalted and were not injured to the same extent as the lower portions. The insect is described in its various stages.

Parasites of *Oiketicus platensis*, C. SCHROTTY (*An. Mus. Nac. Buenos Aires, 8* (1902), No. 1, pp. 45-48).—In addition to *Smicra bergi*, which was already known as a parasite of this insect, the author reports 2 other parasites, *Pimpla brasiliensis* and *P. tricolor*.

Metamorphoses of *Uroplata costipennis*, J. BRÉTHES (*An. Mus. Nac. Buenos Aires, 8* (1902), No. 1, pp. 13-17, figs. 9).—This insect lays its eggs on the under side of the leaves of *Sida rhombifolia*. Descriptive and biological notes are given on the insect in its various stages.

Contribution to a knowledge of the Rutelidæ, F. OHAUS (*Stettin. Ent. Ztg.*, 63 (1902), No. 1, pp. 1-57, figs. 10).—Notes are given on the habits and life history of a number of species of *Anomala* and related genera. Descriptions are given of all these species, some of which are new.

On some parasites of *Xylocopa tenuiscapa*, E. E. GREEN (*Ent. Mo. Mag.*, 2. ser., 8 (1902), No. 154, pp. 232, 233, fig. 1).—In trees tunneled by this insect the author found numerous specimens of *Cissites debeyi* in all stages. It is suggested that these beetles may be carried from one nest to another attached to the legs of their host. A parasitic mite (*Greenia parkinsi*) was also found associated with the bees.

Nursery inspection, C. M. WEED (*New Hampshire State Bd. Agr. Circs.* 1-3, 1903, folios).—The text is given of the recent New Hampshire law authorizing the State board of agriculture to appoint a State nursery inspector and to provide for the protection of trees and shrubs from injurious insects and diseases. The attention of the public, nurserymen, tree agents, and express and freight agents is called to the nature and provisions of this law.

The effects of drought upon insect life, MARY E. MURTFELDT (*Trans. Amer. Apple Growers' Cong.* 1902, pp. 119-121).—On account of the unusual drought in the Mississippi Valley in 1901 the hope was entertained that injurious insects would be unfavorably affected thereby. These expectations, however, were not realized, since the common noxious insects were present during the following season in as large numbers as usual.

Lantern trapping, E. J. SMITH (*Ent. News*, 13 (1902), No. 7, pp. 207-209).—A description is given of a lantern which is said to have proved very efficient in capturing moths for museum specimens. With regard to the economic value of the trap the author believes that the device is worse than useless, the number of injurious insects captured being very few.

Spray calendar (*Oregon Bd. Hort. Rpt.* 1902, pp. 70-90).—Formulae are given for the preparation of approved insecticides and fungicides, together with brief directions for the application of these remedies in combating common insect and fungus pests.

Insecticides and fungicides, A. B. CORDLEY (*Oregon Sta. Bul.* 75, pp. 21-43).—The nature of insecticides and fungicides is briefly discussed and notes are given on the methods of preparation and application of the better known substances of these classes. A brief list of plants is given in alphabetical order, with notes on some of the more important insect and fungus diseases to which they are subjected and recommendations regarding means of controlling these pests.

Paris green, W. C. STUBBS (*Louisiana Stas. Bul.* 73, 2. ser., pp. 174-176, 190, 191).—The results of examinations of 71 samples under the provision of the State law are reported.

Contribution to the knowledge of Anopheles, W. DÖNITZ (*Ztschr. Hyg. u. Infectiouskrank.*, 41 (1902), No. 1, pp. 15-88, pls. 2).—Detailed biological descriptive and economical notes are given on a number of species of *Anopheles* collected from various tropical localities.

The structure and biology of Anopheles maculipennis, G. H. F. NUTTALL and A. E. SHIPLEY (*Jour. Hyg. [Cambridge]*, 2 (1902), No. 1, pp. 58-84).—Notes on the resting position of the adult, the geographical distribution of the species, habitat, modes of dissemination, migration, hibernation, longevity, egg laying, number of generations, food, and influence of heat, cold, light, color, and sound upon the mosquitoes. A brief bibliography of related literature is appended to the article.

Characters of some mosquito larvæ, J. B. SMITH (*Ent. News*, 13 (1902), No. 10, pp. 299-303, pl. 1).—Extensive collections of mosquitoes were made for the purpose of studying the anatomy and habits of the larvæ. Notes are given on the characters and habits of the larvæ of a number of species.

Notes on the early stages of Culex canadensis, J. B. SMITH (*Ent. News*, 13 (1902), No. 9, pp. 267-273).—This species is said to be a common one in moist woodlands of New Jersey. Brief notes are given on the habits of the larvæ, which is said to prefer woodland springs and pools or ditches carrying spring water. The author never observed the larvæ in stagnant open water. A detailed description is given of the larvæ of this species.

Selecting the locality for an apiary, R. BEUHNE (*Jour. Dept. Agr. Victoria*, 1 (1902), No. 9, pp. 908, 909).—Attention is called to the effect of locality, and especially of the honey plants upon the color and other characters of the honey obtained. The author enumerates a number of plants which are valuable in the production of honey. Bee raisers are advised to locate their apiaries near red gum, yellow box, and gray box.

A scent-producing organ in the abdomen of the worker of Apis mellifica, F. W. L. SLADEN (*Ent. Mo. Mag.*, 2. ser., 8 (1902), No. 153, pp. 208-211, fig. 1).—In studying the phenomenon of humming in bees the author was led to investigate an abdominal organ in workers which was described by Nassanoff in 1883. It was found that this organ was capable of emitting a peculiar odor which may be of use to the bees in signaling to one another.

FOODS—NUTRITION.

Experiments on the metabolism of nitrogen in man, E. LANDERGREN (*Skand. Arch. Physiol.*, 14 (1903), No. 1-3, pp. 112-175, pl. 1).—Experiments with man are reported which were made with the special object of learning the minimum amount of protein required. In general the diet contained a limited amount of protein with an abundance of carbohydrates, or fat or both, to supply energy, while in one case the subjects fasted.

When a limited amount of protein was supplied under the experimental conditions the body reached after a few days a condition when apparently not more than 3 or 4 gm. of nitrogen was metabolized per day. Provided a minimum quantity of carbohydrates is present, the amount not being definitely known, the author regards it

probable that fat protects protein as well as an isodynamic quantity of carbohydrates, both in a condition of nitrogen hunger and nitrogen abundance. It was noted that under certain conditions fat exhibited less than one-half its protective power when carbohydrates were absent. This the author believes is explained by the fact that when carbohydrates are no longer supplied some must be formed in the body from protein, and that fat can not serve for this purpose in the place of protein. In other words, as soon as the glycogen is no longer present in the body fat is inferior to carbohydrates as a protector of protein.

This question and related topics, including the cleavage of protein during fasting, are discussed at length with special reference to the author's results and those obtained by other investigators.

Concerning the metabolism of phosphorus in adult man, R. EHRSTRÖM (*Skand. Arch. Physiol.*, 14 (1903), No. 1-3, pp. 82-111, figs. 2).—The author's experiments were made with 3 men, and the foods and excretory products were analyzed. The excretion of nitrogen and of phosphorus were not found to be parallel, the quantity of nitrogen being influenced by the protein content of the body and the quantity of phosphorus by the quantities of phosphates dissolved in body fluids, the amount in the skeleton, and also by the amount of lecithin and protein containing phosphorus.

The author concludes, therefore, that it is not necessary in metabolism experiments to calculate the ratio of nitrogen to phosphorus. As regards the metabolism of this element, the author notes that the amount of phosphorus present in food is one of the factors which affects the amount metabolized. The body has not the same tendency to accumulate phosphorus and reach a condition of equilibrium as is observed with nitrogen. Within limits at least, the metabolism of phosphorus is thought to be regulated in the same way as that of fat. That is, it can be stored up in the body or drawn upon, according to circumstances, for comparatively long periods. Further experiments on this point are regarded as essential. Apparently there is a minimum phosphorus requirement which varies within rather narrow limits, 1 to 2 gm. per day, supplied by an ordinary mixed diet, being, in the author's opinion, about the needed quantity.

The amount of phosphorus digested, the form in which it is best fitted for resorption in the body, the form in which phosphorus occurs in urine, the metabolism of nitrogen, and other topics are discussed.

The effect of different variables upon the excretion of carbon dioxid during positive muscular work, J. E. JOHANSSON and G. KORAEN (*Skand. Arch. Physiol.*, 14 (1903), No. 1-3, pp. 60-81, dgm. 1).—Continuing earlier work (E. S. R., 14, p. 992) experiments in which the respiratory quotient was determined are reported on the effects of training, duration of work, speed at which it is performed, and some similar factors upon positive muscular work, which consisted in raising and lowering a weight with the aid of apparatus of special construction. The authors conclude that in harmony with earlier observations the carbon dioxid excretion is directly proportional, within certain limits determined by practice or training, to the number of muscular contractions. It also appeared that with positive muscular work the carbon dioxid excretion was dependent upon the manner and duration of the muscular motion as well as the amount of external work produced. The effect of duration is greater in so far as it represents the duration of the muscular contractions in successive phases of motion. The experimental data are further discussed at some length.

The artificial method for determining the ease and rapidity of the digestion of meats, H. S. GRINDLEY and T. MOJONNIER (*Univ. Illinois, Univ. Studies*, 1 (1903), No. 5, pp. 8-20).—The results of a considerable number of digestion experiments with raw and cooked beef are reported and the experimental methods described. According to the authors the results indicate that there is a difference in the ease and rapidity

of digestion of the protein of raw meat and meat cooked by the common methods, the difference being most noticeable in the results of experiments in which the samples were digested with pepsin solution for 1 hour.

The data presented are not regarded as sufficient for final deductions, but, according to the authors, "it does seem that the protein of raw meat is more readily soluble or digestible than the protein of cooked meats. The experiments also indicate that the protein of meat cooked by boiling is more readily digestible than the protein of broiled or fried meats. The protein of fried meats is less rapidly soluble or digestible than broiled meat. These same differences are also noticeable in the results obtained after continuing the digestion for 2 hours, but after longer digestion these differences mostly disappear and after digesting with pepsin solution for 24 hours the digestibility of raw and cooked meats seems to be practically the same. Further, the results here reported show that the method of artificial digestion [as modified by the authors] gives a ready means of determining the relative ease and the rapidity of the digestion of the protein of foods."

In some of the experiments formalin was added after digestion had continued for a definite time and the material allowed to stand 24 hours before filtering. It is believed that the results indicate that formalin can be thus used for stopping the action of pepsin solution, but it is planned to investigate the subject further and test phenol and other substances also.

Calorimetric examinations of milk, A. SCHLOSSMANN (*Ztschr. Physiol. Chem.*, 37 (1903), No. 4, pp. 337-349).—The author reports determinations of the heat of combustion of a number of samples of human milk, as well as that of the cow, goat, and ass, and concludes that this value may be calculated accurately with the aid of factors.

The technique of calorimetric analytical methods, A. SCHLOSSMANN (*Ztschr. Physiol. Chem.*, 37 (1903), No. 4, pp. 324-336).—The method of determining heat of combustion with a Hempel bomb calorimeter is described and discussed.

Infant feeding (*Maine State Bd. Health Rpt. 1900-1901*, pp. 181-280, figs. 3).—Infant feeding, modified milk, and related topics are discussed, as well as the management of dairies in connection with the production of milk for the artificial feeding of infants.

The value of macaroni wheat for bread making, E. C. CHILCOTT (*South Dakota Sta. Bul.* 77, pp. 29-38, figs. 4).—The fact that macaroni wheats can be satisfactorily used for bread making is pointed out, and directions for its successful use and recipes by Alice D. Feuling are given. It is stated that the yeast fermentation proceeds more rapidly with macaroni wheat flour than with ordinary flour, that is, that the bread is raised more quickly.

The chemical and milling properties of macaroni wheat, J. H. SHEPARD (*South Dakota Sta. Bul.* 77, pp. 39-42).—A test made with a roller mill of a size suited for laboratory experimenting showed, according to the author, that macaroni wheat offered no special difficulties in milling, although the grains are "harder and require more power for their reduction than the ordinary bread wheats."

Modifying the milling processes slightly a sample of Kubanka macaroni wheat gave 6.38 per cent bran, 20.83 per cent shorts, and 71.54 per cent flour. The bran contained 16.3 per cent protein, the shorts 17.4 per cent, and the flour 16.9 per cent. The flour gave, according to the author, 54.8 per cent of wet gluten and 18 per cent dry gluten. "The difference between the wet and dry gluten shows the water-holding power of the macaroni flour to be all that could be desired." Data are also reported regarding the protein content of a number of samples of wheat which seem to show that the local-grown macaroni wheat contains more protein than the original seed.

Impurities in American wheat, A. L. WINTON (*Ztschr. Untersuch. Nahr. u. Genussm.*, 6 (1903), No. 10, pp. 432-447, figs. 16).—The principal weed seeds which

are found in wheat are described with special reference to their identification by microscopical methods.

Concerning the composition and digestibility of several sorts of Norwegian flat bread, S. TORUP and P. W. K. BÖCKMANN (*Arch. Math. og Naturvidensk.*, 24 (1901); *abs. in Centbl. Agr. Chem.*, 32 (1903), No. 4, pp. 235-240).—The digestibility of a kind of unfermented bread called "flat bread," made from oats and from barley, was studied in experiments with man, the income and outgo of nitrogen being also determined. The average digestibility of the oat bread with butter was: Dry matter 76.6 per cent, protein 63.7, fat 95, nitrogen-free extract 82.2, crude fiber 6.7, soluble ash 31.8, and insoluble ash 0.05 per cent. The average digestibility of the barley bread and butter was: Dry matter 86.1 per cent, protein 77.8, fat 95.3, nitrogen-free extract 91.3, crude fiber 6.6, soluble ash 51.5, and insoluble ash 0.3 per cent.

According to the authors, the Norwegian hard flat bread made without ferments is as well digested by healthy men as fermented bread. The crude fiber (from the hull) hinders markedly the digestibility of protein and carbohydrates. On the other hand, the digestibility of the fat of the butter eaten with the bread was little, if at all, affected. A considerable amount of the material ordinarily estimated as crude fiber was digested.

Aids to bread baking, O. VON CZADEK (*Ztschr. Landw. Versuchsw. Oesterr.*, 6 (1903), No. 2, pp. 195, 196).—Analyses are reported of commercial products which are said to increase the activity of yeast.

The baker's book, E. BRAUN (*New York: Author, Vol. I, pp. 306, pls. 9, figs. 99*).—This publication, which contains information of use to bakers and those interested in this trade, includes a number of descriptive, historical, and miscellaneous articles on bread and bread making, and other data, gathered from a variety of sources.

Chemical composition of cooked vegetable foods, KATHARINE I. WILLIAMS (*Proc. Chem. Soc. [London]*, 19 (1903), No. 262, p. 66).—The vegetable foods analyzed include raw and cooked broccoli, Brussels sprouts, dried peas, oatmeal, and macaroni.

Asphodelus tenuifolius, an Indian famine food, A. GHOSE (*Agr. Ledger*, 1902, No. 7 (*Veg. Prod. ser.*, No. 72), pp. 155-157).—The plants and seeds of *Asphodelus tenuifolius* are eaten in India in times of need. As shown by a chemical analysis, the seed contains fairly large amounts of protein, fat, and carbohydrates. Extracts from the seed were tested for alkaloids, but none was found. A test with iodine failed to indicate the presence of starch, nor was sugar detected. The seed contained about 25 per cent fat, the properties of which were studied to some extent.

The examination and utilization of horse-chestnuts, LAVES (*Oesterr. Chem. Ztg.*, 5 (1902), No. 22, pp. 511, 512).—In a paper presented before a meeting of the German Naturalists and Physicians attention is called to the food value of horse-chestnuts which have been treated with alcohol to remove the glucosid and bitter material present.

Concerning sulphured dried fruit, A. BEYTHIEN and P. BOHRISCH (*Ztschr. Untersuch. Nahr. u. Genussmitt.*, 6 (1903), No. 8, pp. 356-360).—Experimental data are reported regarding the occurrence of sulphurous acid in dried fruits, the subject being discussed from a hygienic standpoint.

Coffee substitutes (*Agr. News [Barbados]*, 2 (1903), No. 28, p. 148).—A brief note on the use of gumbo seed (*Abelmoschus*, or *Hibiscus, esculentus*) as a substitute for coffee.

Pineapple wine, A. SALLES (*Rev. Agr. [São Paulo]*, 8 (1902), No. 78, pp. 14-17).—The manufacture of wine from pineapples is described and discussed.

Pineapple wine, H. NEUVILLE (*Jour. Agr. Trop.*, 3 (1903), No. 21, pp. 70-72).—A critical discussion of the production of pineapple wine based on the article referred to above.

Food adulteration in Wyoming, E. E. SLOSSON (*Wyoming Sta. Bul.* 56, pp. 34).—

The text of the Wyoming pure food law is quoted, existing conditions discussed, and the results of a number of examinations, which were made in carrying out the provisions of the law, are reported.

Report on the examination of foods, drugs, and public water supplies, R. O. BROOKS (*Trenton: Edwin Fitzgeorge, 1903, pp. 30*).—The results of the examinations made at the chemical department of the New Jersey State Laboratory of Hygiene of samples of chocolate, cocoa, coffee, flavoring extracts, honey, milk, maple and other sirups, molasses, olive oil, spices and condiments, drugs, mineral waters, potable waters, etc., are reported. A number of samples of meat and meat products, butter, and grape juice were examined for added preservatives. None were found in the butter, grape juice, and mince-meat examined. Boric acid was found in 1 sample of sausage meat, 2 of Hamburger steak, and 1 of potted ham.

National association of State dairy and food departments (*Jour. Proc. Sixth Ann. Conv. Nat. Assoc. State Dairy and Food Depts., pp. 504*).—This volume includes the proceedings of the sixth annual convention of the National Association of the State Dairy and Food Departments held at Portland, Oreg., and a summary of the State pure food laws, court decisions, etc. The volume was compiled by H. B. Meyers.

The household food supply of the United Kingdom, R. E. TURNBULL (*Trans. Highland and Agr. Soc. Scotland, 5. ser., 15 (1903), pp. 197-211*).—A statistical article.

Relations of population and food products in the United States, J. H. BLODGETT (*U. S. Dept. Agr., Division of Statistics Bul. 24, pp. 86*).—A statistical article treating of the most important food products based largely, according to the author, upon the Census reports from 1850 to 1900. Some of the causes of the increase or decline observed in the production or use of different materials are discussed as well as other general matters.

The food factor in education (*British Med. Jour., 1903, No. 2205, pp. 797-800*).—A discussion of the character of the diet furnished in schools in England and the importance of adequate food for young and growing students. A number of examples of school diets are given.

Text-book of hygiene, M. RUBNER (*Lehrbuch der Hygiene. Leipzig and Vienna: Franz Deuticke, 1903, 7. ed., pp. XII + 982, figs. 295*).—In the new edition of this important work the author states that new material has been added, especially the results of investigations carried on since the last edition. The volume, which is designed for the use of students of medicine, physicians, sanitary officials, etc., contains chapters on food and condiments in addition to the other topics usually treated of under the general subject of hygiene.

ANIMAL PRODUCTION.

Variation in animals and plants, H. M. VERNON (*New York: Henry Holt & Co., 1903, pp. IX + 415, figs. 30*).—The 3 general subjects discussed in this volume are the facts of variation, the causes of variation, and the relation of variation to evolution. The following topics serve as titles to chapters under this threefold division of the book, viz.: Measurements of variation; dimorphism and discontinuous variation; correlated variations; blastogenic variations; laws of variation; effects of temperature, light, moisture, salinity, food, products of metabolism, and general conditions of life on variation; action of natural selection on variations; and adaptive variations.

The variation of animals is treated at greater length than that of plants. The author states that the keynote of much of the recent work on variation is the recognition of the fact that all problems in this field, in order to be studied effectively or be solved in a satisfactory manner, must be formulated in mathematical terms. It is no longer considered sufficient merely to state that a certain variation occurs to

a greater or less degree; it is necessary to state the exact amount of variation so far as it can be measured, and the proportion of cases in which it occurs, in order to make it possible to determine the degree of importance of any variation in the development of the species.

The author critically discusses the recent work of Bateson, de Vries, Poulton, Weldon, Vines, and many other writers, including the theory of variation proposed by Mendel.

Practical manual of animal feeding, R. DUMONT (*Manuel pratique de l'alimentation du bétail*. Paris: J. B. Baillière & Son, 1903, pp. 360).—This volume, which is one of the Bibliothèque des Connaissances Utiles, includes the general principles of animal feeding, feeding stuffs and their digestibility, and the practical feeding of farm animals, a number of tables of the composition of feeding stuffs, etc., being appended.

The inspection of feeding stuffs in 1902, F. W. MORSE (*New Hampshire Sta. Bul.* 98, pp. 15-23).—In carrying out the provisions of the State feeding stuff law, which is quoted, analyses were made of 57 samples of cotton-seed meal, linseed meal, gluten meals and feeds, hominy meal, commercial feeds, and cereal breakfast food by-products, poultry feeds, meat and bone meals, and calf meal. According to the author, the results of the analyses showed a satisfactory condition as regards quality, since "there are but few serious deficits in the goods as guaranteed."

Using vine prunings and grape marc with molasses for making molasses feeds, L. GRANDEAU (*Jour. Agr. Prat.*, n. ser., 5 (1903), No. 9, pp. 277, 278).—Data are quoted regarding the nutritive value of vine prunings and grape marc, which led to the deduction that such materials combined with molasses would make satisfactory feeding stuffs.

Industrial by-products used in the manufacture of molasses feeds, L. GRANDEAU (*Jour. Agr. Prat.*, n. ser., 5 (1903), No. 1, pp. 9-11).—This article is based on experiments reported by O. Kellner. (See below.)

Preparation and use of molasses bread for cattle feeding, G. MALET (*Bl. Zuckerrübenbau*, 9 (1902), No. 19, pp. 295-299).—Molasses bread for horses and for cows is described and the composition of the 2 sorts quoted. An experiment is also reported which, according to the author, shows that molasses bread to the amount of 3 kg. may form a part of the ration of horses. With cows it was found that molasses bread caused gains in weight but exercised no influence upon the quality or quantity of the milk. It is also stated that it facilitated and hastened the fattening of pigs.

The keeping qualities of certain peat-meal-molasses feeds, A. HERZFELD, O. SCHREFELD, and K. STIEPEL (*Ztschr. Ver. Deut. Zuckerind.*, 52 (1902), No. 554, p. 207; *abs. in Centbl. Agr. Chem.*, 32 (1903), No. 4, pp. 252-256).—Experimental data are reported and discussed.

Experiments on the digestibility of a number of materials used as absorbents in molasses feeds, O. KELLNER ET AL (*Deut. Landw. Presse*, 29 (1902), No. 103, p. 332; *abs. in Centbl. Agr. Chem.*, 32 (1903), No. 4, pp. 233-235).—In experiments with sheep the digestibility of mowrah meal, coffee hulls, peanut shells, and cocoa hulls was studied.

The protein of ground whale flesh, A. KAVLI (*Norsk Landmandsblad*, 21 (1902), pp. 281, 282; *abs. in Centbl. Agr. Chem.*, 32 (1903), No. 2, pp. 120-122).—The author has reported an extended study of the composition of the nitrogenous constituents of ground whale flesh, a concentrated feed extensively used in Norway, especially for milch cows.

The energy of growth and the lecithin in decoctions of cereals, M. SPRINGER (*L'énergie de croissance et les lécithines dans les décoctions de céréales*. Paris: Masson & Co., pp. 170).—The author believes that lecithin plays an important part in the growth of animals, and in this volume, which is one of the series *Encyclopédie Scientifique des Aide-Mémoire*, he has gathered together the results of numerous inves-

tigations which have a bearing upon this subject, the material being critically discussed. The lecithin in a decoction made from a mixture of cereals he regards as of importance in inducing growth.

Concerning the glucose and proteid material of a ration, L. DUCLERT (*Ann. École Nat. Agr. Montpellier, n. ser., 2 (1903), No. 3, pp. 212-223*).—Different amounts of glucose were fed to rabbits alone and in combination with alfalfa. The conclusion is drawn that unless the quantity eaten was excessive, glucose was thoroughly assimilated and did not exercise an effect upon the digestibility of protein.

The influence of hydroxile ions on tryptic digestion, A. KANITZ (*Ztschr. Physiol. Chem., 37 (1902), No. 1, pp. 75-80*).—Laboratory experiments are reported and discussed.

On the variations in the mineral, combined, and organized phosphorus in animal tissues, A. L. PERCIVAL (*Compt. Rend. Acad. Sci. Paris, 135 (1902), No. 22, pp. 1005-1007*).—Analyses are reported showing the relative proportions of mineral, combined, and organized phosphorus in a number of substances of animal origin. Some of the results follow:

Distribution of phosphorus in some animal products.

	Water.	Phosphorus (estimated as P_2O_5).			
		Total.	Mineral.	Combined.	Organic.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Muscles (beef).....	72.97	0.507	0.217	0.095	0.198

Kidney (mutton).....	79.11	.458	.232	.192	.030

The analytical methods are briefly described, and the results obtained are discussed.

Phosphates in the feeding of animals, A. GOUIN and P. ANDOUARD (*Les phosphates dans l'alimentation du bétail. Nantes: C. Mellinet, 1903, pp. 37*).—The principal material containing phosphoric acid which was used in the authors' experiments with calves was powdered green bone, which was fed with a basal ration of skim milk and starch, or skim milk, oats, and coarse fodder. In some cases phosphoric acid was also tested.

Judged by these experiments a calf a month old would tolerate 6.5 gm. of powdered bone per 10 kg. body weight and digest the phosphoric acid contained quite thoroughly. The phosphoric acid was well assimilated and the amount excreted in the urine was not less than 85 per cent of the amount assimilated. The amount of nitrogen and phosphoric acid in the food and excretory products is recorded in the 2 experiments reported, each of which extended over some 6 weeks.

The authors believe that in the form of powdered bone phosphoric acid exercises a very favorable effect on the nutrition of young ruminants, increasing the amount of nitrogen retained in the tissues and at the same time increasing the chemical changes in the body which result in the formation of body heat. In connection with the work the digestibility of oats was determined.

Cassava as a feed stuff, J. C. BRUNNICH and W. MAXWELL (*Queensland Agr. Jour., 12 (1903), No. 1, pp. 65-67*).—In connection with a study of the feeding value of cassava determinations are reported of the amount of hydrocyanic acid in young and old roots grown in Queensland. In view of the amount found the authors believe that farmers should be warned not to use cassava, in its natural state, as a human food or as a feeding stuff for animals.

Experiments on the possibility of removing the poisonous material by extraction with hot or cold water are briefly reported, which led to the following deduction: "While the cassava root in its natural state contains a highly dangerous amount of hydrocyanic acid, yet by treatment of the cut-up material with water, it can be rendered quite safe for food purposes. As a practical suggestion, it is advised that the cassava roots, if used at all, should be cut up into pieces and boiled in the same manner as potatoes are boiled for pig feed, the greatest care being taken that the water shall be completely removed, and the material further washed out with additional water. Concerning the actual amount of hydrocyanic acid found in cassava root by different scientists and in different countries, the indications are very strong that the controlling factors will be found to be the nature of the soil and climatic conditions."

Home produce v. purchased food, J. A. VOELCKER (*Jour. Roy. Agr. Soc. England*, 63 (1902), pp. 330-338).—Continuing earlier work (E. S. R., 8, p. 248) on the value of home-grown and purchased feeding stuffs, a test was made with 2 lots, each containing 8 cross-bred steers. After a preliminary feeding, each lot was fed 8 lbs. of grain per head daily in addition to 30 lbs. of roots, 4 lbs. hay, and 7.5 lbs. straw chaff, the amounts being increased as the test progressed. In the case of the home-grown products the grain ration consisted of beans, oats, and wheat, 7:5:4, and in the case of purchased feeds it consisted of linseed cake, decorticated cottonseed cake, and maize meal in the same proportions. All the feeding stuffs used were analyzed.

Four steers in each lot were fed in stalls, the others in yards, the former averaging 1,319 lbs. in weight at the beginning of the trial and the latter 1,449 lbs. The test covered from 84 to 106 days, the different groups being sold for slaughter at different times as they were ready. The steers fed home-grown products in stalls made an average daily gain per head of 1.5 lbs., and those fed the same products in yards 1.93 lbs. In the case of the purchased feed, the average daily gain with the steers fed in stalls was 1.98 lbs. and of those fed in yards 2.38 lbs.

Data are also reported regarding the cost of feed and live and dressed weight. The author calls attention to the fact that while smaller and more costly gains were made on the home-grown products the meat produced was considered superior.

[Gains made by steers on pasturage], Supplement to Bulletin No. 73, H. W. MUMFORD (*Illinois Sta. Circ.* 61, pp. 2).—The effect of previous feeding on subsequent gains made on pasturage was studied with 2 lots, each containing 25 yearling steers used in a test previously reported (E. S. R., 14, p. 381), on the comparative merits of corn silage and shock corn. In 175 days on blue grass pasturage the steers formerly fed the silage ration made an average daily gain of 1.03 lbs. per steer, and those formerly fed the shock corn an average gain of 1.2 lbs. Considering both of the tests the average daily gain of the silage lot was 1.249 lbs. and of the shock-corn lot 1.275 lbs.

"This does not indicate anything except that up to this time neither ration possessed a marked advantage for securing rapid gains on calves and yearlings up to the beginning of the finishing period. . . . The silage-fed steers have apparently larger frames, and largely on this account do not appear to carry as much flesh as the shock-corn-fed steers."

Feeds supplementary to corn for fattening steers, H. W. MUMFORD (*Illinois Sta. Bul.* 83, pp. 541-576).—The value of a corn ration supplemented by gluten meal and by clover hay was studied, the former feed being chosen because it is a corn product and its use is consequently of importance to corn growers, and the latter because it is believed that the possibilities of nitrogenous coarse fodders are not generally recognized.

Three lots of common to medium quality steers were selected, lot 1 being fed corn and clover hay, lot 2 corn, timothy hay, and corn stover, and lot 3 the same feeding

stuffs as lot 2 with gluten meal in addition. After a preliminary period of 3 weeks, the test proper began February 8, and covered 2 periods of 63 days each. During the first period unground corn was fed, and during the second corn-and-cob meal. At the beginning of the trial each lot contained 13 animals averaging 917 lbs. each in weight. As the trial progressed one was sold from each lot. The steers were fed in open yards, with sheds, at first coarse fodder ad libitum with 10 lbs. per head per day of grain, the amount being increased as the test progressed. At the conclusion of the trial the steers were slaughtered, the weight of the dressed carcass, organs, etc., being recorded.

The following table summarizes the results of the test as a whole:

Corn supplemented by other feeds for steers.

Feeding stuff	Nutri- tive ratio of the rations.	Average daily gain per steer.	Grain eaten per pound of gain.	Coarse fodder eaten per pound of gain.	Relation of live to dressed weight.
		<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Per cent.</i>
Lot 1, corn and clover hay	1: 9.43	2.51	7.68	4.82	58.9
Lot 2, corn, timothy hay, and corn stover	1:13.03	1.858	9.87	5.88	57.2
Lot 3, corn, gluten meal, timothy hay, and corn stover	1: 9.42	2.268	7.44	5.14	57.7

During the first period of the test 7 pigs, averaging 130 lbs. each in weight, followed each lot of steers, the number selected being just sufficient to utilize all the undigested grain and make satisfactory gains without additional feeding. During the second period each lot was followed by 4 pigs averaging 136 lbs. in weight. The smaller number was selected because the corn-and-cob meal furnished less undigested residue than the unground grain.

Considering the test as a whole the pigs following the 3 lots gained 542, 482, and 422 lbs., respectively. Taking into account both the beef and pork produced the author calculates that the average profit per steer in the 3 lots was \$13.16, \$4.45, and \$14.08. In his opinion the test emphasizes the importance of coarse fodder in steer feeding and indicates that clover hay may be advantageously used on account of the nitrogenous material it supplies, being especially valuable when a concentrated feed, such as gluten meal, is also used. Neither the ration of corn and nitrogenous coarse feed nor corn and nitrogenous concentrated feed was regarded as entirely satisfactory and it is believed "that some judicious combination of the two, yet to be determined, will be found more satisfactory and profitable than either.

"A ration of corn, timothy hay, and corn stover has little to recommend it for beef production. It is not favorable for the production of large, rapid, or economical gains; nor is the beef produced by the use of such a ration desirable. It requires 1.5 lbs. more grain and 0.7 lb. more roughage to produce each pound of gain where timothy hay supplemented corn than where clover hay was used.

"The corn and clover hay ration possessed the following advantages: [It is] available on Illinois farms; [it] produced large gains; considered either from the standpoint of total beef produced or the cost of such beef it was a large and economical producer; [and] the beneficial effects of the clover hay in the ration of lot 1 appeared to extend to the pigs, as not only were greater gains in live weight of pigs made in lot 1 than in the other lots, but also more economical gains."

In the author's opinion the slaughter test showed that a ration of corn and timothy had a tendency to produce a high percentage of internal fat without a relatively high percentage of dressed beef, thickness of flesh, or layer of surface fat, which are important items from a market standpoint.

"It is impossible to determine whether the corn and clover hay ration or the corn,

gluten meal, timothy hay, and corn stover ration had the greater tendency to produce lean beef, or flesh as greater gain of the steers fed corn and clover hay would naturally be followed by thicker flesh provided their lean beef making tendencies were the same. It is evident, however, that both the corn and clover hay rations and the corn, gluten meal, timothy hay, and corn stover ration had an advantage over the corn, timothy hay, and corn stover ration in this respect.

"It appears that the ration, where gluten meal is the conspicuous nitrogenous factor, has the ability to produce the finish demanded by the market with the least expenditure of both quantity and cost of food stuffs of any ration used in this experiment. The fact that there was more profit to the producer in the use of the ration containing gluten meal, notwithstanding the somewhat expensive nitrogenous concentrate used, is due to the combined facts of its being an equally effective ration as corn and clover hay to the securing of better finish without the necessity of putting on the maximum amount of unprofitable gains in live weight, and to the current prices of corn, gluten meal, and clover hay.

"The value of the manure made by the steers in lot 1 would be much more valuable per ton than that made by either of the other lots."

The author also calls attention to the fact that the condition of the feed lots is an important factor both as regards the extent and economy of the gains made. Thus, when the feed lots were dry and there was little variation in the weather gains were much more satisfactory than when the lots were muddy and the variations in temperature and humidity were great and sudden.

Live stock investigations, H. W. MUMFORD (*Illinois Sta. Circ. 65*, pp. 29, figs. 2).—The live stock investigations at the station are discussed and experiments previously noted (E. S. R., 14, pp. 381) and those reported above are summarized.

"**Cremaval**" as a supplement to skim milk in feeding calves, C. MOSER and J. KÄPPELI (*Ann. Agr. Suisse*, 3 (1902), No. 8, pp. 315-326, figs. 2).—As was the case with earlier tests^a Cremaval, a commercial substitute for natural milk fat, did not give favorable results with calves. In the investigation now reported whole milk had a feeding value of 2.91 cts. per liter, and the Cremaval ration 3.55 cts.

Sheep breeding, R. DOYLE (*Transvaal Agr. Jour.*, 1 (1902), No. 1, pp. 42, 43).—The subject is discussed with special reference to local conditions.

Economy of roots in sheep feeding, J. A. VOELCKER (*Jour. Roy. Agr. Soc. England*, 63 (1902), pp. 338-346).—Using 4 lots of 10 sheep each, the value of roots was studied. Lot 1 was given a full ration of roots and lot 2 a limited ration of roots, with linseed cake and clover hay in both cases. Lot 3 was also given a limited supply of roots and was fed linseed cake and chopped gorse in addition. Lot 4 received no roots, but was fed linseed cake and hay moistened with cane-sugar molasses mixed with water. The roots used were Swedish turnips and later kohlrabi. The test covered from 87 to 108 days, the different lots being sold as soon as they seemed ready for market. At the beginning of the trial the average weight of the sheep was practically 117 lbs. per head. The gain ranged from 26.5 lbs. with lot 4, receiving no roots, to 43.2 lbs. with lot 1, fed a full supply of roots. The feeding period was the longest with the former lot and shortest with the latter.

According to the author, "feeding sheep on a limited supply of roots will not fatten them as well or as quickly as giving them a more liberal supply of roots. Feeding sheep on the land without any roots, and making up for the deficiency by giving extra hay, with treacle and water, will result in considerable financial loss, and feeding with gorse in partial replacement of hay will give good mutton, but no economical advantage over hay."

Sugar beet as food for sheep (*Jour. Bd. Agr. [London]*, 9 (1902), No. 2, pp. 225, 226).—A test carried on at the Southeastern Agricultural College at Wye in 1900, with 2 lots of 12 sheep each and covering 12 weeks, showed that when they were

^a Ann. Agr. Suisse, 3 (1902), No. 3, pp. 59-70.

fed mangels in addition to a grain ration (corn, oats, and linseed cake) there was an average daily gain of 40.5 lbs. per sheep as compared with 33 lbs. when sugar beets were fed with the same grain ration. The sugar beets eaten were grown on 0.909 acre and the mangel-wurzels on an acre. The cost of growing the latter was less than the former.

The test was repeated in 1901 with 2 lots of 16 sheep each, fed respectively mangel-wurzels and sugar beets in addition to 1 lb. per head per day of oats, maize, and linseed cake. In the 8 weeks of the test the sheep fed mangel-wurzels made an average gain of 30 lbs. each, and those fed sugar beets of 22 lbs. "Moreover, the sheep which had received mangolds handled better, and their wool looked brighter than in the case of those receiving sugar beet. These results were, therefore, even more unfavorable to sugar beet than those obtained in the trials of the preceding year."

Angora goats in Australia (*Queensland Agr. Jour.*, 12 (1903), No. 2, pp. 113-116, pl. 1).—The possibilities of Angora goat raising under local conditions are discussed, as well as the importation of goats and goat management.

On the growth of suckling pigs fed on a diet of skimmed cow's milk, MARGARET B. WILSON (*Amer. Jour. Physiol.*, 8 (1902), No. 3, pp. 197-212).—In continuation of previous work by L. C. Sanford and G. Lusk, which is noted in detail, the author tested the comparative feeding value of skim milk with and without the addition of dextrose and lactose. Six new-born pigs of the same litter were obtained. Three were slaughtered and analyzed, and each of the rations tested was fed to one of the 3 remaining pigs. In the 16 days of the test the pig fed skim milk made a total gain of 883 gm.; that fed skim milk with 30 gm. of lactose hydrate per liter gained 1,140 gm., and the pig fed skim milk with the same amount of dextrose gained 986 gm. At the close of the test the pigs were slaughtered and analyzed. Below is the author's summary of this test and the earlier one referred to above:

"Skimmed cow's milk, with or without 2 to 3 per cent of added lactose or dextrose, is normally absorbed by suckling pigs. Two pigs fed on skim milk from 14 to 16 days gained 26.4 and 66.8 per cent in weight. Two pigs fed on the same skim milk, with 2 and 3 per cent of lactose added, gained 79.7 and 88 per cent in weight. Two pigs fed on the same skim milk, with 2 and 3 per cent dextrose added, gained 73.6 and 64.4 per cent in weight.

"Those fed with plain skim milk gained 114 and 218 gm. in weight for every 1,000 physiologically available calories in the food. The lactose pigs gained 222 and 215 gm. per 1,000 calories in the food. The dextrose pigs both gained 213 gm. per 1,000 calories in the food. Except in the case of one ill-nourished skim-milk pig, the growths of the sucklings stand in a constant ratio to the calories in the food.

"The pigs fed on plain skim milk used 23 and 35 per cent of the proteid in the food for tissue growth, the lactose pigs used 38 and 44 per cent, and the dextrose pigs 48 and 42 per cent. All the pigs of the second litter gained in fat when fed on plain skim milk or on skim milk with sugars.

"The percentage of calcium in the bodies of the pigs diminished with their growth. There was considerable and normal deposition of calcium in the pig, and this was proportional not to the calcium in the food, but to the growth of the animal. Not only is the growth in grams of the pigs proportional to the calories in the food, but the number of calories retained in the tissue substance during growth is proportional to the calories in the food. Eighteen to 19 per cent of the calories in the food were found stored in the tissue growth of the pigs fed on the 3 varieties of skimmed milk.

"There seems to be striking evidence that the suckling pig reared on skimmed cow's milk conforms to the same laws of nutrition as the breast-fed infant."

Measures for increasing pig raising, O. KNISPEL (*Arch. Deut. Landw. Gesell.*, 1903, No. 77, pp. 135).—The author describes the methods followed in different German States to encourage pig raising. He mentions the work undertaken by breeding societies, offering of prizes, vaccination of pigs, and related topics.

The management of swine, L. PRICE (*Queensland Agr. Jour.*, 12 (1903), No. 1, pp. 34-36).—On the basis of his own experience the author discusses the subject with reference to local conditions.

Molasses as a food for horses, G. H. BERNES (*Amer. Vet. Rev.*, 26 (1902), No. 7, pp. 615-623).—In addition to discussing some of the recent experiments on the value of molasses as a food for horses, the author reports several tests with a ration containing this material. Two horses weighing respectively 900 and 940 lbs. gained, in 6 weeks, 175 and 146 lbs., respectively, when fed 3 times a day 1 qt. of molasses (diluted with 3 qts. of water) mixed with 5 lbs. of cut hay. No long hay was fed in addition. They were given all the water they desired, but had no exercise. At the close of the test it is stated the animals were markedly improved in condition and "did their work well, in spite of the fact that they had not been exercised in 6 weeks."

A molasses ration was then fed for 14 months to 100 heavy truck horses, averaging 1,700 lbs. in weight, working 10 hours a day drawing very heavy loads, usually at a walk. They were fed per head morning and night 1 qt. of molasses diluted with 3 qts. of water, and thoroughly mixed with 6 lbs. of cut hay of good quality, 1.5 qts. corn meal, and 2.5 qts. of coarse bran, and in addition 5 qts. of dry oats in the middle of the day and 11 lbs. of long hay at night. It is stated that the animals gradually improved in condition and gained in weight, their coats becoming slick and glossy, while at the same time as much work was performed as before the test began. The general health of the horses was said to be excellent, cases of acute indigestion or spasmodic colic being rare, although formerly such attacks were of frequent occurrence.

Brief notes are also given regarding the successful feeding of a similar molasses ration to a number of other horses, of which 5 were driving horses. The author's summary follows:

"Molasses of a good quality is a most nutritious food for horses, easily digested and assimilated, and will in many cases correct faulty digestive processes. One quart of molasses at a cost of 3 cts. will take the place of from 3 to 4 qts. of good quality oats at a cost of from 4.5 to 6 cts.

"A sudden change from dry oats to molasses mixed with other food stuffs is perfectly safe and causes no disturbances of the digestive organs. Molasses-fed horses will do fully as much work and at the same time remain as a rule in much better general condition than animals fed on dry food, while the cost of feeding is reduced from 25 to 33 per cent."

Feeding experiments with horses: "Pail-mel" and maize, L. GRANDEAU (*Jour. Agr. Prat.*, n. ser., 5 (1903), No. 7, pp. 208-210).—A test with 3 horses is reported in which a molasses feed called "Pail-mel," which is a mixture of straw and molasses, was used. The amount of work done was measured by a dynamometer.

Nutritive value of "Pail-mel," a molasses feed, L. GRANDEAU (*Jour. Agr. Prat.*, n. ser., 5 (1903), No. 6, pp. 177-179).—The author reports the coefficients of digestibility of the rations fed when the horses were at rest, walking, and working. Data are also recorded regarding the amount of water consumed. The amount of molasses eaten varied from about 2.5 to 3.5 kg. per day. The animals all gained in weight, and the results as a whole are regarded as favorable to molasses feeding.

Handbook of horse raising, L. BORN and H. MÖLLER (*Handbuch der Pferdekunde*. Berlin: Paul Parey, 1902, pp. VIII+, 468, figs. 211).—This is the fifth revised edition of this volume, which is designed as a handbook for army officers and agriculturists. It treats especially of the anatomy and physiology of the horse, points, diseases, training, shoeing, and feeding.

Horse raising in the Rhine countries in the light of statistics, OLDENBURG (*Landw. Jahrb.*, 31 (1902), No. 5-6, pp. 791-821, maps 3).—Horse raising in relation to agriculture is discussed on the basis of statistical data.

Poultry division report, D. D. HYDE (*New Zealand Dept. Agr. Rpt. 1902*, pp. 127-134, pls. 4, figs. 2).—Brief statements are made regarding the poultry at the different New Zealand experiment stations. The export trade in poultry and eggs, especially with England and South Africa, is discussed at some length.

Profitable poultry farming, F. C. HARE (*Canada Dept. Agr. Comr's Branch, Poultry Division Bul. 6*, n. ser., 1902, pp. 47, figs. 37).—Poultry raising, dressing, marketing, poultry diseases, and other subjects relating to the poultry and egg trade are discussed.

Experiments in artificial incubation (*Queensland Agr. Jour.*, 12 (1903) No. 2, pp. 117, 118).—The tests reported show the need of moisture in the air of incubators and the desirability of adding it if removed too rapidly.

"The fatal effect of a rapid evaporation is to be found in the drying of the inclosing membrane of the eggs, or, in other words, the membrane covering the ovum becomes too dry to take up enough oxygen to suffice for the development and vital activity of the embryo, for while most animal membranes allow the exchange of carbon dioxide and oxygen to be effected with perfect ease, offering no serious impediment to the passage of either gas, dry membranes are impermeable to gases. Although the drying of the covering membranes often cuts short the development of the embryo, and the germs die at different stages of incubation, this most frequently takes place from the above cause from the seventeenth day to the end of the term, the greatest number dying about the eighteenth or nineteenth day."

The spoiling of hens' eggs preserved in wood ashes, H. SVOBODA (*Oesterr. Chem. Ztg.*, 5 (1902), No. 21, pp. 483, 484).—From experimental data the conclusion is drawn that wood ashes are not satisfactory for preserving eggs. It was found that when eggs were thus preserved the ash content was increased. An analysis of the ash of such eggs is reported.

The history of geese, J. J. McCUE (*Queensland Agr. Jour.*, 12 (1903), No. 1, pp. 40-41).—In this article, which is quoted from *Station, Farm, and Dairy*, the author describes the principal breeds of geese, including the black and white goose and the cereopsis goose, which are Australian varieties.

Ducks, G. ROGERON (*Les canards. Paris: J. B. Baillière & Son, 1903*, pp. VIII +, 435, pl. 1).—Different sorts of wild and domestic ducks are treated of, as well as the general subject of duck raising.

DAIRY FARMING—DAIRYING.

Feeding trials with cows, J. L. HILLS (*Vermont Sta. Rpt. 1902*, pp. 273-318 + XXXVIII).—This is the fifth year in which feeding experiments have been conducted along the same general line. Tests to compare low, medium, and heavy grain rations, to determine the feeding value of apple-pomace silage, and to ascertain the extent of experimental error in feeding trials made in previous years were repeated, and new trials were conducted to study the feeding value of malt sprouts, dried brewers' grains, and gluten meals of high and low protein content. The work is reported in detail and summarized, and an appendix contains the tabulated data. The trials covered a period of 24 weeks and included 50 cows. Each trial lasted 28 days, the conclusions in every case being based upon the results obtained during the last 18 days.

A comparison of 4, 8, and 12 lbs. of grain was made with 26 cows, with results essentially the same as previously obtained (E. S. R., 14, p. 78). An increase in the grain ration increased the yield of milk and butter, but not in proportion to the amount of grain fed. Changing from a low to a medium grain ration increased the yield of milk 9 to 13 per cent, and changing from a medium to a high grain ration did not increase the yield over 3 per cent. The quality of the milk was not materially affected. The dry matter in the low grain ration made proportionately more milk and butter than the dry matter in the medium ration, and the same was true when

the medium ration was compared with the heavy ration. The weights of about two-thirds of the cows increased or decreased as the amount of grain fed was increased or decreased. From a financial standpoint the results for 3 years were unfavorable to the high grain ration. For continuous dairy feeding the author favors a medium grain ration, 4 lbs. being considered lower than is advisable with cows of the better class.

Four cows were used in comparative tests of malt sprouts with (1) cotton-seed meal, linseed meal, and bran, and (2) oats and bran. As compared with mixture No. 1, malt sprouts decreased the yield of milk 10 per cent, but did not affect the quality of the milk nor the yield in relation to the amount of dry matter consumed. The use of malt sprouts was less economical. As compared with mixture No. 2, malt sprouts decreased the yield of milk 4 percent, the quality remaining unchanged. The dry matter consumed was 9 per cent less, making the yield in proportion to the dry matter 5 per cent greater than when oats were fed. The malt sprouts were not readily eaten by the cows in either experiment.

The relative feeding value of dried brewers' grains and a mixture of cotton-seed meal and linseed meal was tested with 1 cow. There was no marked difference in the yield and quality of milk. The use of brewers' grains was the more economical.

Gluten meals containing, respectively, 29.2 and 36.7 per cent of protein were compared with 4 cows, the results showing practically no difference as regards the yield and quality of milk and the amount of dry matter consumed.

A third trial of apple pomace was made with 12 cows. As much milk and 3 per cent more butter was produced on apple pomace as on corn silage. The yield per unit of dry matter was 7 per cent greater in the case of the pomace ration. No unfavorable effects were observed. A ton of apple pomace is considered as having practically the same feeding value as a ton of silage.

Additional data concerning the experimental error involved in feeding trials served to confirm the view already advanced that if 2 or 3 animals are used the experimental error inherent in the alternation method may be quite disregarded.

A comparison of feeding trial methods, J. L. HILLS (*Vermont Sta. Rpt. 1902, pp. 318-327*).—In earlier experiments (E. S. R., 14, p. 79) two methods of feeding were compared, one in which different rations were fed to the same group of animals during alternate periods, and one in which the animals were divided into 2 groups, one group being fed continuously on one ration and the other group alternately on different rations. While the results of the previous work seemed to show but little difference in the two methods, the present trials, made on a more extensive scale, favor the plain alternation system. The work is to be continued in the hope of arriving at more definite and satisfactory results.

Records of the station herd for 1900-1 and for 1901-2, J. L. HILLS (*Vermont Sta. Rpt. 1902, pp. 327-342*).—These records are similar in character to those previously reported (E. S. R., 13, p. 586). The average results for the 2 years are respectively as follows: Number of cows 47 and 49, yield of milk 5,814 and 5,166 lbs., fat content of milk 5.07 and 5.03 per cent, yield of butter 344 and 308 lbs., cost of food \$49.97 and \$49.13, and proceeds from sales of butter \$94.56 and \$85.33.

A comparison of score card judgments and of milk and butter records, J. L. HILLS (*Vermont Sta. Rpt. 1902, pp. 342-344*).—The station herd and 2 private herds were scored, the results being compared afterwards with the milk and butter records of the cows. The work was done by R. R. Strait, under the author's directions. In all 62 records were used in the comparison. The results seem to show that in the long run cows scoring high were but little if any superior as milk and butter producers. On the other hand, a relationship between lack of conformation to dairy types and lessened production was considered as plainly established.

The effect of feed on the quality of butter, J. L. HILLS (*Vermont Sta. Rpt. 1902, pp. 345, 346*).—In connection with the feeding experiments noted above and in con-

tinuation of previous work (E. S. R., 14, p. 79), 43 samples of butter, representing 191 churnings, were analyzed to determine the effect of different feeding stuffs upon the quality of the butter. As shown by analysis, apple pomace, corn silage, and dried brewers' grains had no effect upon the quality of the butter. Malt sprouts and ground oats, especially the latter, decreased the iodine number. Germ oil meal increased the iodine number. The gluten meals tended to produce soft butter. The content of volatile fatty acids was increased and the melting point and iodine numbers were reduced. As measured by inspection, the only bad effects on the quality of the butters were observed for a short period when malt sprouts were fed.

The change from barn to pasture, J. L. HILLS (*Vermont Sta. Rpt. 1902*, pp. 346-350).—Records of the station herd for 8 years as regards the yield and quality of milk for the 2 weeks preceding and the 6 weeks following a change from barn to pasture are discussed. During 4 years a majority of the cows showed a tendency toward immediate and decided improvement, followed by a return to the original quality. There was one year in the majority of cases a slow tendency toward improvement. During 3 years the quality of the milk of the majority of the cows remained practically unchanged. Reasons for the facts observed are not advanced. It is considered clearly established that no poorer milk results from pasture feeding even when the flow is considerably increased.

Dairy conditions and suggestions for their improvement, W. J. FRASER (*Illinois Sta. Bul. 84*, pp. 577-631, figs. 46).—The dairy conditions in the State have been under investigation by the station during the past 6 years. In some particulars the conditions are considered ideal, while in others they are far below the proper standard. This bulletin aims to suggest remedies for the faults most commonly found in actual practice. Some of the subjects discussed are the location and construction of barns and stables, care of yards, cleanliness in milking, care of milk and dairy utensils, feeding cows, construction and management of creameries, and markets for dairy products, numerous practical suggestions being made in each case.

Experiments to compare the amount of dirt falling from washed and unwashed udders during the process of milking are reported as follows: "It was determined after several trials with 3 different milkers on 30 cows that it requires an average of $4\frac{1}{2}$ minutes to milk a cow. A glazed dish 11 in. in diameter, the size of an ordinary milk pail, was placed in the top of a pail and held under a cow's udder in the same position as when milking. For $4\frac{1}{2}$ minutes the milker then went through motions similar to those made in milking, but without drawing any milk. The amount of dirt which fell into the dish during the operation was, of course, approximately the same as would have gone into the milk during the milking process. The dirt caught in the dish was then brushed into a small glass weighing tube, the udder washed, and the process repeated. The dirt which fell from the washed udder was also carefully brushed into a weighing tube. Both tubes were then placed in a desiccator, and after drying 24 hours were accurately weighed on a chemical balance. Sixty trials were made at different seasons of the year. With udders that were apparently clean it was found that an average of $3\frac{1}{2}$ times as much dirt fell from the unwashed udders as from the same udders after they were washed. With soiled udders the average was 22 and with muddy udders the average was 94 times as much dirt from the unwashed udders as from the same udders after washing."

Dairy investigations, W. J. FRASER (*Illinois Sta. Circ. 63*, pp. 7).—This is a report of progress on the dairy work which has been carried on by the station for nearly 2 years under State appropriations.

Variations in the composition of cows' milk, H. INGLE (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 15 (1903), pp. 135-182, figs. 12).—The author summarizes the results of his earlier investigations relating to the composition of milk (E. S. R., 14, p. 80) and reports further work, the main objects of which were to ascertain the effect of unequal intervals between milkings upon the composition of the milk, and

to discover a means of diminishing the difference in fat content between morning and evening milk when the intervals are unequal. Incidentally separate analyses were made of the milk yielded by each quarter of the cow's udder.

Five cows were milked at 6 a. m. and 3 p. m. during a period of 2 weeks. The average fat content of the morning milk was 2.87 per cent, and of the evening milk 4.26 per cent, the ratio between the two being 1:1.484. During the 4 weeks following the same cows were milked at 5.30 a. m. and 5 p. m. The fat content of the morning and evening milk was, respectively, 3.18 and 3.80 per cent, the ratio being 1:1.195. During a third period of 3 weeks with the hours of milking the same as in the first period the percentages of fat in the morning and evening milk were, respectively, 2.94 and 4.40, the ratio being 1:1.497. The results confirm the generally accepted conclusion that the low fat content of morning milk as compared with evening milk is due to unequal intervals between milkings. Following a change from unequal to approximately equal intervals the difference in percentages of fat gradually lessened.

The attempt was made to improve the quality of the morning milk by methods of feeding, the intervals between milkings remaining unequal. Cows on pasture were fed a grain mixture consisting of equal parts of cotton-seed meal and corn meal, one group receiving 3 lbs. morning and evening, one group 6 lbs. in the morning only, and one group 6 lbs. in the evening only. The different methods of feeding did not alter very much the relative yield of milk morning and evening. When the grain was fed only in the morning the fat content of the morning milk was increased, from which it would seem that where circumstances necessitate unequal intervals this plan of feeding would lessen the danger of the morning milk being below the standard.

The milk from each quarter of the udders of 2 cows was collected separately for 6 days and analyzed. The fat content showed no constant variations. In both cases, however, the milk from the left fore quarter was much smaller in quantity and lower in solids-not-fat than that from the other quarters. These results led to tests of the herd of 19 cows, the average results of which are given in the following table:

Yield and quality of milk from different quarters of the udder.

	Yield of milk.	Fat content.	Solids-not-fat.
	<i>Pounds.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Right fore quarter	2.42	3.86	8.78
Right hind quarter	2.47	3.96	8.68
Left fore quarter	1.85	3.84	8.45
Left hind quarter	2.50	3.85	8.71

"The variation in fat in milk from different quarters of the udder is perhaps not surprising when we remember that the fat is apparently produced by the breaking down of fat cells in the gland itself; but that different glands, or different parts of the same gland, should be able to elaborate, from the same blood supply, products of different concentration in dissolved matter, appears to the writer to be very remarkable. The results should certainly prove of interest to the physiologist, though they perhaps have little practical importance from a dairy point of view."

Ayrshire herd tests, F. W. MORSE (*New Hampshire Sta. Bul. 96, pp. 117-121*).—Tests of Ayrshire cows have been conducted by the station since 1894, some of the data being given in tabular form. The tests made during 1901 and 1902 show a range in the percentages of fat from 3.48 to 4.40, with an average of 3.88 per cent, and a range in the total solids from 11.71 to 13.27, with an average of 12.55 per cent. The author concludes that some of the herds are developing the quantity of milk at the expense of quality. Of 21 cows tested during the year, 15 gave the maximum fat test in the first month, and 13 the maximum yield of milk in the second month.

The milk supply of London, M. BEAU (*Jour. Agr. Prat.*, n. ser., 5 (1903), No. 17, pp. 535-537).—A brief general description of the milk supply of London.

Diminution of the content of lecithin in heated milk, BORDAS and RACKOWSKI (*Compt. Rend. Acad. Sci. Paris*, 136 (1903), No. 1, pp. 56, 57).—As compared with the quantity in raw milk, the percentage of lecithin was reduced 14 per cent by heating for 30 minutes at 60° C., 28 per cent by heating over a flame for 30 minutes at 95°, 12 per cent by heating over a water bath for 30 minutes at 95°, and 30 per cent by heating in an autoclave for 30 minutes at 105 to 110°.

The water content of creamery butter, H. E. ALVORD (*U. S. Dept. Agr., Bureau of Animal Industry Circ. 39*, pp. 4).—Previously noted from another source (*E. S. R.*, 14, p. 523).

The relation of carbon dioxid to proteolysis in the ripening of Cheddar cheese, L. L. VAN SLYKE and E. B. HART (*New York State Sta. Bul.* 231, pp. 21-41).—The investigations reported in this bulletin are summarized by the authors as follows:

"(1) The object of the work described in this bulletin was to ascertain the extent to which carbon dioxid is formed in American Cheddar cheese during long periods of time in the process of ripening, and also to learn the nature of the chemical changes that give rise to the production of this gas.

"(2) Two cheeses were used for this study. One was entirely normal; the other was made from milk containing chloroform and kept under antiseptic conditions. The investigation was continued 32 weeks, when a chemical study was made of the proteolytic end-products.

"(3) In the normal cheese, carbon dioxid was given off continuously, though in decreasing quantities after about 20 weeks, and had not ceased at the end of 32 weeks. The total amount thus produced was 15.099 gm., equal to 0.5 per cent of the fresh cheese. In the chloroformed cheese, the total amount of carbon dioxid produced was 0.205 gm., practically none being found after 3 weeks.

"(4) In the normal cheese, the following end-products of proteolysis were found: Tyrosin, oxyphenylethylamin, arginin in traces, histidin, lysin, guanidin, putrescin in traces, and ammonia. In the chloroformed cheese were found the same compounds, except oxyphenylethylamin, guanidin, putrescin, and ammonia; but arginin was found in marked quantities for the first time in cheese.

"(5) A consideration of the possible sources of carbon dioxid in the 2 cheeses indicates that in the case of the chloroformed cheese the carbon dioxid came from that present originally in the milk and that formed in the milk from the decomposition of milk-sugar before treatment with chloroform. In the case of the normal cheese, the carbon dioxid given off in its early age came largely from the decomposition of milk-sugar by lactic-acid organisms, while a small amount was probably due to the carbon dioxid present in the milk and to the respiration of living organisms present in the cheese. The carbon dioxid produced after the first few weeks came apparently from reactions taking place in some of the amido compounds, among which we were able to identify the change of tyrosin and arginin into derived products with simultaneous formation of carbon dioxid.

"(6) In the chloroformed cheese, the only active proteolytic agents were lactic acid, galactase, and rennet-pepsin. Under the conditions of our experiment, these agents were able to form neither ammonia nor secondary amido compounds with production of carbon dioxid. The presence of chloroform could not account for this lack of action. These results suggest that in the normal cheese there must have been some agent at work not present in the chloroformed cheese and that this extra factor was of a biological character."

Rusty spot and a remedy, F. H. HALL, H. A. HARDING, and G. A. SMITH (*New York State Sta. Bul.* 225, popular ed., pp. 7).—A popular summary of Bulletin 225 of the station (*E. S. R.*, 14, p. 908).

Report of the seventeenth annual meeting of the Granite State Dairy-men's Association, 1901 (*Granite State Dairy-men's Assoc. Rpt.*, 17 (1901), pp.

77).—This report includes the following addresses: Dairying in France, by H. E. Alvord; Creamery and Dairy Practice, by G. A. Smith; Some Points of the Dairy and its Adjuncts, by F. L. Davis; and New Hampshire Dairy Products at the Pan-American Exposition, by W. D. Baker.

Officials, associations, and educational institutions connected with the dairy interests of the United States for the year 1903 (*U. S. Dept. Agr., Bureau of Animal Industry Circ. 40, pp. 11*).

VETERINARY SCIENCE AND PRACTICE.

The first Norwegian veterinary meeting (*Maaanedsskr. Dyrlæger, 14 (1902), Nos. 6, pp. 253-303; 7, pp. 313-394; 8, pp. 403-469; 9, pp. 481-520*).—Among the large number of papers read at this meeting brief notes may be given on the following:

Combating bovine tuberculosis, J. Fibiger (pp. 253-255).—The author's experiments indicate that tubercle bacilli obtained from a young child were highly virulent for calves, and that therefore the disease as observed in man and animals can not be considered essentially different.

The work of combating bovine tuberculosis in Norway, Malm (pp. 259-274).—This work is said to have begun in 1891 and has since been prosecuted actively, with the aid of government appropriation. Tables are presented showing the number of localities in which infected herds are found, the breed of animals affected, and the percentages of tuberculous cattle as shown by tuberculin tests.

Combating tuberculosis in Sweden, G. Regnér (pp. 274-286).—Detailed notes are given on the temperature reactions in 250,321 cattle tested with tuberculin during the years 1897-1901, and other tables are given showing the percentages of infected animals in different herds.

The control of food materials with special regard to preservatives for meat, A. Jacobsen (pp. 313-346).—Notes are given on the etiology of cases of meat poisoning which have been found to be due largely to the presence in meat of *Bacillus coli communis*, *B. enteritidis*, *B. morificans bovis*, and *B. proteus vulgaris*. Special attention is given to the effect of various preservatives upon these bacteria and upon the keeping quality of meat, as well as upon the health of human beings.

Castration of Cryptorchids, F. Winter (pp. 358-388).—The literature of this subject is briefly reviewed and detailed descriptive notes are given on the various methods which have been devised and successfully used by various veterinary surgeons in performing this operation.

Results obtained by neurectomy, especially in cases of spavin, L. Morkeberg (pp. 403-433).—Detailed descriptions are given of a large number of cases in which neurectomy was performed for the cure or relief of spavin. In many cases double neurectomy is required, but according to the author's experience this method may be depended upon to bring about the desired results in about 70 per cent of cases.

Artificial insemination in mares, Sand (pp. 481-489).—The author believes that this operation may be resorted to with good results and may prove an important economic device under certain circumstances connected with the breeding of horses.

Aspergillosis in animals artificially fed upon milk, von Hellens (pp. 512-520).—A number of cases of this disease were observed by the author, especially in colts. The pathological anatomy of the disease sometimes gives rise to confusion with tuberculosis, and notes are given on the means of making a reliable differential diagnosis.

Report of chief veterinary inspector, J. G. RUTHERFORD (*Rpt. Min. Agr. Canada, 1902, pp. 71-152*).—This report includes, besides a general account of the health of animals by the chief inspector, a large number of reports of veterinary inspectors in

various parts of the Dominion of Canada. The majority of outbreaks of hog cholera reported were apparently due to the importation of hogs from infected parts of Ontario or from the United States. During the year 1,277 cattle were tested with tuberculin for export into the United States. Of this number 72 reacted. Very little testing of dairy cattle was done during the season. Experiments to determine the period which elapses between actual infection and the time when tuberculin produces a reaction indicate that this period varies from 8 to 50 days. It is recommended that so long as an animal does not show pronounced signs of generalized tuberculosis its progeny should be reared. A number of cases of glanders are reported. The author believes that a large percentage of glanderous horses ultimately recover without treatment. It is also suggested that horses which cease to react to mallein are no longer infectious.

Further studies were made on the Pictou cattle disease. This is a cirrhosis of the liver. Nothing definite has been learned regarding its cause. A report by W. H. Pethick contains a description of the conditions which actually prevail in the region where this disease is observed. It is stated that cattle raisers usually consider this disease as due to feeding upon ragwort (*Senecio jacobaeus*). Actinomycosis is said not to be so frequent as in former years. A few cases of anthrax were observed, but the infected area was closely quarantined and the ground subsequently burned over twice. Blackleg prevailed to considerable extent in the Northwest Territories and Manitoba. Verminous broncho-pneumonia appears to be on the increase among hogs in Ontario, especially where these animals are kept under unfavorable hygienic conditions. Brief notes are given on mange in cattle and horses, and on sheep scab.

Swamp fever in horses has prevailed in Red River Valley for a number of years, with very fatal results. This disease was investigated by the author and also by F. Torrance. The symptoms and the course and lesions of the disease are described in detail. It was shown that the disease is not surra. An organism was isolated which occurs more frequently than any other in cases of swamp fever, but inoculation experiments have thus far failed to demonstrate definitely its causal connection with the disease. A number of experiments were made on guinea pigs by C. H. Higgins to determine whether electric currents of high frequency exert any curative influence in cases of tuberculosis. The guinea pigs were inoculated with material obtained from a tuberculous steer. The treatment consisted in exposing the animals for 10 minutes daily to the effects of electric currents. After a few days' treatment the exposure was increased to 20 minutes per day. Detailed notes are given on the progress and duration of the disease in different animals. It was found as a result of these experiments that electric currents of high frequency exert a beneficial influence in assisting animals to overcome the action of tubercle bacilli. The average life of treated animals was 42.4 days, while that of untreated animals was 28.5.

Report of the city veterinarian, W. W. RICHARDS (*War Dept., Bureau of Insular Affairs, Philippine Com. Rpt. 1902, pt. 1, pp. 380-383*).—The author presents brief statistical notes on the numbers of domestic animals shipped into the Philippines from different countries. A brief discussion is also given on the diseases which have been observed among animals. The bladder worm was found quite extensively in hogs slaughtered at the public abattoir in Manila. Among 1,500 horses inspected 40 were found affected with glanders and all were killed. The public abattoir in Manila is under the supervision of a native inspector and from the notes kept concerning the numbers and conditions of animals slaughtered at this abattoir brief statistics are presented giving the number of condemned animals and causes of condemnation.

Work of the biological laboratory, D. C. WORCESTER (*War Dept., Bureau of Insular Affairs, Philippine Com. Rpt. 1902, pt. 1, pp. 293, 294*).—Brief notes on the work of this laboratory, which has been occupied largely in the preparation of sera for the detection and treatment of Asiatic cholera, surra, glanders, hog cholera, etc.

A large number of examinations were made of pathological tissue sent in from various localities. Considerable work has been done in the preparation of cultures of locust fungus to be distributed throughout the different provinces.

Bacterial diseases of animals, E. THIERRY (*Jour. Agr. Prat.*, n. ser., 5 (1902), No. 3, pp. 77-79).—Brief notes are given on the etiology of different classes of infectious diseases of animals.

Microbes and diseases of farm stock, J. DUNSTAN (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 15 (1903), pp. 1-32, pls. 8).—The objects of this article are to describe the essential features of bacteriology as applied to diseases, to draw attention to some of the most prevalent diseases of farm animals, and to indicate methods for dealing with them. Notes are presented on the biology of pathogenic micro-organisms, and on immunity, disinfection, anthrax, tuberculosis, glanders, blackleg, hog cholera, tetanus, pneumonia, strangles, contagious mammitis, contagious abortion, white scours, arthritis, actinomycosis, rabies, septicemia, ringworm, etc.

The nursing of veterinary patients, H. A. WOODRUFF (*Agr. Student's Gaz.*, n. ser., 11 (1902), No. 2, pp. 43-48).—Attention is called to the necessity of exercising special care in feeding and watering diseased animals in order to secure the best results from medicinal treatment.

Theories of immunity and their clinical application, A. S. GRUNBAUM (*British Med. Jour.*, 1903, Nos. 2203, pp. 653-655, fig. 1; 2204, pp. 715-720; 2205, pp. 783-786).—These were the 3 Goulstonian lectures delivered by the author at the Royal College of Physicians, London. The author discusses the theories of Metchnikoff and Ehrlich and shows that while they are apparently antagonistic, they are founded upon essentially the same phenomena and are different interpretations of the same functions. The following matters belonging to the general subject of immunity are discussed: Antitoxins, hemolysins, cytotoxins, incubation of diseases, effects of protective inoculation and infection on immunity, relapses and reinfections, predisposition, susceptibility, serum diagnosis, and partial agglutinins.

The antitoxic power of the organism and tissues toward certain poisons, G. ANGELICI (*Gior. R. Soc. Accad. Vet. Ital.*, 51 (1902), Nos. 46, pp. 1145-1151; 47, pp. 1169-1171; 48, pp. 1202-1205; 50, pp. 1271-1277; 51, pp. 1295-1299; 52, pp. 1314-1317; 52 (1903), No. 1, pp. 12, 13).—In the long series of experiments reported in this article the author tested the effect of certain poisonous substances, especially strychnin, upon the organism as a whole and upon the various tissues. Particular attention was given to the resisting power of the organism to poisons and to an investigation of the cause of this resistance. The experimental animals used by the author were chiefly guinea pigs and frogs, and the alkaloids with which most experiments were made were strychnin and nicotin. The alkaloids were injected hypodermically and intravenously. It was found that normal tissues may become somewhat edematous under the influence of strychnin when this is injected repeatedly. This alkaloid, however, spreads from the point of injection for considerable distances without undergoing any alteration. When fatal doses of strychnin are given in connection with olive oil in the form of an emulsion the poisonous effect of the strychnin is not produced. The same results were obtained from the use of phenol in frogs. The poisonous properties of calomel were similarly attenuated by mixing with olive oil. The author believes that the liver has the power of retaining and greatly altering alkaloids, especially strychnin, and this organ may be therefore considered as an important means of protecting the organism against the poisonous effects of strychnin. A brief bibliography of the subject is appended to the article.

Experimental study of inflammatory neomorphs in connective tissue, A. MAXIMOW (*Beitr. Path. Anat. u. Allg. Path.*, 32 (1902), Suppl. 5, pp. 262, pls. 13, fig. 1).—The author undertook an elaborate investigation of the processes which are concerned in the formation of neomorphic structures in connective tissue as a result of inflammation. The experimental animals were rabbits, dogs, and pigeons, and the

method of investigation consisted in the introduction of aseptic foreign bodies into the subcutaneous connective tissue. The histological processes which are observed in the formation of the new connective tissue are described in great detail. The elements which are most important in the formation of these new tissue are the polymorphous leucocytes, fibroblasts, and polyblasts. The fibroblasts are the ordinary connective tissue cells which existed before the inflammation set in. They begin to proliferate at a very early stage of the inflammation. The polyblasts are said to play an exceedingly important rôle in the formation of the new connective tissue. They are to be characterized as amoeboid wandering cells with a single nucleus.

General histological technique with special reference to the possibility of a morphological demonstration of cellular narcosis, H. ZANGGER (*Vrtljschr. Naturf. Gesell. Zurich*, 47 (1902), No. 1-2, pp. 42-72).—Detailed notes are given on the technique of staining animal cells by various methods with special reference to methods intended to demonstrate the presence of narcosis in various animal tissues.

Vasogen preparations in veterinary practice, A. HÖJER (*Deut. Tierärztl. Wchnschr.*, 10 (1902), Nos. 47, pp. 449-452; 48, pp. 455-457).—The vasogen preparations which have already been placed on the market by a firm in Hamburg number 20 or more. The author made experiments with a number of these preparations, especially in the treatment of suppurative wounds. Iodoform, iodine, pyocetanin, creolin, camphor, chloroform, creosote, and ichthyol vasogen were used, as well as mercuric vasogen salve and vasogenum purum spissum. In the author's experiments with these materials it was found that a rapid penetration and absorption took place, and the effectiveness of the preparations in inducing the process of healing was very striking. No irritation appeared to be produced by these substances upon the skin and no toxic effect was observed, whether used internally or externally.

Silver therapy, DORN (*Berlin. Thierärztl. Wchnschr.*, 1902, No. 27, pp. 403-405).—Notes are given on the use of colloidal silver in the treatment of puerperal septicemia, contagious coryza, and morbus maculosus, together with a brief account of the nature and therapeutic use of protargol and itrol.

The present status of photo-therapy and its application in veterinary practice, I. I. NEIMANN (*Arch. Vet. Nauk, St. Petersburg*, 32 (1902), No. 12, pp. 1017-1029).—A critical review of the literature of this subject is presented in connection with a bibliography. The author believes that light may be used under various conditions in the treatment of animal diseases, and suggests apparatus and arrangement of the same for convenient use in military veterinary hospitals and similar institutions.

Treatment of malignant edema with carbolic acid, with remarks upon "leeches," or bursattee, C. F. DAWSON (*Jour. Comp. Med. and Vet. Arch.*, 23 (1902), pp. 301, 302).—In an operation wound made for the purpose of removing a "leech" tumor, malignant edema developed. In treating the tumor for malignant edema, injections of strong carbolic acid were used, 1 dm. being injected daily for 3 days. The formation of gas within the tumor was checked and extensive suppuration occurred for some time, with recovery of the animal after 1 month.

Accidents following upon preventive inoculation and bacterial associations, V. GALTIER (*Jour. Méd. Vét. et Zootech.*, 5. ser., 6 (1902), Dec., pp. 697-703).—Brief notes are given on accidental infections which may be brought about during the performance of preventive inoculation. It is believed that the association of different bacteria may aggravate the effects of vaccination made with a benign virus so that more or less serious results may attend what would otherwise have been a harmless operation.

On the relationship of human tuberculosis to that of bovines, D. J. HAMILTON (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 15 (1903), pp. 232-278, figs. 3).—The author discusses the difficulties of determining the possibility of transmitting bovine tuberculosis to man, and also gives brief notes on the transmission of human

tuberculosis to cattle, the problem of the unity of tubercle bacilli, the relative virulence of this organism, the criterion of infection, and Arloing's criticism of Koch's experiments.

The author's experiments were arranged in 4 series for the purpose of testing 4 methods of transmitting human tuberculosis to cattle. In the first series the animals were fed on tuberculous sputum; in the second series calves were inoculated with material from caseous cervical glands of human origin; in the third series similar experiments were made, and also experiments in the subcutaneous inoculation of tuberculous sputum, intravenous inoculation of the same, and inhalation of tuberculous sputum; in the fourth series experiments were made for the purpose of determining whether human tubercle bacilli gain in virulence by being transferred from one bovine to another.

The general conclusions drawn from these numerous experiments may be summarized as follows: Human tubercle bacilli, although not so virulent for calves as the bovine form, may nevertheless be successfully inoculated in cattle. This statement is true whether the material is derived from lymphatic glands, tuberculous lungs, sputum, or urine. Positive results in infection are obtained whether the material is introduced by way of the mouth, by subcutaneous inoculation, intravenous inoculation, or by respiring a spray containing bacilli. The lymphatic system is always involved in these cases of experimental tuberculosis, and in general the organs most affected are those nearest the point of inoculation. Tubercle bacilli of human origin when transferred to calves gain greatly in virulence by this process. The author believes, therefore, that his results favor the view that the bovine and human tubercle bacillus are identical, although somewhat differently modified by the difference in environment.

Transmission of human tuberculosis to cattle, C. O. JENSEN (*Maanedsskr. Dyrtaeger*, 14 (1902), No. 9, pp. 527-534).—The author presents summary accounts of a number of experiments in which different authors have succeeded in transmitting human tuberculosis to cattle.

On the infectivity of the milk of tuberculous cows, the bacteriological diagnosis, and the practical value of tuberculin in the extirpation of tuberculosis among cattle, LYDIA RABINOWITSCH (*Jour. Comp. Path. and Ther.*, 15 (1902), No. 3, pp. 209-215).—This article is of a controversial nature and is largely occupied with a discussion of the importance of the milk from tuberculous cows as a factor in human tuberculosis. Since, in the experience of the author and many other investigators, tubercle bacilli are frequently found in the milk of tuberculous cows, it is urged that all means should be used for exterminating animals which may yield milk containing tubercle bacilli. This method includes the destruction of all animals suffering from mammary tuberculosis and a strict quarantine of animals in which a clinical diagnosis can be established only by the help of tuberculin. The time at which the latter class of animals should be killed will depend upon the rapidity of the course of tuberculosis.

Milk from tuberculous cows, J. M. YOUNG (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 15 (1903), pp. 212-216).—During the experiments reported by the author 17 among about 60 cows reacted to the tuberculin test. Among this number 4 were found to exhibit tuberculosis of the udder. From numerous inoculation experiments with the milk of these cows it was found that milk from cows affected with tuberculosis of other organs than the mammary glands possessed no virulence and was not capable of producing tuberculosis when inoculated into guinea pigs. The milk from cows suffering from mammary tuberculosis, however, was in all instances virulent and produced the disease in guinea pigs.

Should the use of the meat and milk of tuberculous animals as food be absolutely prohibited? L. DEL RIO (*Vet. Españ.*, 45 (1902), Nos. 1611, pp. 383-385;

1612, pp. 401-404; 1613, pp. 414-416; 1614, pp. 429-431; 1615, pp. 447-449; 1616, pp. 465-467; 1617, pp. 479-481; 1618, pp. 495, 496; 1619, pp. 512-514; 1620, pp. 528-530).—The author reviews the work of the various investigators along this subject. Attention is called to the importance of meat and milk as human food and to the possible dangers to human health from the consumption of tuberculous products. Brief notes are given on the classification of meat in abattoirs according to its hygienic condition. The author believes that, as a result of these studies and experiments, tuberculosis of man and cattle are 2 forms of the same disease. Brief notes are also given on the distribution and statistics of tuberculosis.

The Public Health (Scotland) Act, 1897, and its relation to owners of stock, J. HENDERSON (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 15 (1903), pp. 63-69).—Attention is called to the provisions of this law which relate to the sale of diseased animals and meat products. It is argued that in many instances the stock raiser may be unable to recognize the symptoms of disease and is not therefore criminally responsible for selling such animals for meat.

Cerebral tuberculosis, G. NUVOLETTI (*Gior. R. Soc. Accad. Vet. Ital.*, 51 (1902), No. 37, pp. 921-924).—The author describes the gross and microscopic features of tubercles obtained from the surface of the brain in cases of bovine tuberculosis.

Extracts of tubercle bacilli and other tuberculins other than those of Koch, L. GUINARD (*Rev. Tuberculose*, 9 (1902), No. 3, pp. 289-319).—The author gives a detailed description of the methods used in obtaining extracts of tubercle bacilli and producing tuberculin as practiced by Hunter, Cheyne, Klebs, Hirschfelder, Weyl, Denys, Vesely, de Schweinitz, Maragliano, von Behring, Arloing, Guinard, and Auclair.

Variations in the virulence of different cultures of tubercle bacilli, D. VENZPRÉMI (*Centbl. Bakt. u. Par.*, 1. Abt., 33 (1903), Nos. 3, Orig., pp. 176-184; 4, pp. 255-259).—The purpose of the investigations reported in the present paper was to determine whether there is in general a variation in the virulence of different cultures of tubercle bacilli corresponding to the differences in malignity of various cases of tuberculosis among human beings.

In these experiments 8 cultures were used from different human cases of tuberculosis; and from each culture material was taken for inoculation of 2 or more rabbits in the auricular vein. The amount of material used was about 3 mg. for each rabbit. Details are given concerning the effects of these different cultures on the experimental animals. It was found that tubercle bacilli in pure cultures when injected in suitable quantities into animal organisms may produce toxins which operate unfavorably upon experimental animals. These toxins are of considerable influence upon the severity of the infection. It was found also during these experiments that tubercle bacilli may indicate spontaneous degeneration and that artificial cases of tuberculosis may finally result in recovery. The tubercle bacilli in fresh cultures from different cases of human tuberculosis, especially of the pulmonary form, showed decided differences in virulence. Cultures of tubercle bacilli kept for a considerable period upon artificial nutrient media were gradually attenuated or completely lost their virulence.

It is believed as a result of these experiments that tubercle bacilli from different cases of this disease possess essentially different degrees of virulence, which may account in part for the observed differences in virulence and rapidity of extension in different cases of tuberculosis.

Treatment of parturient paresis with iodid of potash, L. MISIER (*Rec. Méd. Vét.*, 8. ser., 9 (1902), No. 11, pp. 342-345).—Excellent results were obtained from the use of hypodermic and intramammary injections with iodid of potash. After the administration of this chemical the author recommends the use of a hypodermic injection containing benzoate of eserine and sulphate of veratrin in water.

Treatment of parturient paresis, J. N. RUES (*Rec. Méd. Vét.*, 8. ser., 9 (1902), No. 15, pp. 479-480).—Brief notes on the successful treatment of this disease with iodid of potash.

Infusion or injection in parturient paresis, J. VLASKAMP (*Tijdschr. Veeartsenijk. Maandblad*, 29 (1902), No. 12, pp. 539-546).—The author believes that this disease is due to suppression of milk secretion and that the treatment of the disease should be directed toward restoring this physiological process. The injection of potassium iodid was found to have more rapid effect than infusion of the same substance. Infusion of lukewarm water and air had no apparent effect upon the disease.

Differential diagnosis between parturient paresis and apoplectic puerperal septicemia, E. H. B. GRAVENHORST (*Tijdschr. Veeartsenijk. Maandblad*, 30 (1902), No. 2, pp. 81-84).—Brief notes on the chief symptoms of these 2 diseases, which may be used in making a differential diagnosis.

Foot-and-mouth disease, J. G. RUTHERFORD (*Canada Dept. Agr. Bul.* 9, pp. 7).—The author presents brief notes on the history of foot-and-mouth disease in Canada and the United States, together with an account of the symptoms, treatment, and methods of preventing this disease.

The apoplectic form of foot-and-mouth disease, CHAPPELLIER (*Rec. Méd. Vét.*, 8. ser., 9 (1902), No. 16, pp. 453-468).—The author observed 19 cases of the apoplectic form of this disease. It was found that the animal might die suddenly while drinking and a variable quantity of liquid would be found in the trachea. In some cases the amount would be exceedingly slight. In other cases death resulted suddenly a short time after drinking. In these cases an autopsy showed that the trachea was filled with fluid. The author believes that these symptoms indicate a sudden development of an apoplectic condition in the brain. This supposition, however, is based on the symptoms only, and was not formed by an examination of the brain.

The latest recurrence of foot-and-mouth disease near Palermo, GRIGLIO (*Gior. R. Soc. Accad. Vet. Ital.*, 51 (1902), No. 30, pp. 753-756).—Brief notes are given on a recent outbreak of this disease, and also on the apparent immunity of Sicilian cattle to tuberculosis and on the successful treatment of rabies in a horse.

Baccelli's treatment of foot-and-mouth disease, A. CINTI-LUCIANI (*Gior. R. Soc. Accad. Vet. Ital.*, 51 (1902), No. 36, pp. 897-902).—The intravenous injection of solutions of corrosive sublimate, as recommended by Baccelli in the treatment of foot-and-mouth disease was tested by the author in a number of cases. These experiments indicate that the treatment is of considerable importance in the control of the disease.

Foot-and-mouth disease and the method of Baccelli, V. CANTONI (*Gior. R. Soc. Accad. Vet. Ital.*, 51 (1902), No. 41, pp. 1025-1029).—The author believes that Baccelli's remedy is perfectly reliable in the treatment of foot-and-mouth disease and that the discovery constitutes an important feature of the history of veterinary medicine.

Aspergillosis in cattle, A. QUARANTA (*Gior. R. Soc. Accad. Vet. Ital.*, 51 (1902), No. 34, pp. 849-860).—The author believes, as a result of a study of this disease, that aspergillosis may exist as a primary infection and that the disease may be readily differentiated from other similar diseases. In order to arrive at a thorough differential diagnosis it is recommended that the pulmonary tubercles be subjected to a microscopic examination.

Differential diagnosis of blackleg, K. D. MALINOVSKI (*Arch. Vet. Nauk, St. Petersburg*, 32 (1902), No. 12, pp. 1035-1038).—Statistics are presented showing the distribution and economic importance of this disease in Russia. Since blackleg is most frequently mistaken for anthrax, the author presents an outline of the chief clinical symptoms and pathological lesions of these 2 diseases for the purpose of making a differential diagnosis a simple matter for practicing veterinarians.

Rinderpest in South Africa, D. HUTCHESON (*Jour. Comp. Path. and Ther.*, 15

(1902), No. 4, pp. 300-324).—The author discusses the origin and spread of this disease in Africa. The disease apparently spread southward from a central focus. The symptoms and post-mortem appearances are described in detail and notes are given on the ordinary means by which the disease is spread. Preventive vaccination against rinderpest has been accomplished in two ways, viz: By the way of bile, and serum, and a careful description is given of both of these methods. The use of pure fresh bile from animals suffering with the disease or from animals which have just died is the method devised by Koch and has given excellent results in practice. Another method makes use of glycerinated bile, while equally good results have been obtained from the use of preventive blood serum. The author presents notes on the curative action of this serum and on the general method of procedure in eradicating rinderpest from the herd.

Texas fever among cattle in the Netherlands, D. A. DE JONG (*Tijdschr. Veeartsenijk. Maandblad*, 29 (1902), No. 12, pp. 531-538, pl. 1).—A microscopic examination was made of tissues of cattle which had died with symptoms of Texas fever. No ticks were found on the cattle, but the blood parasite of Texas fever was found in the tissues of affected animals, and it was therefore concluded that Texas fever exists in the Netherlands. The origin of the infection is not known.

Cases of pulmonary and pharyngeal actinomycosis in cattle, J. KOWALEWSKY (*Jour. Méd. Vét. et Zootech.*, 5. ser., 6 (1902), July, pp. 409-420, figs. 4).—A classified table is presented of 19,084 cases of actinomycosis, arranged according to the part of the body most or primarily affected. These statistics are supplemented by further cases obtained from other countries, with special reference to the occurrence of the disease in the lungs and pharynx.

Granulous contagious vaginitis in cows, P. BERGEON (*Jour. Méd. Vét. et Zootech.*, 5. ser., 6 (1902), Oct., pp. 598-601).—Brief notes on 3 cases of this disease, in one of which permanganate of potash was used, with recovery as the result in 14 days.

Experimental studies on barbone disease of buffaloes, BLIN and CAROUGEAU (*Rec. Méd. Vét.*, 8. ser., 9 (1902), No. 20, pp. 571-586).—According to the author's investigations of this disease it is an acute hemorrhagic septicemia due to a species of Pasteurella and common to nearly all of the countries of the extreme Orient. Notes are given on the morphology of the organism and on its behavior on various culture media. In inoculation experiments it was found that the organism was extremely virulent toward rabbits, guinea pigs, calves, adult cattle, buffaloes, dogs, and horses. Carnivorous animals were more resistant. It was found possible to immunize animals by the use of an attenuated virus. For the production of this virus the horse was found to be the most favorable animal. Notes are given on the technique of the preparation of an immunizing serum and on various methods of immunization. When small doses of virus, less than 1 cc., were inoculated simultaneously with 20 cc. of serum, a very persistent immunity was produced in cattle, calves, and buffaloes. When an injection of serum was given, followed by inoculation of virulent material, a refractory condition was likewise produced in the animal.

Barbone disease of buffalo in Indo-China, M. H. SCHIEN (*Rec. Méd. Vét.*, 8. ser., 9 (1902), No. 11, pp. 345-348).—The author states briefly the differences between this disease and true cattle plague. Formerly it was supposed that the buffaloes of Indo-China were dying of cattle plague; it was found, however, that the mortality among the buffaloes was very high, while cattle were not affected. The symptoms of the disease are briefly described. It was found that the disease could be experimentally transmitted to rabbits and calves.

The pseudo-cattle plague of Indo-China, CARRÉ (*Rec. Méd. Vét.*, 8. ser., 9 (1902), No. 16, pp. 467-472).—This disease, on account of its great mortality and rapid course, was for some time mistaken for true cattle plague. According to the author it is very probable that a number of contagious diseases exist among the cattle and buffaloes of Indo-China and that these diseases have not been sufficiently well studied to

permit a certain differentiation. The author found by experiment that the period of incubation of the pseudo-cattle plague was less than that of the true cattle plague, and that the diseases differed in other respects.

Bovine pasteurellosis in the Malay Peninsula, CAROUGEAU (*Rev. Méd. Vét.*, 8, ser., 9 (1902), No. 18, pp. 473-486).—As a result of the author's investigations it is concluded that the epizootic outbreaks in the Malay Peninsula are not due to cattle plague, but rather to hemorrhagic septicemia of cattle or bovine pasteurellosis. These outbreaks may appear under 3 forms—septicemic or peracute, acute with various localizations, and chronic. They are all due to the same organism, which belongs to the genus *Pasteurella*. This organism exhibits great variations in virulence. It was found possible to immunize animals by vaccinating them with an attenuated form of the organism. It is believed also that the data obtained from a study of the disease in the Malay Peninsula are applicable to outbreaks observed in Indo-China.

The bacillus of contagious abortion, H. PREISZ (*Centbl. Bakt. u. Par.*, 1. Abt., 33 (1903), No. 3, Orig., pp. 190-196, figs. 4).—The author proceeded along the lines of technique recommended by Bang in order to obtain pure cultures of this organism. The bacillus develops best in a medium consisting of agar with peptone and salt and containing a moderate amount of oxygen. The best development is obtained at a temperature of 37° C.; the optimum content of oxygen was found at a depth of from 7 to 15 mm. under the surface of the medium. The author describes in detail the behavior of this organism upon any artificial cultures. It is not stainable according to the Gram method. Experiments with female guinea pigs indicated that the organism does not cause abortion in these animals.

Abortion in cattle. Scours in new-born calves, L. VAN ES (*North Dakota Sta. Bul.* 54, pp. 151-167).—The author briefly discusses 3 forms of abortion, viz, that due to mechanical injury, the form due to eating moldy food, and infectious abortion. As causes of vegetable nature the author mentions ergot, corn smut, and certain evergreen plants. Infectious abortion attacks horses, sheep, and goats, but more commonly cattle. It is believed that cows affected with the disease gradually recover. The symptoms are described in considerable detail. No medicinal treatment is known which is successful in checking the disease. Attention should be given to preventive measures, such as destruction of the fetus and after-birth and the disinfection of animals, stables, and premises. Directions are given for carrying out disinfectant measures.

Scours in calves usually appears soon after birth and has been shown to be connected with a disease of the lungs which may appear somewhat later. There is little hope of success in treating this disease by drugs, but subnitrate of bismuth, creolin, or salol may often be used with encouraging results. Attention should be chiefly directed, however, to disinfection of stables and premises.

White scour and lung disease in calves, J. D. STEWART (*Agr. Gaz. New South Wales*, 14 (1903), No. 1, pp. 1-10, figs. 6).—This disease prevails in the older dairy regions of New South Wales to a considerable extent and causes a mortality which varies from 5 to 80 per cent. White scour and lung disease are associated as in other localities where the disease has been studied. Notes are given on the usual symptoms and complications as observed by the author. In preventing the disease it is recommended that care be exercised in introducing new stock, that new calf pens be constructed, that the posterior parts of the cow be washed, and that the umbilicus be ligatured and treated with carbolyzed oil immediately after birth. Infected calf pens may be freed of infection by antiseptic treatment and special attention should be given to the thorough cleansing of all receptacles which are used for holding milk to be fed to calves.

Ichthyosis in calves, S. ZERTZALOV (*Arch. Vet. Nauk, St. Petersburg*, 32 (1902), No. 12, pp. 1038, 1039).—Brief notes are given on the symptoms which this disease usually presents, as observed in calves. The same disease occurs in man, but usually under a somewhat different form.

Diseases in sheep, W. G. DOWLING (*Agr. Gaz. New South Wales*, 14 (1903), No. 1, pp. 15-17).—Strangury is reported as affecting as high as 20 per cent of rams and wethers in certain flocks of sheep. The disease appears to be contagious and it is suggested that flies may be instrumental in carrying the contagion. The treatment for severe cases is of a surgical nature and consists in the opening of the sheath and thorough treatment with antiseptic solutions.

Pasteurellosis and strongylosis of sheep, J. LIGNIÈRES (*Rec. Méd. Vét.*, 8. ser., 9 (1902), No. 22, pp. 669-679).—The author argues that pasteurellosis of sheep is due to the attack of a species of *Pasteurella* and that the disease may occur in a chronic form without the aid of an infestation by *Strongylus*. On the other hand the presence of these worms is favorable to the bacterial infection.

The vaccination of Algerian sheep against sheep pox, E. NOCARD (*Rev. Vet. Toulouse*, 27 (1902), No. 11, pp. 731-737).—A controversial article in which the action of the French Government in its attempts to check this disease is justified.

Swine erysipelas serum, L. DEUTSCH (*Centbl. Bakt. u. Par.*, 1. Abt., 33 (1903), No. 3, Orig., pp. 214-229).—In the author's experiments the serum for preventive inoculation against swine erysipelas was obtained from horses exclusively. The bacillus which was used in producing the serum was tested and found to be capable of producing death in pigeons when administered in doses of 1 cc. The virulence of the bacillus was increased by 12 passages through pigeons, so that finally 1 cc. of culture proved to be fatal to pigeons within from 36 to 42 hours. The author made a number of observations upon the agglutinating action of the serum. It was found that the agglutinating power is diminished by each injection of bacillus for 1 or 2 days, but gradually increases until from the eighth day on a more rapid increase in the agglutinating power takes place. When the agglutinating power of the serum unexpectedly undergoes a rapid diminution it is safe to conclude that the protective power has also become suddenly diminished. In testing the protective power of swine erysipelas serum the author considers it unsatisfactory to depend upon results obtained from the inoculation of mice. Pigeons should be used for this purpose, and the birds selected should be in good health and should weigh from 300 to 400 gm.

The control of swine erysipelas, A. VAN LEEUWEN (*Tijdschr. Veeartsenijk. Maandblad*, 29 (1902), No. 11, pp. 483-492).—A number of experiments were made in testing methods for the control of this disease. As the result of his investigations the author concludes that the virus of swine erysipelas is generally distributed throughout the Netherlands and that preventive vaccination, so far from being useful, is actually dangerous. The author believes that the disease may be communicated to healthy pigs by the use of the vaccine. Good disinfectants and veterinary police measures are recommended in controlling the disease.

Combating swine erysipelas, J. J. WESTER (*Tijdschr. Veeartsenijk. Maandblad*, 30 (1902), No. 2, pp. 49-63).—The author presents an elaborate discussion of the means of controlling this disease, with special regard to vaccination. Vaccination is said to be the most rapid method of diminishing the number of cases of swine erysipelas. It is also believed that the danger of communicating the disease by vaccination to live animals is exceedingly slight. The author urges the great value of preventive vaccination as the general measure of control. The Netherlands, however, are considered as being generally infected with the disease, and it is recognized that the bacilli of swine erysipelas are regularly found in hogs in that country.

Serum diagnosis in hog cholera and swine erysipelas, E. ERCOLANI (*Gior. R. Soc. Accad. Vet. Ital.*, 51 (1902), Nos. 27, pp. 690-693; 29, pp. 740-744).—The author studied the action of physical agents upon the agglutinating substances in blood serum of animals affected with hog cholera. It was found that serum maintained at a temperature of 50° C. for 2 successive days retained its agglutinating power without any change. When serum was suddenly subjected to low temperatures, its agglutinating power was stronger than when subjected for a number of days to higher temperature. As a result of the author's studies upon these subjects it is concluded

that the normal serum of experimental animals of the laboratory does not agglutinate the bacillus of hog cholera. Under the influence of a single subcutaneous injection of a culture of hog cholera bacillus the serum of hogs develops a slight agglutinating power. There is no relation between the agglutinating power of the blood serum of normal animals and the immunity or the natural susceptibility of these animals to hog cholera. There is also no connection between the agglutinating power of a serum of animals affected with hog cholera and its bactericidal power.

Prophylaxis of hog cholera, A. CINTI-LUCIANI (*Gior. R. Soc. Accad. Vet. Ital.*, 51 (1902), No. 35, pp. 873-877).—Attention is called to the great losses suffered among hogs as the result of this disease and to the desirability of securing some effective remedy which may be successfully employed on a large scale.

A method of vaccinating against hog cholera according to Poels, H. ANKER (*Tijdschr. Veeartsenijl. Maandblad*, 30 (1902), No. 2, pp. 63-80).—The details of various methods of vaccination against this disease are discussed and the method of Poels was thoroughly tested by the author. As a result of these experiments it was found that the use of Poels's method may cause the death of healthy pigs. Vaccinated pigs may suffer from a chronic form of the disease and may die after a period of weeks or months. They may also contract the disease in an acute form. It is urged, therefore, that great caution should be observed in the use of this method since healthy pigs from 9 to 11 weeks old were found to be unable to withstand the operation.

Infectious catarrhal pulmonary inflammation in hogs, L. GREVE (*Deut. Tierärztl. Wchnschr.*, 10 (1902), No. 52, pp. 491-493).—A number of outbreaks of this disease were observed by the author. The incubation period appears to be about 10 to 14 days, but may be as long as 24 days. In older hogs the disease assumes a mild form, but in young pigs, 6 to 10 weeks of age, the affection is of a more serious nature. The disease may be transmitted from one animal to another by association in the same pen. During the first few days of the disease the animals cough rarely, but later the cough becomes more frequent and more violent. After a period of several weeks the symptom of coughing gradually becomes less marked, but affected animals appear never to recover entirely from the cough. During the first stage of the disease the anterior lobes of the lungs are affected to a considerable extent. A post-mortem examination and bacteriological tests furnish criteria for making the differential diagnosis between this disease and swine plague or other diseases with which it might be confused. In treating the disease it was found necessary to isolate affected animals and to keep them in warm quarters with good ventilation. The author tried 2 experiments in the use of creosote preparations in treating this disease. Creosotal was found to check the coughing in a pronounced manner within a short time. According to the author, the disease is apparently becoming less severe in localities where it has persisted longest.

Third report on surra of cattle and horses in the Protectorate of Togo, SCHILLING (*Centbl. Bakt. u. Par.*, 1 Abt., 33 (1903), No. 3, Orig., pp. 184-189, fig. 1).—Observations were made on 7 horses affected with spontaneous cases of this disease, and it was found that *Trypanosoma* might be absent from the blood and organs, especially the bone marrow. Attempts to immunize horses by inoculation with blood parasites which had first been passed through dogs were without result. Similar negative results were obtained from the use of material which had been passed through both dogs and rats. The incubation period in cases of natural infection was found to be not longer than 9 days, while the course of the disease occupied from 43 days to 8 months. Two experiments were made on steers, during which blood parasites were used which had been subjected to 8 passages through both dogs and rats alternately. The previous treatment of these blood parasites did not prevent the development of acute diseases. A quite pronounced parasitic property, however, was developed in the blood serum, and it is believed that some results may be hoped for from experiments along this line. Further experiments of the same sort on cattle

and asses led the author to believe that the principle of immunization against African tsetse-fly disease has been found. In the process of immunization advantage was taken of the properties of the nagana parasites to become accustomed to the host, and in this way the virulence of the parasites toward a given species of animals was somewhat attenuated. A number of species of *Glossina* and *Stomoxys* were found, and brief notes are given upon these insects.

The American surra or mal de caderas, F. SIVORI and E. LECLER (*An. Min. Agr. Argentina, Zool. Bact. Vet. y Zool.*, 1 (1902), No. 1, pp. 79, pls. 51).—The disease which passes under the name of mal de caderas has been known in different parts of South America, especially Brazil and Argentine, for a number of years. It is believed to have appeared first in the island of Marajo at the mouth of the Amazon. The earliest report concerning its ravages was made in 1860, and a number of outbreaks occurred during that time and recent years. The most serious outbreaks, however, have taken place since 1897. The authors describe in detail the symptoms of the disease as seen in spontaneous cases. Perhaps the most pronounced symptom is that of progressive anemia accompanied with irregular gait and partial paralysis of the posterior parts. There is usually an increased sensitiveness in the loins. So far as the authors have been able to observe the disease is uniformly fatal. A number of autopsies were made and detailed notes are given on the results of these examinations. The *Trypanosoma*, which is the cause of this disease, is closely related to those which are already known to be pathogenic for domestic animals, but is believed to be distinct from related species. Some days it may be found in large numbers in the blood, and on other days it may be entirely absent. The cause of this great fluctuation is not well understood. Notes are given on the biology and morphology of this parasite. The blood organism is able to live in shed blood for at least 4 days. Agglomeration of the parasites was observed in preparations of the blood of badly infested horses, in the peritoneum of inoculated guinea pigs, and in the blood of infected cats. The organism may be transmitted artificially to horses, mules, and various other species of mammals. The progress of the disease is rapid in rats, mice, and monkeys, while it is considerably slower in horses, cats, guinea pigs, rabbits, and dogs. In goats the disease appears to assume a chronic form, while birds and batrachia proved to be refractory. The disease appears naturally in horses and mules. The blood parasite may be transmitted by a species of *Tabanus* not determined, by *Musca brava*, or by species of *Stomoxys*. Mal de caderas is considered by the authors as being closely related to nagana and almost or perhaps quite identical with Asiatic surra.

The development of nagana and its variations according to the species of animal, A. LAVERAN and F. MESNIL (*Rev. Vet. Toulouse*, 27 (1902), Nos. 9, pp. 569-580; 10, pp. 647-658; 11, pp. 714-728).—The author describes in detail the symptoms of nagana as observed in rats, mice, dogs, monkeys, rabbits, guinea pigs, horses, cattle, sheep, and goats.

Trypanosoma disease other than dourine in Algeria, M. BUFFARD and G. SCHNEIDER (*Rev. Méd. Vét.*, 8. ser., 9 (1902), No. 33, pp. 721-727).—In experiments which the authors undertook for the purpose of studying a supposed outbreak of dourine it was found that the organism with which they were working differed in its effects upon laboratory animals from that of dourine. The exact identity of the disease was not determined, but the possibility is suggested that the disease may prove to be surra.

Contribution to the serum diagnosis of glanders, M. A. RABIEAUX (*Jour. Méd. Vét. et Zootech.*, 5. ser., 6 (1902), Aug., pp. 463-471).—As a result of the author's investigations of this subject it is concluded that there is a marked difference between the agglutinating power of sera from glanderous and nonglanderous horses, and that this difference is sufficient to form a basis for the experimental diagnosis of glanders. Whenever the serum proves to be capable of producing agglutination when used in

a dilution of 1 to 1,000 the animal from which the serum was obtained must be considered as glanderous. This method is considered by the author to be quite technical, and it is not recommended as displacing other methods under all circumstances.

The use of antitetanic serum, A. LABAT (*Rev. Vet. Toulouse*, 27 (1902), No. 9, pp. 580-586).—The author's experiments in the use of antitetanic serum were made on horses which had received accidental or surgical wounds. Injections of this serum were made in 704 horses, 1 bull, and 1 ram. All the animals which were thus treated appeared to be protected against infection with tetanus; not a single case developed among the 706 animals. This treatment, while certain in its results, is but temporarily effective. The author believes that the immunization is not operative against the bacillus of tetanus, but merely against the toxin produced by the bacillus.

Enzootic bulbar paralysis in horses, M. H. J. P. THOMASSEN (*Tijdschr. Diergeneesk. Maandblad*, 29 (1902), No. 10, pp. 438-454, pl. 1, fig. 1).—A number of cases of bulbar paralysis were studied by the author. Notes are given on the distribution of the disease and experiments were made to determine its etiology. These studies were without definite results, since the author was unable to determine whether the disease was due to a bacterial organism or a vegetable toxin. The author believes, however, that the disease is due to a vegetable toxin which chiefly affects the medulla.

Pulmonary filariasis accompanying summer wounds, DROUX (*Rec. Méd. Vet.*, 8. ser., 9 (1902), No. 22, pp. 654-657).—The author describes cases of this sort in horses which had been condemned as affected with glanders. Numerous tubercles were found in the lungs, which proved to be due to infestation with *Filaria irritans*.

Filaria papillosa on the serous covering of the liver and pigment deposits on the serous covering of the intestines in horses, N. VUISOTSKI (*Arch. Vet. Nauk., St. Petersburg*, 32 (1902), No. 12, pp. 1046, 1047).—A number of cases of infestation of horses with this parasite were observed and notes are given on the apparent connection between the presence of the parasite and pigmented deposits on the external walls of the intestines.

Cases of epizootic lymphangitis in the form of chronic papular conjunctivitis in horses, I. G. USENKOV (*Arch. Vet. Nauk., St. Petersburg*, 32 (1902), No. 12, pp. 1039-1046).—The author presents notes on cases of this disease in horses, giving the clinical symptoms, pathological lesions, diagnosis, and treatment. In treating the disease the author recommends local anesthesia by means of cocaine, removal of the papules, and treatment of the affected surfaces with antiseptics, such as carbolic acid.

Parasitic dermatitis, CADÉAC (*Jour. Méd. Vet. et Zootech.*, 5. ser., 6 (1902), Sept., pp. 520-522).—Brief notes on a skin disease of horses, due to *Dermophilus irritans*.

Contribution to the study of botryomycosis, V. LAFARGUE (*Rev. Vet. Toulouse*, 27 (1902), No. 12, pp. 772-784).—Notes are given on the etiology, symptoms, and various forms of this disease, which occurs in horses and other animals as well as man, and is due to *Botryomyces equi*. A detailed description is given of the symptoms and pathological anatomy observed in the acute skin form of the disease.

The sting of *Bombus terrestris* and the serious symptoms which it produces in horses, R. BISSAUGE (*Rec. Méd. Vet.*, 8. ser., 9 (1902), No. 11, pp. 337-341).—In cases where the sting of this insect caused serious symptoms the author obtained good results from the use of subcutaneous injections of sulphate of veratrin. It is argued that the more severe symptoms can not be due entirely to the action of formic acid but that some other substance must be present in the virus of the bees.

The pathological importance of botfly larvae in the stomach of a horse, E. PERRONCITO (*Gior. Soc. R. Accad. Vet. Ital.* 51 (1902), No. 32, pp. 801-805).—Descriptions are given of a few cases in which botflies caused the death of horses as a result of lesions produced in the stomach.

Flatworms parasitic in domesticated animals, R. S. McDougall (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 15 (1903), pp. 279-311, figs. 12).—Notes on the habits, life history, and means of combating *Distomum hepaticum*, *D. lanceolatum*, *D. macrostomum*, *Tenia saginata*, *T. marginata*, *T. solium*, *T. serrata*, *T. echinococcus*, *T. crassicolis*, *Moniezia expansa*, *Bohricephalus latus*, etc.

Poisonous properties of certain species of Equisetum, C. E. J. LOHMANN (*Jour. Landw.*, 50 (1902), No. 14, pp. 397-404).—Feeding experiments were conducted with a number of species of *Equisetum*, and the results are given in detail in the present paper. Parts of the fruiting specimens of *Equisetum arvense* were fed to rabbits without producing any poisonous effects. Sterile sprouts were also fed to rabbits with negative results. *E. palustre* when fed to rabbits produced peculiar spasms and resulted in death in some cases. This species is believed to contain a nerve or muscle poison. *E. sylvaticum* was also found to be somewhat poisonous although less so than *E. palustre*. *E. maximum*, *E. pratense*, and *E. limosum* were fed to animals with negative results. Filtered extracts from *E. sylvaticum*, *E. arvense*, *E. limosum*, *E. pratense*, and *E. maximum* were injected into rabbits, with negative results. The explanation of these results is not understood by the author. It is believed, however, that the poisonous principles of the different species are not identical.

Potassium permanganate in the treatment of ulcerous keratitis, B. DANOU (*Rev. Vet. Toulouse*, 27 (1902), No. 10, pp. 646, 647).—Experiments were made in the treatment of 4 dogs for this disease. A solution of potassium permanganate was used in the proportion of 1 part to 2,000 of tepid water. Excellent results were obtained in all cases.

Preventive treatment for rabies in horses by means of intravenous injections of rabies virus, A. CONTE (*Rev. Vet. Toulouse*, 27 (1902), No. 7, pp. 434-442).—The author treated 5 horses which had been bitten by mad dogs. The treatment consisted of intravenous injections of material obtained from the medulla of rabid dogs. In these experiments 5 cc. of an emulsion of the virus was injected into the jugular vein in each animal. Four of the animals died ultimately with pronounced symptoms of rabies. The treatment began within from 3 to 6 days after the animals were bitten. It appears, therefore, that this treatment is of little value in preventing the appearance of rabies in horses.

The histological diagnosis of rabies in dogs, A. RABIEAUX (*Jour. Méd. Vet. et Zootech.*, 5. ser., 6 (1902), Dec., pp. 703-716, figs. 2).—The author made extensive observations on the anatomical effects of rabies upon different organs, especially parts of the nervous system. As a result of these observations, which confirm those already published upon the same subject, the author believes that as a rule in cases of natural infection by rabies in dogs well-marked lesions are produced in the plexiform ganglia and that where these lesions are not found it may be confidently concluded that rabies was not present.

Pseudorabies of dogs, A. TOMIOLO (*Gior. R. Soc. Accad. Vet. Ital.*, 51 (1902), No. 39, pp. 977-987).—Inoculation experiments were made for the purpose of diagnosing an apparent case of rabies. It was found, however, that all of the symptoms of rabies were not present in an apparently rabid animal and an inoculation of 8 rabbits with brain material obtained from the suspected animal gave negative results in all cases. Notes are given on the means of differential diagnosis between true rabies and this disease.

Pseudo-tuberculosis in dogs, DUCOURNEAU and P. JAYLES (*Rev. Vet. Toulouse*, 27 (1902), No. 8, pp. 501-508, fig. 1).—A detailed account is given of the appearance and development of this disease in a dog. A post-mortem examination was made, together with bacteriological tests. It is believed that the disease is due to a pathogenic organism which gains entrance into the venous system through the vessels of

the intestines. One of the symptoms is the appearance of enteritis, which later gives place to more serious symptoms, including tympanites. The pathological anatomy of this disease is described with special reference to the condition of the liver.

Treatment of eczema in dogs by subcutaneous injections with artificial serum, Pécus (*Jour. Méd. Vét. et Zootech.*, 5. ser., 6 (1902), Oct., pp. 601-602).—Good results are reported from the hypodermic injection of salt solutions in cases of eczema in dogs.

The effect of the injection of micro-organisms into the portal system on the sterility of the bile in the gall bladder, E. S. CARMICHAEL (*Jour. Path. and Bact.*, 8 (1902), No. 3, pp. 276-279).—The author's experimental investigations were made on rabbits, the micro-organisms being coli bacillus and Streptococci. Typhoid bacilli were also used on 1 animal. It was found that, in all these experiments except one, in the injection of micro-organisms into the portal system in quantities varying from 5 minims up, the bile retained its normal condition, thus indicating that micro-organisms can not pass through the normal hepatic tissue. Animals injected with *B. coli communis* and killed within 12 hours after the injection were found to possess absolutely sterile bile.

An epizootic among guinea pigs caused by a variety of coli bacillus, K. KOVÁRZIK (*Centbl. Bakt. u. Par., 1. Abt.*, 33 (1903), No. 2, Orig., pp. 143-149).—An outbreak of an epizootic nature occurred among the guinea pigs used for experimental purposes in the veterinary high school at Budapest. An investigation of the subject disclosed the fact that this disease was due to infection with a bacillus of the coli group. Notes are given on its growth and behavior on various culture media. Inoculation experiments were made on a number of animals. The organism was found to be pathogenic for rabbits, pigeons, guinea pigs, and sparrows. Dogs proved refractory. The bacillus was not destroyed by heat for 1 hour at a temperature of 60° C. A bibliography of the literature of this subject is appended to the article.

A new micro-organism which causes infection in animal pens, SCHWER (*Centbl. Bakt. u. Par., 1. Abt.*, 33 (1902), No. 1, Orig., pp. 41-48, figs. 2).—A study was made of an infectious disease which broke out among guinea pigs and other experimental animals in a laboratory. It was found that this organism produced an infectious disease of very rapid and fatal course. The clinical symptoms were therefore not very well defined. The post-mortem findings were, however, quite characteristic. The liver and spleen were greatly enlarged and exhibited extensive necrotic foci. The lungs were hyperemic and extensive microscopical alterations were produced in various organs. Notes are given on the appearance of the organism and its behavior on various culture media. It was found to be pathogenic for guinea pigs, rabbits, and mice, and appears to be most closely related to the bacillus of fowl cholera.

Determination of the value of fowl cholera serum, F. H. MOSLER (*Centbl. Bakt. u. Par., 1. Abt.*, 33 (1903), No. 3, Orig., pp. 230-235).—A number of cultures of fowl cholera bacillus were utilized in these experiments and the experimental animals were chickens and mice. It was found that in the use of a culture of fowl cholera bacillus so virulent that 2 lumps of the material would kill a mouse weighing 20 gm. within a period of 24 hours, a prophylactic effect could still be produced by the antiserum of Jess and Piorkowski, even if this serum had been kept for a period of 1 year.

MISCELLANEOUS.

Fifteenth Annual Report of Colorado Station, 1902 (*Colorado Sta. Rpt. 1902*, pp. 75-218).—This includes the organization list; a financial statement for the fiscal year ended June 30, 1902; a report of the director on the work of the station and substations, including a subject list of station publications; an inventory of station

equipment; a list of exchanges; and departmental reports, parts of which are noted elsewhere. Brief reports of the field agents and of the work done at the Plains Substation are also included.

Fifteenth Annual Report of Illinois Station, 1902 (*Illinois Sta. Rpt. 1902, pp. 16*).—This includes an enumeration of the principal lines of station work, a list of station publications, and a detailed financial statement for the fiscal year ended June 30, 1902.

Special Report of Illinois Station, February, 1903 (*Illinois Sta. Spec. Rpt. Feb., 1903, pp. 405*).—This report is made up of publications of the station relating to the live-stock, corn, soil, horticultural, dairy, and sugar-beet investigations which have been carried on by the station for nearly 2 years under State appropriations. Results obtained along the different lines are briefly summarized, suggestions are made as to future work, and a financial statement is included. More detailed progress reports, issued as Circulars 62-67, and noted elsewhere in this issue, are also made on the lines of work mentioned. The regular bulletins of the station included are Nos. 73-78 and 82-84.

Tenth Annual Report of Minnesota Station, 1902 (*Minnesota Sta. Rpt. 1902, pp. XIX + 265*).—This includes the organization list of the station; a report of the director containing a financial statement for the fiscal year ended June 30, 1902, and a review of the different lines of station work; a reprint of Class Bulletin 12, entitled Outline of Greenhouse Laboratory Work (E. S. R., 14, p. 870), and reprints of Bulletins 73-76 of the station on the following subjects: Growing swine of various breeds and crosses (E. S. R., 14, p. 284); human food investigations (E. S. R., 14, p. 274); fattening lambs (E. S. R., 14, p. 796); and fattening steers (E. S. R., 14, p. 794).

Fourteenth Annual Report of New Hampshire Station, 1902 (*New Hampshire Sta. Bul. 96, pp. 109-140*).—This includes the organization list of the station, a financial statement for the fiscal year ended June 30, 1902, reports of the vice-director and heads of departments, parts of which are noted elsewhere, a summary of meteorological observations, and a list of station publications available for distribution.

Director's report for 1902, W. H. JORDAN (*New York State Sta. Bul. 229, pp. 457-471*).—This is a report of the director upon the work of the station during the year. Notes are given on the station staff, mention is made of needed equipment, the results of fertilizer and feeding stuff inspection during the year are briefly summarized, and station work along the lines of bacteriology, botany, entomology, and horticulture is outlined. A list of bulletins published in 1902 is appended.

Twenty-fifth Annual Report of North Carolina Station, 1902 (*North Carolina Sta. Rpt. 1902, pp. 118*).—This includes the organization list of the station; reports of the director and heads of departments on the work of the station during the year; a financial statement for the fiscal year ended June 30, 1902; several miscellaneous papers noted elsewhere in this issue, and reprints of press bulletins on the hair snake (*Gordius variabilis*) and cotton anthracnose, and of Bulletin 181 of the station on silk culture (E. S. R., 14, p. 784).

Fifteenth Annual Report of Vermont Station, 1902 (*Vermont Sta. Rpt. 1902, pp. 193-352 + XXXVIII*).—This includes the organization list of the station; an announcement concerning the work undertaken by the station; a financial statement for the fiscal year ended June 30, 1902; a report of the director, containing a list of available station publications and a brief discussion of the relation of the station to the public and to the State; abstracts of Bulletins 88-94, and departmental reports abstracted elsewhere.

Reports of the agricultural experiment stations in Austria (*Ztschr. Landw. Versuchs. Oesterr., 6 (1903), No. 4, pp. 395-536*).—This includes reports of the following institutions for 1902: Agricultural experiment station for plant culture,

Brünn; experiment station of the Lower Austrian agricultural, horticultural, and viticultural school, Feldsberg; agricultural chemical experiment and seed control station, Gratz; seed control station of the agricultural secondary school, Kaaden; agricultural chemical experiment station of the Royal Imperial Agricultural Society of Carnithia, Klagenfurt; agricultural chemical experiment station for Carniola, Laibach; agricultural experiment station, Lobositz; agricultural chemical experiment station, St. Michael-on-the-Etsch, Tyrol; agricultural chemical experiment station of the agricultural council for Upper Austria, Otterbach, near Schärding; agricultural physiological experiment station of the Bohemian section of the agricultural council for the Kingdom of Bohemia at the Royal Imperial Bohemian Technical High School, Prague; experiment station for the brewing industry in Bohemia, Prague; experiment station for the sugar industry, Prague; Royal Bohemian Agricultural Academy, Tetschen-Liebwerd; experiment station for flax culture and the manufacture of flax products, Trautenau; agricultural botanical experiment and seed control station, Troppau, and agricultural botanical experiment station, Tabor.

Crop Reporter (*U. S. Dept. Agr., Division of Statistics Crop Reporter, Vol. 4, Nos. 10-12, pp. 8 each*).—These numbers are made up as usual of statistical information on the condition of crops in the United States and foreign countries, and are the issues for February, March, and April, 1903.

Our foreign trade in agricultural products, 1902, F. H. HITCHCOCK (*U. S. Dept. Agr., Division of Foreign Markets Circ. 35, pp. 24*).—This is issued as a supplement to Bulletin 27 (*E. S. R., 14, p. 304*), and gives statistics on the imports and exports of the United States during 1902. As compared with 1901 the agricultural imports increased from \$391,931,051 to \$413,744,557 and the agricultural exports decreased from \$951,628,331 to \$857,113,533.

The cotton-oil industry in America, D. A. TOMPKINS (*Cassier's Mag., 24 (1903), No. 1, pp. 45-54, figs. 10*).—The history and the present status and importance of the industry are discussed. The article contains a diagram showing the cycle of production, consumption, and land restoration in case of cotton.

Utilization of wood waste, E. HUBBARD, trans. by M. J. SALTER (*London: Scott, Greenwood & Co., 1902, pp. XVI-192, figs. 50*).—This is a translation of the second, revised and enlarged, German edition of this work, which contains, besides general remarks on the utilization of sawdust, chapters dealing with the use of sawdust as fuel with and without simultaneous recovery of charcoal and the products of distillation; the manufacture of oxalic acid, ethyl alcohol, dyes (organic sulphids and mercapto dyes); artificial wood and plastic compositions and wood compositions for molded decorations from wood waste; the employment of sawdust in the preparation of blasting powders and gunpowders, in briquettes, in the ceramic industry as an addition to mortar; the manufacture of paper pulp from wood; the production of wood wool, and miscellaneous applications of sawdust and wood refuse.

Unirrigated lands of eastern Colorado, J. E. PAYNE (*Colorado Sta. Bul. 77, pp. 16, figs. 4*).—The results of observations made by the author during 7 years' study of the soil, climate, natural vegetation, water supply, settlement, cultivated crops, and live stock industry of the Great Plains of eastern Colorado are recorded. "Stock raising must be the basis of all successful agricultural efforts in this region, and crop raising should be generally attempted as an aid to stock raising."

The Bermuda Islands; an account of their scenery, climate, productions, physiography, natural history and geology, with sketches of their discovery and early history, and the changes in their flora and fauna due to man, A. E. VERRILL (*New Haven, Conn.: Author, 1903, pp. X+548, pls. 40, figs. 280*).—The purpose of this volume is to give a convenient and comprehensive account of the history, natural features, and productions of the islands. It is intended for the use of tourists, students, and the inhabitants of the islands. The subjects considered

include general description, physiography, principal productions, exports, and changes in the flora and fauna due to man. The last-named part of the volume is further subdivided and contains a discussion of the character and origin of the native flora, the effects of deforesting, the introduction of useful plants, injurious weeds, and various species of animals, and the extermination of native birds. Especial attention is devoted to a discussion of the insects found in the Bermuda Islands. Among the numerous species of insects many of the more injurious pests common to the United States are noted. The parts of this volume dealing with climate and soils are noted elsewhere.

The Iowa yearbook of agriculture, J. C. SIMPSON (*Iowa Dept. Agr. Yearbook, 1902*, pp. 764, pls. 20, figs. 57).—This volume contains extracts from the Iowa road laws, an account of the State farmers' institute and agricultural convention and of a meeting of the State board of agriculture in 1902, together with a weather and crop report and the reports of the State college and of the State Dairy Commission. The proceedings are reported of the Improved Stock Breeders' Association, the Iowa Swine Breeders' Association, Iowa Dairy Association, and Iowa Park and Forestry Association. Notes are also given on various farm crops and live stock, statistics of the farms, crops, live stock, reports of county and district societies, and copies of a number of papers read before farmers' institutes.

Eighth report of the Bureau of Agriculture, Labor, and Industry of the State of Montana, J. A. FERGUSON (*Helena, Montana: Bureau Agr., Labor, and Ind., pp. VIII+733, pls. 30, figs. 82*).—A brief historical and descriptive account of Montana is presented, together with a discussion of the land, agricultural industries, live stock, labor, mines, various new industries, and miscellaneous matters relating to population, markets, assessed valuation, taxes, municipal ownership, libraries, sociological investigations, etc. Among the new industries special mention is made of various mining enterprises, the preservation of railroad ties, manufacture of macaroni, and development of oil fields.

Agricultural education in Hungary, J. SPEIR (*Trans. Highland and Agr. Soc. Scotland, 5. ser., 15 (1903), pp. 33-52, figs. 12*).—This is a general account of the development and present status of agricultural education in Hungary. There are at present 3 grades of institutions giving instructions in agriculture, viz, agricultural colleges at Magyar-Ovár and Debreczen; intermediate schools at Keszthely, Kassa, and Kolozsvár, and 21 farm schools. There are also 11 itinerant instructors in agriculture.

List of national, State, and local commercial organizations, and national, State, and local agricultural associations (*Washington: Govt. Printing Office, 1903, pp. 296*).

NOTES.

ARKANSAS STATION.—R. L. Bennett, director of the station since 1890, has resigned to go into private business. He left the station June 30.

COLORADO COLLEGE AND STATION.—W. L. Carlisle, professor of animal husbandry in the Wisconsin University and Station, has been elected agriculturist of the college and station and will take up his new duties in the fall. H. H. Griffin, field agent for the Arkansas Valley, located at Rocky Ford, has resigned to enter the employ of a sugar-beet company and has been succeeded by P. K. Blinn. The latter has charge of the cooperative experiments which the station is carrying on with the farmers in the valley, and is studying its agricultural development. The station at Rocky Ford has been rented to a progressive farmer, who is a graduate of the college, with the understanding that he will conduct experiments along certain lines without expense to the station.

FLORIDA UNIVERSITY.—The last legislature gave the university about \$60,000 for maintenance for the biennial period. The appropriation for buildings was declared unconstitutional in the form in which it passed. The veterinarian of the university and station was made *ex officio* State veterinarian. H. G. Dorsey, assistant professor of physics, has resigned to accept a position in a Rochester, N. Y., institution. The board at its last meeting abolished coeducation at the university.

HAWAII STATION.—Press reports state that the agricultural appropriations made by the Territorial legislature, which amounted as passed to \$41,600, includes \$7,500 in aid of the Federal experiment station.

IDAHO STATION.—J. S. Burd, assistant in the Bureau of Chemistry of this Department, has been appointed chemist to the Idaho Station, vice H. B. Slade who severed his connection with the station several months ago. Mr. Burd entered upon his duties July 1.

IOWA COLLEGE AND STATION.—F. R. Marshall, assistant in animal husbandry, has resigned his position to take charge of the live-stock work at the Brookmont Farm, Odebolt, Iowa, where the station has carried on extensive cooperative feeding experiments. He has been succeeded by W. J. Rutherford of Guelph, Canada.

KENTUCKY STATION.—Hon. F. A. Hopkins, Prestonburg, has been appointed a member of the board of trustees to succeed J. B. Marcum, deceased, and Dr. T. Carpenter, Scottsville, has been appointed to succeed B. W. Bradburn, resigned. D. W. May has been granted leave of absence during August and September and will spend the time in England and Scotland studying live-stock and breeding interests in those countries. George Roberts, assistant chemist, has resigned to accept a position in the chemical department of the California Station, in charge of the fertilizer control provided for by the recent act of the legislature of that State.

MAINE UNIVERSITY AND STATION.—At a recent meeting of the trustees of the university it was voted to establish a secondary school in agriculture with a two-years' course, entirely distinct from the college courses. The school will open the coming fall. It will consist of a fall, spring, and summer term the first year, and a fall and spring term in the second year, making a total of five terms aggregating sixty-two weeks. S. C. Dinsmore, a graduate of the university in the class of 1903, has been elected chemist, vice E. R. Mansfield, resigned.

MARYLAND COLLEGE AND STATION.—James S. Robinson, horticulturist, has retired from active charge of the horticultural work in the college and station, but will retain a nominal connection with the institution. M. M. Strong, M. S., has been elected assistant chemist to the station. Mr. Strong is a graduate of the Maryland college and has been for several years an assistant in the fertilizer inspection, but has spent the past year in special study at Johns Hopkins University.

MASSACHUSETTS COLLEGE AND STATION.—Francis Canning has been appointed instructor in floriculture and will have charge of the greenhouses. Neil F. Monahan, a graduate of the college, has been appointed assistant in the botanical department of the station, and G. F. Freeman, of Alabama Polytechnic Institute, assistant in the inspection work in botany, vice R. E. Smith. A general revision of the course of study has been made which will go into effect at the beginning of the new college year. Electives are offered during both the junior and senior years. The State board of agriculture has recently issued a special report by C. H. Fernald and A. H. Kirkland, on the brown-tail moth, which is now doing so much damage to fruit and shade trees in the eastern part of the State.

MISSOURI COLLEGE AND STATION.—H. J. Waters, dean and director, has been appointed superintendent of agriculture for the Missouri exhibit at the St. Louis Exposition and has been granted a leave of absence to take up this work. F. B. Munion has been appointed acting dean and director in his absence. An addition is to be built to the new horticultural building, which is now occupied by the departments of horticulture, entomology, and botany. The addition will be used for experimental work in botany along physiological, pathological, and ecological lines. A feeding shed 300 feet long and 30 feet wide is being built. This is intended primarily for the large feeding experiment which is being conducted in cooperation with the United States Department of Agriculture.

MONTANA COLLEGE AND STATION.—Samuel Fortier, director and irrigation engineer, has been granted leave of absence from the college and station for one year and has assumed charge of the irrigation work of this Office which is being carried on in California in cooperation with the State and the University of California.

NEBRASKA UNIVERSITY.—Frank G. Miller of the Yale School of Forestry has been elected professor of forestry.

NEW HAMPSHIRE COLLEGE AND STATION.—The State legislature has appropriated a total amount of \$40,000 for the college, \$15,000 of which is for general expenses, \$13,000 for equipping the new agricultural and horticultural building, \$7,000 for a greenhouse, and \$5,000 for additions to the heating plant. Edith M. Davis has been appointed purchasing agent of the college and clerk of the station in the place of F. C. Keith.

NEW YORK STATE STATION.—Milo H. Olin of Perry and Irving Rouse of Rochester have been appointed on the board of control, to succeed Oscar H. Hale and M. L. Allen, whose terms expired; and C. W. Ward of Queens, to succeed E. A. Callahan, deceased. The cattle barn, constructed to replace the one which was destroyed by fire last year, has been completed and the remodeled administration building is being occupied. Plans are under way for a new horse barn for which an appropriation of \$5,000 was made by the last legislature, and for a fire protection system to cost \$5,000.

CORNELL UNIVERSITY.—Owing to the failure of the State to appropriate means for the maintenance of the college of forestry, established by the State at Cornell University, the trustees of the university have decided to suspend instruction in that college until the means for its maintenance are provided by the State, and have declared all positions on the instruction force, including that of director, vacated. There was a prospect of an attendance of about one hundred students at the school next fall.

OHIO UNIVERSITY AND STATION.—Thomas F. Hunt has resigned his position as dean and professor of agriculture in the university, to become professor of agronomy at Cornell University. He entered upon his new position July 1. H. C. Price, a graduate of the university and recently horticulturist at the Iowa College and Station, has been elected dean and professor of rural economics, and M. F. Miller has been made assistant professor of agronomy. John F. Hicks, assistant botanist at the Ohio Station, was shot by an unknown person just as he was preparing to leave Wooster the night of May 31. Mr. Hicks had resigned his position to engage in business in Cleveland.

OKLAHOMA COLLEGE AND STATION.—J. F. Nicholson, of the New York State Station, has been appointed assistant in bacteriology in the college and station. Provision has been made for the appointment of an assistant in agriculture. C. O. Percy, clerk and stenographer, has resigned.

PENNSYLVANIA COLLEGE.—The total appropriation for the college made by the State legislature at its recent session was \$250,805.55. Of this amount \$100,000 is for the purpose of assisting in the erection, equipment, and furnishing of a building for the department of agriculture of the college, while \$150,000 additional is virtually pledged by the attachment of a proviso requiring the trustees of the college to file with the auditor-general plans, specifications, and estimates satisfactory to him showing that the entire cost of the building and equipment will not exceed \$250,000. At no stage in the progress of the bill through the legislature was a single vote recorded against it. The amount was voluntarily increased by the appropriation committee from \$223,000 to \$250,000. The college announces the resumption of the short course in agriculture, which has been suspended for the past four years. The course next winter will begin January 6 and continue until March 30. The short creamery course will begin at the same time and close March 2.

SOUTH CAROLINA COLLEGE AND STATION.—The board of trustees has voted to erect an agricultural building to cost \$50,000, providing full accommodation for the agricultural department and its various divisions. J. S. Newman has been appointed director of farmers' institutes. It was planned to hold thirty-one local institutes during the month of July, and a State institute to be held at the college August 10 to 14.

UTAH COLLEGE AND STATION.—G. L. Swendsen, professor of civil engineering and hydraulic engineer to the station, has resigned to accept an appointment with the U. S. Geological Survey. W. M. McLaughlin, a graduate of the college in 1895, has been appointed his successor in the station, and will give his whole time to the station work. W. D. Beers, assistant irrigation engineer, has severed his connection with the college and station. In accordance with the recent provision of the State legislature 6 farms have been located by the station in different parts of the State for experiments in dry farming. These include 40 acres each, and were donated in each case by the county, which also paid the expense of clearing and fencing them. No buildings or permanent equipments will be provided, the team work being hired. A competent laborer will be placed in charge of each farm, and the station will exercise a close supervision of the work. Trials will be made mainly with grains and forage crops grown without irrigation.

VERMONT STATION.—F. M. Hollister, B. S., of the class of 1903, has been appointed assistant chemist.

WASHINGTON STATION.—The State Station at Puyallup has been closed and the land rented to local parties who will look after the plants and fruits now growing. The legislature passed an appropriation of \$12,000 for the station, but the bill failed to receive the governor's signature.

WEST VIRGINIA COLLEGE AND STATION.—John L. Sheldon, of the botanical depart-

ment of the University of Nebraska, has been appointed professor of bacteriology in the university and station, and will enter upon his duties September 1.

FLORIDA AGRICULTURAL INSTITUTE.—The legislature of the State of Florida at its recent session provided for the establishment of an agricultural institute, for practical instruction in that subject, to be located at Kissimmee. An appropriation of \$5,000 was made for establishing the institute, and \$5,000 for its maintenance for two years.

CALIFORNIA POLYTECHNIC SCHOOL.—The first annual catalogue of this new school has recently been received. The State legislature in 1901 appropriated \$50,000 for the establishment of the school, and it was located on a 280 acre tract of land near San Luis Obispo. The past winter the legislature appropriated \$64,400 to complete the buildings undertaken, and for equipment and maintenance during the biennium. It is distinctly stated that the institution will not be of the college grade, and will not aim to prepare students to enter a higher institution of learning. "Its course of study is arranged solely in view of the needs of the boy and girl who are going to earn a livelihood after completing its course." This covers three years. The work of the first two years is prescribed for all students, and includes both agriculture and mechanics for the boys and domestic science for the girls. The third year about one-half the course is elective. The instruction will be both theoretical and practical, and much of the work on the farm and in erecting frame buildings for the farm will be done by the students. Two buildings, an admission building and a dormitory, each having two main floors and a high basement, are approaching completion. The school will open in September, and the prospects for the entering class are already good. The director, it will be remembered, is Dr. Leroy Anderson, formerly of the New York Cornell Station, and more recently of the California University and Station.

JAPANESE EXPERIMENT STATIONS.—The successful work of the local agricultural experiment stations in Japan has made it possible for the Ministry of Agriculture and Commerce to reduce the number of branch experiment stations connected with the Central Agricultural Experiment Station at Nishigahara, and to concentrate its efforts and funds on a smaller number of stations and fewer lines of work. Until April, 1903, there were 9 of these branch stations, but at that time 6 of them, viz, the Hokuriku, Toei, Tokai, Shikoku, Sanio, and Sanin branch stations, were turned over to the control of the local governments, and the funds and staffs of these institutions were transferred to the Central Agricultural Experiment Station, and the 3 remaining branch stations, i. e., those at Kashiwabara, Idzumimura, and Hanadatemura. The funds available for the Central Station and its 3 branches for the fiscal year ending March 31, 1904, amount to \$91,920. The total budget of the Ministry of Agriculture and Commerce for the same year is \$3,386,713. The local stations referred to above now number 39. They receive subsidies from the Ministry of Agriculture and Commerce amounting to \$65,000 a year and also funds appropriated by the local governments. The annual expenditures of these stations vary from \$2,200 to \$11,232. In addition to the stations supported by public funds, there are 3 private experiment stations. The island of Formosa supports 3 agricultural experiment stations and a tea experiment station, all of which are under the control of the Bureau of Industries of Formosa.

TOUR OF THE GERMAN AGRICULTURISTS.—The party of forty-four gentlemen, mostly landowners and members of the German Agricultural Society, who had been on a tour of this country since May 2, concluded their trip in New York June 24. The party visited points of agricultural interest in eighteen different States, and traveled for that purpose about 11,000 miles. At the request of the German Agricultural Society the itinerary of the trip had been arranged in this Department, and Mr. J. I. Schulte, of this Office, accompanied the party as conductor. A slight change was

made to allow the visitors to go through the Yellowstone National Park, which was not originally included in the instructions from the society.

Considering the prominence of the gentlemen composing the party, and their intelligence in matters pertaining to agriculture, their impressions are interesting. In general it may be said that they found much to approve and admire, and that their criticisms were frank and fair minded, although they often failed to take into consideration the local conditions which prevail in this country. They commented very favorably upon the work of this Department in general, and especially approved its efforts to solve the practical problems of immediate interest to agriculture. The wide distribution of information by the Department strongly appealed to them.

Agricultural colleges and experiment stations were inspected in Kentucky, Iowa, California, Oregon, Minnesota, and Wisconsin. These institutions were considered well equipped for imparting scientific and practical knowledge, and consequently looked upon as one of the greatest factors in the rapid development of American agriculture. The methods of teaching stock judging met with hearty approval, and some of the party expressed themselves in favor of more rapid development of this feature of agricultural instruction in their own schools. As might have been expected, the military instruction given at the agricultural colleges proved of much interest. Exhibition drills were given at the Iowa and Oregon colleges, and the work of the cadets was commended.

Some surprise was expressed that in building up a dairy herd the American farmer evidently considers practically only the milk and butter production, while in Germany considerable attention is given to making the individuals of a herd alike in color and in form. The large milk and butter records called to their attention were generally looked upon with suspicion. The method of stabling cows in stalls with short floors and in stanchions was not approved of, although it was conceded that the animals might be kept more clean; this, however, at the sacrifice of comfort.

In studying horse raising and breeding, the greatest interest was exhibited in the breeds of distinctively American character, such as the Kentucky thoroughbred and the standard-bred horses. The desire of the visitors in general was not so much to see fine stallions or be impressed with track records, as to find out how the colt is reared, broken, and sold; how much it costs to produce a horse, and what is realized for him when placed on the market. In looking over draft horses, their interest was centered less on imported animals than on the generations produced on American soil and under American management.

The beet-sugar industry was an object of much interest, and they were favorably impressed with what they saw of the beet fields and factories; but considering the labor and other economic conditions in this country, the opinion prevailed that Germany presents certain advantages and that the competition of this country is likely to prove less serious than has been anticipated.

The agriculture, horticulture, and forestry of the Pacific Coast States received in general most favorable comment. That section of our country impressed itself upon the foreign visitors largely through its diversity in products and its fine tree growth. The reclamation of the "tule" lands in California proved of highest interest.

Perhaps the deepest impression was made by our forest conditions. The unanimous verdict of the party was that our management of the trees was extremely wasteful. Many were of the opinion that the day when the United States will import lumber is bound to come soon unless a radical change in our methods is made in the near future. The many fallen timbers and the evidences of comparatively recent forest fires in the Yellowstone Park were an eyesore to the party, and made it impossible for them to fully enjoy one of our greatest natural attractions.

The general conclusion of the visitors was that while they had seen many interesting features of agriculture in the United States, and were highly impressed with its rapid development and progress, the conditions here were so different that very few of our methods were directly applicable to agriculture in Germany.

ECONOMICS OF FARM MANAGEMENT.—The first part of a Syllabus of Lectures on Agricultural Economics, by Dr. Henry C. Taylor, of the University of Wisconsin, has been received. This first part is devoted to the economics of farm management, and is based upon a course of lectures delivered by the author during the past winter to the second-year short-course students in the college of agriculture. Following the introductory, there are chapters on crops and field systems—European and American, intensity of culture, productivity, the size of farms, prices of agricultural products, distribution of gross returns, the price of land, land tenure in the United States, means of acquiring land ownership, and the renting of land. "The writer makes no pretensions of having presented here a complete outline of the subject. The needs of the students and the material which the author had in hand determined the character of the course of lectures. Practically all of the time has been given to private agricultural economics, because the subjects included under this head are of more immediate interest to the farmer. The author hopes to find time to work this subject out much more completely in the near future."

MISCELLANEOUS.—Elwood Mead, in charge of irrigation investigations of this Department, has gone to Italy for the purpose of making a study of the methods of distributing and using water in that country, and the kinds and value of crops grown by irrigation. The annual rainfall in Italy being nearly 40 inches makes irrigation a matter of choice rather than of necessity, and gives the results a significance to irrigators in the eastern part of the United States which irrigation in arid countries like Egypt does not have. Mr. Mead will spend a month or more in the valley of the Po studying the irrigation systems in Lombardy and Piedmont. He will ascertain, if possible, how rivers are controlled, either by the State or by private interests, and will gather statistics of the prices paid for water, the amounts used, the way in which it is applied to crops, and the differences in products, yields, and value on irrigated and unirrigated land. In connection with his trip Mr. Mead will make briefer observations of irrigation in Switzerland and possibly southern France and Spain. If his time permits he will inquire into what is being done in the application of power to farm work, in the pumping of water and in irrigation and drainage, and what the agricultural experiment stations are doing to determine the efficiency of agricultural machinery.

Prof. W. O. Atwater, in charge of nutrition investigations of this Office, has gone to Europe, where he will spend the summer and fall in studying the progress of investigations on human nutrition in the leading laboratories and other institutions of England, France, Belgium, Switzerland, Italy, Austria, Germany, and, perhaps, Denmark and Sweden. He expects to return about the end of November.

Gifford Pinchot, Chief of the Bureau of Forestry of this Department, has been elected professor of forestry in the Yale Forest School. This appointment will make no change in his relation to the Bureau of Forestry, and will but slightly increase the work he has been doing for the school in the past. He will deliver a short course of lectures at New Haven during the first two weeks of November.

Prof. William H. Brewer has resigned the professorship of agriculture at the Sheffield Scientific School, Yale University, and has been appointed professor emeritus. The university conferred the degree of LL. D. upon him at the recent commencement.

Luther Burbank, of Santa Rosa, Cal., was awarded a gold medal by the California Academy of Sciences on the recent occasion of the celebration of its semi-centennial anniversary. This was the highest honor conferred by the academy, and was awarded to Mr. Burbank for "meritorious work in developing new forms of plant life."

Prof. Thomas F. Hunt has received the degree of Doctor of Agriculture from the University of Illinois.

W. C. Welborn, formerly of the Mississippi Agricultural and Mechanical College, has gone to the Philippines, where he will be connected with the Bureau of Agriculture.

T. D. A. Cockerell, of the Normal University, at East Las Vegas, N. Mex., and consulting entomologist of the Arizona Station, has accepted a position in Colorado College, at Colorado Springs.

Harvard University has established a course in forestry, and R. T. Fisher has been appointed instructor in this subject.

We note from *Science* that L. Daniel has been elected to a newly established chair of agricultural botany at the University of Rennes.

The American Association of Farmers' Institute Workers held its annual meeting at Toronto June 23-26. The officers elected for the coming year were: President, B. W. Kilgore, of North Carolina; vice-president, E. E. Kaufman, of North Dakota; secretary, G. C. Creelman, of Ontario; executive committee, the president, secretary, and George McKerrow of Wisconsin, H. C. Easterly of Illinois, and J. C. Hardy of Mississippi. The meeting next year will be held at St. Louis.

The Seventh Annual Convention of the National Association of State Dairy and Food Departments was held at St. Paul July 21-24. The programme was a long one and included papers and discussions on food legislation, food standards, manufacture and preservation of foods, antiseptics, labeling, etc.

A bill has passed the State legislature of Massachusetts providing for the manufacture of vaccine lymph for free distribution in the State and placing this under the control of the State board of health. The lymph will be manufactured at the Bussey Institute. A bill appropriating \$250,000 for combating the gypsy moth has been rejected.

We note from *Nature* that the annual report of the Royal Agricultural Society, adopted at the meeting held May 22, states that the council of the society has decided to organize an agricultural education exhibition as a new feature of its annual show, with a view to bringing before the public the general characteristics of the teaching now provided at agricultural colleges, and of drawing attention to the society's own share in this work as a national examining body.

The board of agricultural studies of the University of Cambridge reports that, during the past year 169 students have received instruction in agricultural science. The income of the department is about \$18,000. The need of a permanent building to accommodate the various branches of this work is becoming apparent and the matter is receiving the consideration of the board.

It is reported that the Viceroy of India will devote the £20,000 donated by Henry Phipps to the establishment of a laboratory for agricultural research, to be known as the Phipps Laboratory, and to be situated at Dehra Dun, and to a second Pasteur institute in the south of India. The donation will be devoted to providing the buildings. The government will contribute toward the maintenance of the agricultural laboratory and bear the whole expense in the case of the Pasteur institute.

EXPERIMENT STATION RECORD.
